Man, Isle of, the ancient *Mona*, an island in the Irish Sea, 33 miles west of England, 30 miles east of Ireland, 16 miles south of Scotland, and 56 miles north of Wales; greatest breadth 12 miles; length, north-east to south-west, 33 miles.

Climate.—Recent observations enable us to give more accurate and detailed climatic statistics than were possible in 1882. The mean annual temperature of the 70 years between 1828 and 1897 was 49°0', that of the summer being 57°2' and of the winter 42°0'. The mean variation between the warmest month (August), 58°5', and the coldest (January), 41°4', was 17°. The annual rainfall varies greatly in the different districts, the calculated mean of 70 years (1828-97) giving 61 inches on the summit of Snaefell, 47 inches at Ramsey, 46 inches at Douglas, 38 inches at Peel, 34 inches at Castletown, 28 inches at the Point of Ayre, and 25 inches at the Calf of Man. Observations of bright sunshine show the Isle of Man to be one of the sunniest places in the British Isles.

Minerals.—In 1899 the value of the lead obtained was £59,210; of the zinc, £24,701; and of the silver, £8236. The value of the granite quarried was £2445.

Agriculture.—In 1900 the total acreage under all kinds of crops, bare fallow, and grass was 92,184, of which

21,890 acres were under corn crops (oats, 13,393; barley, 7382; wheat, 814; rye, beans, and peas, 301), 10,938 acres under green crops, 39,238 acres under rotation grasses, and 20,118 acres under permanent grass, &c. There were also 25,781 acres of mountain pasture and 1026 acres of orchards, woods, and market-gardens. Horses, 3399 of which were used solely for agriculture, numbered 5139; cows, 21,988; sheep, 75,047; and pigs, 2679.

Trade.—In 1900 the tonnage of vessels cleared for coastwise traffic was 717,150, and for foreign and colonial traffic, 668. The number of vessels (other than fishing-boats) registered as belonging to the Isle of Man in 1900 was 91, and their tonnage was 13,233. In the same year there were 308 fishing-boats aggregating 5103 tons, which employed 1470 men and 212 boys.

Internal communication has been much facilitated by the provision of tramways along Douglas Bay¹ (1883), between Douglas and Laxey² (1895), between Laxey and the summit of Snaefell² (1896), in Douglas³ (1897), and between Laxey and Ramsey² (1898).

Population has remained almost stationary since 1881. Total (1891), 55,608; (1901), 54,758. In 1901 the population of Douglas was 19,149; of Ramsey, 4672; of Peel, 3306; and of Castletown, 1963.

Births, Marriages, and Deaths.—The following are the rates per thousand of the population for five-year periods between 1884 and 1898:—

	Births.	Marriages.	Deaths.
1884-88	28·1	6·97	20·6
1889-93	26·4	6·81	19·8
1894-98	25·6	7·10	19·4

Language.—The Manx language still lingers, the census of 1901 showing that there were still about 4400 people who understood something of it. There is now no one who does not speak English.

Elementary Education.—Total number of schools 53, 42 being Board and 11 denominational (6 Church of England, 3 Wesleyan, 2 Roman Catholic). Percentage of attendance, 85·41; average attendance, 8206. Amount of Government grant per child, 19s. 8·4d. Receipts from rates, £8794; total expenditure, £30,222.

Rateable Value.—The rateable annual value of the parishes, towns, and villages was £392,528 in 1900.

Revenue for the year ending 31st March 1902 was £78,382, and the expenditure £75,542. The present debt is £160,224. The largest revenue raised was £91,339 in 1901, and the debt reached its maximum amount, £219,531, in 1894.

Poor Relief.—The total number of persons in receipt of poor relief in 1900 was 934, and its cost was £4842.

Lunatics numbered 206 in 1901; their cost was £4168.

HISTORY.

Constitutional.—On the departure of the duke of Atholl in 1829 the Tynwald Court had no control over the surplus revenue, and this continued to be the case till 1866, when it gained, if not the sole control of this revenue,⁴ at least a substantial share in the disposal of it. Since 1866 it has also obtained a real instead of a nominal voice in fixing the customs duties, subject to the veto of Parliament or the Treasury; and of late years it has become the practice for this court to elect a committee of its members to advise the Governor in financial matters.

The change of the House of Keys in 1866 from a self-elected to a representative body has already been referred to (vol. xv. p. 452). In 1880 it established its right to regulate its own sittings, which had been disputed. The

¹ Horse. ² Electric. ³ Cable traction.

⁴ In the article in vol. xv. it was stated in error that the Keys gained the control of the surplus revenue in 1866.

property qualification of the members of the House of Keys was abolished in 1892. In 1881 the franchise was lowered and extended to women, being conferred upon every person who (1), being a male, or a spinster or widow, is the owner of real estate of the annual value of not less than £4; or (2), being a male, is the occupier of real estate of the annual value of not less than £4; or (3), being a male, occupies lodgings of the annual rental of not less than £10. In 1892 women who were occupiers of real estate worth not less than £4 annually were also given a vote.

In 1883 the whole Manx judicial system was transformed. Law and equity were fused, and the whole legal and equitable jurisdiction of the various courts was transferred to the High Court of Justice. The effect of this and other changes has been virtually to assimilate, with very few exceptions, the Manx practice in the administration of justice to the English. The office of Water-Bailiff was done away with in 1885.

Ecclesiastical.—In 1878 a Sodor and Man Theological School was established for the training of candidates for holy orders. This school has been affiliated to Durham University. In 1880 four rural deaneries were established, and commissioners were constituted as trustees of endowments for Church purposes. In 1895 a cathedral chapter, with four canons, was constituted under the name of the "Dean and Chapter of Man," the bishop being the dean of the cathedral church. A Church Sustentation Fund was established by Bishop Straton in 1894, with a view to supplementing the incomes of the clergy, which had been greatly reduced on account of the low price of corn. Since 1884 the jurisdiction of the Church courts has almost disappeared, all that now remains having reference to affiliation questions, the swearing in of churchwardens, and the granting of faculties. There have been several Acts giving Nonconformists equal rights with Churchmen. Among these are the Burial Acts of 1881 and 1895, which permit burials to take place in churchyards without the rites of the Church of England, and allow any burial service, provided it be Christian, in mortuary chapels.

Social and Economic.—It was not till 1872, when the insular Legislature passed the Public Elementary Education Act, that the Manx State undertook any direct responsibility for education. This Act differed from the English Act of 1870 in three important particulars: (1) It at once constituted every town and parish a school district under a school board; (2) the attendance of children was made compulsory; and (3) every elementary school, those in connexion with the Church of Rome excepted, was obliged to provide for non-sectarian instruction in religious subjects, and for the reading of the Bible accompanied by suitable explanation. Since the date of this Act education has made extraordinary strides. It became free in 1892, and a higher-grade school was established in Douglas in 1894. In 1876 vaccination was made compulsory, as also was the registration of births, marriages, and deaths in 1878. It was not till 1884 that the sanitation of the towns was seriously taken in hand, but ten years more elapsed before the sanitary condition of the island was dealt with by the passing of an Act which constituted parish and village districts, with commissioners elected by the people, who had, in conjunction with a board elected by the Tynwald Court and an inspector appointed by it, to attend to all questions relating to sanitation and infectious diseases. As a result of these measures the death-rate has been greatly reduced. In 1888 a permissive poor law was established; it has been adopted by all the towns except Peel and by six of the seventeen country parishes. Prior to this date the poor had been dependent on voluntary relief, which broke down owing to the growth of a temporarily em-

ployed class occupied in administering to the wants of the summer visitors. In 1829 the insular harbours were practically unprotected from inshore winds, there was no low-water landing accommodation, and no regular communication with England by steamer. But since 1860 extensive harbour works have been constructed which give great, though still inadequate, protection, and nearly all the landing accommodation required; and steamers run to and from England on every week-day during the year. Since 1844 numberless absurd and complicated regulations, which hampered trade, have been revoked, and, while the duties on spirits have been increased, those on articles of beneficial and universal consumption have either disappeared or have been greatly reduced. In 1853 the infamous licence system, by which only limited quantities of such articles as spirits, tea, coffee, tobacco, and salt could be imported, and then only by a few merchants, who, having obtained a licence, combined and charged what prices they pleased to the unfortunate consumers, was abolished.

Manx textile industries have, generally speaking, declined since 1880, being unable to compete with the larger and more completely organized manufactories elsewhere. Agriculture has, on the whole, improved since 1882, and its average condition in 1902 was not much inferior to what it was in England and Scotland. In 1900 commissioners appointed to inquire into the condition of local industries noted that there was need for better and more complete cultivation of the land, and that, as regards the crops, "neither Manx wheat nor barley is as good on an average as English; but that oats, the largest crop, is on the whole fully equal to what is grown on the mainland." They stated that the Government premiums for stallions and bulls, which had been established in 1889, had been beneficial in improving the breed of horses and cattle, but that dairying was in a very unsatisfactory condition and butter "very unequal in quality." The fishing industry is a declining one. Efforts to deal with this state of affairs have been confined to the making of bye-laws regulating the sea-fisheries in 1894, and to the erection of a hatchery for lobsters and flatfish at Port Erin in 1902. Mining, on account of the low price of metals, is also on the wane. The discovery of an excellent quarry of granite at the Dhoon has led to the production of paving setts on a large scale. But there is one industry, for so it may really be called, that of providing for summer visitors, which has greatly prospered, and the Isle of Man has become the most popular holiday resort in the north of England. On the whole, it may fairly be said that the Manx people in 1902 formed a prosperous and contented community.

During the ten years 1891–1901 a considerable number of books relating to the history, law, antiquities, language, folklore, and philology of the Isle of Man have been issued. The chief of them are mentioned in the list given below. The most popular literary associations of the island, however, are those which centre round the novels of Mr Hall Caine, who, in his *Deemster, Manxman, &c.*, has exploited the "local colouring" of the island in a way which has undoubtedly added to its general interest.

Manacor, a town in the island of Majorca, 11 miles from its eastern shore, and connected with Palma by rail. Its population was 16,461 in 1887, and 11,579 in 1897. A suburb of some importance has sprung up by the sea, styled Colonia del Carmen, with good modern houses.

Managua, the capital of Nicaragua, Central America, situated 1 mile from the foot of Lake Managua, 32 miles south-east of Granada, with which it is connected by rail. There is communication with Momotombo at the head of the lake by small steamers, and thence by rail 58 miles to the port of Corinto. It was chosen as the capital of Nicaragua in 1855, and on account of the improved railway communication with Corinto and with the interior its commercial importance has considerably increased, its chief trade being in coffee, of which the plantations in this district have almost superseded those of cotton. The principal building is the Palacio Nacional, in the Corinthian style. A modern addition is the national, industrial, and scientific museum. Population about 18,000.

Manahiki. See POLYNESIA.

Manaoag, a town in the north central portion of the province of Pangasinan, Luzon, Philippine Islands. There is rich agricultural land in its vicinity, which is level for the most part, and its inhabitants devote themselves almost exclusively to rice-culture. The principal language is Pangasinan. Population, 17,000.

Manaos, a town in Brazil, at the mouth of the Rio Negro, and capital of the province of Amazonas, with a population estimated at between 30,000 and 50,000. It is an important commercial mart, especially for the fine Upper Amazon rubber, large quantities coming from Bolivia. Some 8200 tons of this commodity were exported in 1899-1900. It is connected with Pará by a cable down the Amazon, and a railway is projected up the Rio Madeira, which will greatly increase the business of Manaos. Though the town is of recent origin, it already possesses electric tramways, waterworks, electric street-lighting, and a fine opera-house.

Manbhum, a district of British India, in the Chota Nagpur division of Bengal. The administrative headquarters are at Purulia.

Area, 4147 square miles; population (1881), 1,058,228; (1891), 1,193,325; (1901), 1,303,583, showing an increase of 13 per cent. between 1881 and 1891, and of 9.24 per cent. between 1891 and 1901; average density, 314 persons per square mile. Classified according to religion, Hindus numbered 972,509 in 1891; Mahomedans, 53,255; Christians, 1532, including 78 Europeans; aborigines, 166,029. The land revenue and rates in 1897-98 were Rs.1,47,403; number of police, 353; number of boys at school (1896-97), 17,283, being 19.4 per cent. of the male population of school-going age; registered death-rate (1897), 32.74 per thousand. Manbhum contains the Jherriah coalfield, in the Damodar valley, where a large number of mines have been opened since 1894. Some of these are very small; but three employ more than 1000 persons each, with an output of more than 100,000 tons. The United Free Church of Scotland has a mission at Pakheria, with a printing-press that issues a monthly journal in Sonthali. The district is traversed by the Bengal-Nagpur railway, with another line to the coalfield.

Manche, a department of the north-west of France, forming the peninsula of Cotentin, washed by the English Channel.

Area, 2475 square miles. The population, 520,865 in 1886, decreased to 488,631 in 1901. Births in 1899, 10,867, of which 790 were illegitimate; deaths, 10,695; marriages, 3620. The schools numbered in 1896, 1233, with 71,000 pupils, and the illiterate constituted 3 per cent. of the population. Out of 1,284,994 acres of cultivated land in 1896, 778,409 acres were plough-land and 420,094 acres natural pastures and grass lands. The wheat of 1899 yielded the value of £718,000; barley, £312,000; buckwheat, £348,000; oats, £188,000. Its chief wealth, however, consists in its vast natural pastures and grass lands, which in 1899 returned a value of £2,080,000, and in respect of which Manche holds a front rank among the departments of France. Apples rendered in 1898 the value of £837,000. The live stock of 1899 included 81,780 horses, 316,750 cattle, 179,350 sheep, and 112,870 pigs. The total value of the milk of the department was in 1899 £2,600,000. Manche has, however, no industries of importance, with the exception of paper factories and some spinning mills. Saint Lô, the capital, had 11,604 inhabitants in 1901; but Cherbourg (42,952 in 1901) is the largest town.

Manchester, a county of itself, city, parliamentary and municipal borough and parish, in the south-east of the county of Lancashire, England, the commercial centre of the English cotton district. With the borough of Salford, with which it is continuous, Manchester is about 180 miles north-east of London, in 53° 29' N. and 2° 14' 23' W. They stand on a level plain and on the rising ground to the north. The rivers are the Irwell, Medlock, Irk, and Tib. There are stations on the London and North-Western, the Midland, Great Northern, and Great Central railways. There are about fifty passenger stations in the two boroughs, which are connected by rail with every part of the kingdom. The parliamentary and municipal boroughs of Manchester are not conterminous. The city boundaries were enlarged in 1885 from 4294 acres to 5933 by the inclusion of Bradford and Rusholme. In 1890 the addition of Blackley, Kirkmanshulme, Moston, Newton Heath, Openshaw, and West Gorton, with some minor readjustments in 1894, made the municipal area 12,911 acres. The population of the city was 505,368 in 1891, and 543,969 in 1901. The parliamentary borough contains 7945 acres, and had a population of 454,509 in 1891 and 475,455 in 1901, divided amongst six divisions. The parliamentary and municipal boundaries of Salford are identical, the area being 5170 acres, and the population 198,139 in 1891 and 220,956 in 1901. Both boroughs have as neighbours populous towns and urban districts. Tramways, as well as railways, run from Manchester to Oldham, Ashton, Eccles, Stockport, &c., with which places the city is connected by continuous lines of street. The length of the streets in the city of Manchester is 694 miles, and in the same area there are 78 miles of tramways.

Parks and Statues.—There are in Manchester thirty-nine parks and open spaces. Some of these are small, and the total area is 1103 acres. Boggart Hole Clough, where great efforts have been made to preserve the natural features, is 76 acres in extent, and was the largest until 1902, when Heaton Park, containing 692 acres, was purchased at a cost of £230,000. It was formerly the seat of the earls of Wilton, and includes Heaton House, one of Wyatt's structures. In the Queen's Park there is a museum, and periodical exhibitions of works of art are held. There, too, is a statue of Benjamin Brierley, a well-known writer in the Lancashire dialect. The Salford parks have an area of about 130 acres. The largest is Peel Park, in which there is a museum, library, and art gallery. The last-named, built from the bequest of Mr E. R. Langworthy, contains some notable paintings. The statues are not numerous. There are several in the Manchester town hall. In Piccadilly are statues of Sir Robert Peel, Dr Dalton, and

the Duke of Wellington. In Albert Square are statues of the Prince Consort, Bishop Fraser, John Bright, Gladstone, and Oliver Heywood. In St Ann's Square is a statue of Cobden. A statue of Dr J. P. Joule in the town hall should also be named. The Whitworth Park occupies an exceptional position, as it is not the property of the Manchester corporation, but of the Whitworth Institute, a

corporate body originating from the liberal bequests of Sir Joseph Whitworth. The Institute contains a valuable collection of works of art, and stands in the centre of the park, which is maintained as a woodland park and pleasure-ground. In the park is a sculpture group of Christ and the Children by George Tinworth from the designs of Mr R. D. Darbishire, by whom it was presented. A Diamond Jubilee

PLAN OF MANCHESTER.

statue of Queen Victoria stands in Piccadilly, and another statue of her Majesty by Princess Louise, Duchess of Argyll, is placed on the new porch of the Cathedral.

Public Buildings.—The chief public buildings are the Royal Infirmary, which occupies a central position in Piccadilly, and the Town Hall, erected at a cost, including interest, of £1,062,565. Around the great hall are a series of twelve mural paintings by Mr Ford Madox Brown. The organ cost £5269, and the bells and clock £6985. The town hall was opened in 1877, and contains 314 rooms. There are also eleven district town halls and public rooms belonging to Manchester. Salford, Pendleton, and Broughton have each a town hall. The Man-

chester post office, Brown Street, is a handsome building, completed in 1887. It suffers, like many other fine structures in the city, from being hemmed in by streets, which prevent the proportions from being seen to advantage. Other public buildings are the Free Trade Hall, the Royal Exchange (1869), the Assize Courts (1864), and the city police courts (1871). The Royal Institution was transferred to the corporation in 1882, and the permanent collection of works of art then existing has been considerably increased by purchases, to which purpose £2000 is yearly devoted. It is known as the City Art Gallery.

Manchester Ship Canal.—The most important event in the modern history of the district is the creation of the ship canal, by

which Manchester and Salford have a direct communication with the sea at Eastham, near Liverpool. The idea of making Manchester a port was an old one. After various schemes had been proposed, and after a long and costly parliamentary struggle, the work of construction was begun in November 1887 under the superintendence of Mr (afterwards Sir) Edward Leader Williams, as engineer. Mr T. A. Walker, who was the contractor, died in 1889, and the completion of the work was taken over from his executors by the company and finished under contracts. The canal was opened for traffic in January 1894. The official opening ceremony was on 21st May 1894, when Queen Victoria visited Manchester. The total expenditure on capital account has been £15,173,402, including £1,224,451 paid for land and compensation and £1,786,313 for the Bridgewater canal, now absorbed in the greater undertaking. The original share capital of £8,000,000 and £1,812,000 raised by debentures having been exhausted, the corporation of Manchester advanced on loan a further sum of £5,000,000. (For the engineering features see CANALS: *Ship Canals*.) The Manchester canal is a remarkable example of constructive skill; and whilst the original shareholders have not received the anticipated returns from these investments, the canal has had a beneficial influence on the trade and the district. Since the opening for traffic the yearly tonnage has been :—

	1894. Tons.	1895. Tons.	1896. Tons.	1897. Tons.
Sea-borne traffic	686,158	1,087,443	1,509,658	1,700,479
Barge traffic	239,501	271,432	316,579	365,336
Total	925,659	1,358,875	1,826,237	2,065,815
	1898.	1899.	1900.	1901.
Sea-borne traffic	2,218,005	2,429,168	2,784,843	2,684,833
Barge traffic	377,580	348,940	275,673	257,560
Total	2,595,585	2,778,108	3,060,516	2,942,393

Water-supply.—The water-supply is controlled by the corporation. The works at Longdendale, begun in 1848, were completed, with extensions in 1884, at a cost of £3,147,893. The area supplied by Manchester waterworks was about 85 square miles, inhabited by a million people. The increase of trade and population led to the obtaining of a further supply from Lake Thirlmere, at the foot of Helvellyn and 96 miles from Manchester. The watershed is about 11,000 acres. The engineering difficulties of the alteration of the level of the lake and the conveyance of the water so great a distance were skillfully overcome. The daily consumption is over 32 million gallons. Manchester supplies in bulk many local authorities in the district between Thirlmere and the city. The Manchester corporation have also established works for the supply of hydraulic power for various trade purposes.

Lighting.—The gas lighting of Manchester has been in the hands of the corporation for many years. Salford has separate gasworks, also under municipal control. It is possible that the value and excellence of the gasworks may have retarded the introduction of the electric light. Powers were sought in 1882; but differences arose between the corporation and the Board of Trade, and a provisional order was not obtained until 1890. Electricity works have been erected, the light is supplied in the central area of the city, and large extensions are in progress for the remainder of Manchester and the adjoining urban districts.

Sanitary Condition.—Although continuous efforts have been made, and the social condition of the mass of the people has very greatly improved, Manchester and Salford have high death-rates. Dr John Tatham has constructed a Manchester life-table based on the vital statistics of the decennium 1881-90; and from this it appears that while in England and Wales of 1000 men aged 25 nearly 800 survive to be 45, and of 1000 aged 45, 569 survive to be 65, in the city of Manchester the survivors are only 732 and 414 respectively. The expectation of life, at 25, is for England and Wales 36.12 years, and for Manchester 30.69 years. The city death-rate in 1891 was 26.0 per thousand living; in 1894 it was 19.8; in 1898, 21.2. For the 10 years ending 1900 the average death-rate was 23.4, that of Salford 24.1. The reports of the medical officers show that whilst the density of the population, the impurity of the atmosphere, and the pollution of the streams are difficult elements in the sanitary problem, great efforts have been made towards improving the health of the people.

Churches.—Manchester Cathedral, which was built as a parish and collegiate church and dates from the 15th century, with traces of much older work, has been extensively restored, under Mr Champneys. The old churchyard has again been encroached upon to allow of the widening of Victoria Street. A new porch has been built in harmony with the rest of the structure. The Gordon memorial window and the recumbent statues of Bishop Fraser and Mr Hugh Birley, M.P., should be named. In 1847 Manchester was created a bishopric. The wardens and fellows were converted into deans and

canons, and the parish church became the cathedral. The first bishop, James Prince Lee, died in 1870; the second, James Fraser, died in 1885. He was succeeded by Dr James Moorhouse, formerly bishop of Melbourne. Including the cathedral, there are more than 100 Anglican churches in Manchester and Salford. Salford is a Roman Catholic see. With Salford Cathedral there are, in the two boroughs, about 40 places of worship belonging to the Church of Rome. The other religious denominations include the Armenian Church, Baptist, Bible Christian, Catholic Apostolic Church, Christadelphian Ecclesia, United Friends, Congregationalists, German Protestant, Greek, Independent Methodists, Jews, Labour Church, Methodist New Connection, New Jerusalem Church, Presbyterians, Primitive Methodist, Salvation Army, Society of Friends, Unitarians, United Methodist Free Church, Welsh Calvinistic Methodists, and Wesleyan Methodists. The Secularists and the Positivists have also congregations.

Philanthropic Institutions.—In addition to the Royal Infirmary, the Salford Hospital, St Mary's Hospital, and other institutions of that type, mention may be made of the Boys' and Girls' Refuges, and the Charter Street Ragged School and Working Girls' Home—both of which are large and important.

Literature, Science, and Art.—Numerous societies and institutions exist for the cultivation of learning. The Literary and Philosophical Society is one of the oldest in the kingdom, and has a high reputation. The Lancashire and Chester Antiquarian Society, the Record Society, and the Chetham Society, have their headquarters in the city. There are nine daily papers, and many weekly papers and periodicals. The *Manchester Quarterly* is issued by the Manchester Literary Club. The success of the Art Treasures Exhibition in 1857 was repeated in the Jubilee Exhibition of 1887. In 165 days there were 4,765,137 admissions. The Manchester Academy of Fine Arts is a society of artists, and holds an annual exhibition in the city art gallery.

University and Schools.—The educational arrangements of the city are on an extensive scale. There are 74 board schools, 55 belonging to the Church of England, 25 Roman Catholic, 5 British, and 5 Wesleyan. In Salford there are 24 board schools, 1 British, 29 Church of England, 11 Roman Catholic, and 3 Wesleyan. The Moss Side School Board has two schools. The two corporations have taken an active interest in secondary education. The Manchester Municipal School of Technology is large and well equipped. The School of Art forms one department, and in connexion with this there is an Arts and Crafts Museum. The Salford Technical School adjoins Peel Park, and is a handsome building, erected at a cost of £84,000. The Manchester Grammar School, founded in 1515, has earned a high reputation. It is connected by scholarships with Oxford University and the Victoria University. The foundation of William Hulme maintains a grammar school at Alexandra Park. There are also four high schools for girls. The Victoria University received its charter in 1880, and in 1883 a supplementary charter conferring the power of granting degrees in medicine as well as in science and arts. Owens College, which was at first the only one in the university, has since been joined by University College, Liverpool, and the Yorkshire College of Science, Leeds. A new educational type—that of a federal teaching university—was thus created; but in consequence of the application of Liverpool for a separate charter, there is a probability that the Victoria University will develop into three civic universities of Manchester, Liverpool, and Leeds. The original endowment of Owens College, founded under the bequest of John Owens, was about £100,000, but this has been greatly increased by other benefactors. Mr Thomas Ashton's gifts are estimated at £80,000. Dr Richard Copley Christie, formerly a professor, gave the building known as the Christie Library, which cost £21,000, and devoted £50,000 of the funds at his disposal as a legatee of Sir Joseph Whitworth to the erection of the Whitworth Hall. These, with the building containing the Manchester Museum (an admirably arranged collection illustrating geology, biology, and anthropology), complete the quadrangle of the main college buildings. There are various large denominational colleges in the district, and many of those preparing for the ministry receive their arts training at Owens College. The Royal College of Music is another educational institution which should not be overlooked. The various authorities have a working agreement for the co-ordination of the educational work of the district.

Libraries and Museums.—The district has many libraries. Chetham's Hospital contains a blue-coat school for 100 boys and a public library. The Salford Museum and Library was founded in 1849. This includes reference library, 5 lending libraries, and 2 reading-rooms. The central building contains also the museum and art gallery. The Manchester Free Library was opened in 1852. There is now a large reference library, containing probably the best working collection of books in the North of England, 13 lending libraries, and 5 reading-rooms. The stock of books amounts to 292,000. By the generosity of Mrs Enriqueta Rylands the city received in 1899 an endowed library of a remarkable character—the John Rylands Library, which has been erected by his widow to

the memory of a well-known Manchester worthy. The building is a noble and beautiful structure, and the library is large and important. It includes the famous Althorp collection, which was bought from Earl Spencer and incorporated by Mrs Rylands into her scheme. The regulations for use of the Rylands Library are similar to those in force at the British Museum. Moss Side, which is in the parliamentary limits, but has its own urban council, has a municipal library, and also a small park and recreation ground.

Recreation.—The recreation of the population is provided for in many ways. There are eleven theatres, mostly large in size. The concerts of classical music and other musical entertainments have more than local celebrity. The Bellevue Zoological Gardens is a favourite holiday place for working people. The Ancots Recreation Committee have since 1882 had Sunday lectures, and occasional exhibitions of pictures, window gardening, &c. The Ancots Art Museum was founded to carry out the educational influences of art and culture generally. In addition to works of art, there are concerts, lectures, reading circles, &c. The museum is worked in connexion with a university settlement.

Manufactures and Commerce.—Manchester, whilst the centre of the cotton industry, is also the seat of large engineering and chemical trades. The central area is more and more occupied by offices and warehouses, and the works and factories are grouped outside. This process has been carried out so largely that the real Manchester is difficult of definition. From one point of view the whole of south-east Lancashire, and some portions even of Cheshire and Derbyshire, may be regarded as one vast urban district, having many interests and characteristics in common, although split up into separate areas of local government. The annual value of the city of Manchester increased from £2,943,545 in 1896 to £3,394,879 in 1901; that of Salford from £835,455 to £967,727. In the districts where there was more room for expansion the increase is also striking. Thus the annual value of Stretford has risen from £143,956 to £194,366 within the years named; the corresponding figures for similar urban districts adjoining Manchester are equally demonstrative of the increase of trade and population. The amount passing through the Manchester bankers' clearing-house in 1890 was £162,849,544; in 1899, £222,563,348; in 1900, £247,206,000; in 1901, £235,487,000. Manchester is the headquarters of the Wholesale Co-operative Society.

Municipality.—Manchester received a municipal charter in 1838, received the title of city in 1853, and became a county borough in 1889. The city is divided into 25 wards, and the corporation consists of 26 aldermen and 78 councillors. The mayor received the title of Lord Mayor in 1893. The municipal charter of Salford was granted in 1844. There are 16 wards. Sixteen aldermen and 48 councillors constitute the Town Council. Salford became a county borough in 1889.

By the Reform Bill of 1832 Manchester received two and Salford one representative. In 1868 this was increased to three for Manchester (each voter, however, having only two votes) and two for Salford. At present Manchester sends six and Salford three members to the House of Commons.

Manchester, a township of Hartford county, Connecticut, U.S.A., north-east of the centre of the state, a few miles east of Hartford, containing an area of 21 square miles and including the villages of Manchester, South Manchester, Manchester Green, and Buckland. Its manufactories include silk, paper, cotton, and needle mills, and factories of electric machinery and appliances. The total capital invested in manufacturing in 1900 was \$7,330,806, and the various establishments employed 3118 wage-earners, and had products valued at \$5,939,943. Population (1890), 8222; (1900), 10,601, of whom 3771 were foreign-born.

Manchester, a city of New Hampshire, U.S.A., capital of Hillsboro county. It is on the Merrimac river, at Amoskeag Falls, which furnish water-power for its manufactures. Its manufacturing establishments had in 1900 a capital of \$22,426,125, employed an average number of 19,032 wage-earners, and produced goods valued at

\$26,607,600. Of this total product, cotton goods were valued at \$11,723,508, boots and shoes at \$4,052,204, hosiery and knitted goods at \$834,343, and foundry and machine-shop products at \$511,208. Manchester is the seat of St Anselm's College, a Roman Catholic institution founded in 1893. In 1899 this had 19 instructors, and was attended by 61 students. The assessed valuation of real and personal property in 1900, on a basis of about 70 per cent. of the full value, was \$32,706,794, the net debt of the city \$1,627,025, and the rate of taxation \$19.50 per \$1000. Population (1890), 44,126; (1900), 56,987, of whom 24,257 were foreign-born and only 28 were negroes. The death-rate in 1900 was 19.2, the same as in 1890.

Manchester, a city of Virginia, U.S.A., on the south bank of the James river, opposite Richmond, with which it is connected by bridges. Though within the limits of Chesterfield county, it is independent of county government. It is on the Atlantic Coast Line, the Seaboard Air Line, and the Southern railways. It is a manufacturing city of some importance, using the water-power from the falls of James river at this point. Population (1880), 5729; (1890), 9246; (1900), 9715, of whom 138 were foreign-born and 3338 were negroes.

Manchuria.—The three provinces of China lying outside the Great Wall, generically known as Manchuria, were described in the earlier volumes (xv. 465) of this Encyclopædia (ninth edition). Since 1883 the country has made considerable progress. Immigrants from the older and over-populated parts of China have been flocking thither in great numbers, and much new land has been brought under cultivation. The general progress is exemplified in the returns of trade passing through the treaty-port of Newchwang. The total value of the trade in 1880 was H. taels 6,725,000, and in 1899 it had risen to H. taels 48,357,000; but in 1900, owing to the disturbed state of the country, it fell to £1,023,260, or H. taels 38,116,450. The population is estimated as follows for each of the three divisions:—

Province of Shengking (Feng Tien)	4,000,000
" " Kirin	6,500,000
" " Hei lung chiang	2,000,000
Total	12,500,000

The original population was entirely Manchu, but they are rapidly being elbowed out by the more industrious Chinese. Their number is estimated at from 2 to 3 millions, or about 25 per cent. of the whole population. Nearly all of them are officials or hangers-on at the various civil and military establishments, and but for the official support they receive in the shape of pay or perquisites, they would rapidly be squeezed out. Gold mines are worked at several places in the northern part of Manchuria, of which the principal are on the Muho river, an affluent of the Amur, and near the Russian frontier. Mines are also worked at Kwanyin-shan, opposite the Russian frontier town of Radevska, and at Chia-pi-kon, on an affluent of the upper Sungari. Manchuria has been claimed by Russia as her particular sphere of interest, and in the course of the disturbances of 1900, Russian troops occupied various parts of the country (see CHINA). Eventually a Manchurian Convention was arranged between China and Russia, by which Russia was to evacuate the province; but various difficulties arose, and no actual ratification of this convention had been made by Russia up to June 1902. The Anglo-German agreement of October 1900, to which Japan also became a party, and by which it was agreed to "maintain undiminished the territorial condition of the Chinese empire," was considered by Great Britain and Japan not to exclude Manchuria; but Germany, on the

other hand, declared that Manchuria was of no interest to her. The Anglo-Japanese treaty of 1902, however, was ostensibly directed towards the preservation of Manchuria in Chinese hands. Railways are in course of construction by Russian capital from Port Arthur northwards *via* Mukden, to connect with the Siberian main line to Vladivostok. British capital has been invested in the extension of the Chinese Northern railway to Newchwang, and the fact was officially recognized by an agreement between Great Britain and Russia in 1899.

Vide Blue Book, *China*, No. 2 (1899), and "Report on Manchuria," by Colonel Browne, military attaché, Blue Book, *China*, No. 1 (1899).

Mancini, Pasquale Stanislao (1817–1888), Italian jurist and statesman, was born at Castel Baronia, in the province of Avellino, on 17th March 1817. At Naples, where he studied law and displayed great literary activity, he rapidly acquired a prominent position, and in 1848 was instrumental in persuading Ferdinand II. to participate in the war against Austria. Twice he declined the offer of a portfolio in the Neapolitan Cabinet, and, upon the triumph of the reactionary party, undertook the defence of the Liberal political prisoners. Threatened with imprisonment in his turn, he fled to Piedmont, where he obtained a university professorship and became preceptor of the Crown Prince Humbert. In 1860 he prepared the legislative unification of Italy, opposed the idea of an alliance between Piedmont and Naples, and, after the fall of the Bourbons, was sent to Naples as administrator of justice, in which capacity he suppressed the religious orders, revoked the Concordat, proclaimed the right of the State to Church property, and unified civil and commercial jurisprudence. In 1862 he became Minister of Public Instruction in the Rattazzi Cabinet, and induced the Chamber to abolish capital punishment. Thereafter, for fourteen years, he devoted himself chiefly to questions of international law and arbitration, but in 1876, upon the advent of the Left to power, became Minister of Justice in the Depretis Cabinet. His pronounced Liberal tendencies found expression in the extension of press freedom, the repeal of imprisonment for debt, and the abolition of ecclesiastical tithes. During the Conclave of 1878 he succeeded, by negotiations with Cardinal Pecci (afterwards Leo XIII.), in inducing the Sacred College to remain in Rome, and, after the election of the new pope, arranged for his temporary absence from the Vatican for the purpose of settling private business. Resigning office in March 1878, he resumed the practice of law, and secured the annulment of Garibaldi's marriage. The fall of Cairoli, in consequence of the occupation of Tunis by France in 1881, led to Mancini's appointment to the Foreign Office (April 1881), where he conducted the negotiations for and concluded the Triple Alliance, and promoted a closer understanding between Italy and Great Britain, although, partly through lack of military preparation, he declined to join in the British expedition to Egypt. In 1885, however, he undertook an expedition to Massawa with the consent of Great Britain, and thus inaugurated Italian colonial policy. During the cholera epidemic of 1885 he accompanied King Humbert to Naples, and displayed great courage and activity in organizing measures of relief. In June 1885 he was succeeded at the Foreign Office by Count di Robilant, and died at Rome on 26th December 1888. A man of extraordinary versatility and of facile though verbose eloquence, Mancini possessed for many years considerable ascendancy over the Italian Chamber, and, while not a great statesman, left an indelible mark upon the history of his country.

(H. W. S.)

Mandalay, formerly the capital of independent Burma (*q.v.*), now the headquarters of the Mandalay division and district, as well as the chief town in Upper Burma. The DIVISION includes the districts of Mandalay, Bhamo, Myit Kyina, Katha, and Ruby Mines, with a total area of 25,767 square miles, and a population (1891) of 641,466, (1901), 778,255, giving an average density of 30 inhabitants to the square mile. There were 2950 towns and villages in 1898–99, and the revenue paid was Rs.16,52,036. The Mandalay DISTRICT has an area of 2071 square miles, and a population (1891) of 375,055, (1901) 367,230, showing a density of 177 inhabitants to the square mile. It is divided into five subdivisions, with seven townships and 786 villages. About 600 square miles of the district along the Irrawaddy river are flat land, nearly all cultivated. To the north and east of the district there are some 1500 square miles of high hills and tablelands, forming geographically a portion of the Shan tableland. Here the fall to the plains averages 3000 to 4000 feet in a distance of 10 miles. This part of the district is well wooded and watered. The rainfall in the plain is scanty. The Maymyo subdivision has very fine plateaus of 3000 to 3600 feet in height. The highest peaks are between 4000 and 5000 feet above sea-level. The Irrawaddy, the Myit-ngè, and the Madaya are the chief rivers. The two last come from the Shan States, and are navigable for between 20 and 30 miles. There are many canals in the district, most of which have fallen greatly into disrepair, and the Aungbinle, Nanda, and Shwepyik lakes also supply water for cultivation. A systematic irrigation scheme is being carried out by Government. The Sagyin hills near Madaya are noted for their alabaster, and rubies are also found, but in no great quantity. There are 285½ square miles of forest reserve in the district, but there is little teak, and its quality is not great. The tracts are chiefly reserved for bamboos and the ordinary kinds of timber. The climate of the district is dry and healthy. During May and June and till August strong winds prevail. The thermometer rises to about 107° in the shade in the hot weather, and the minimum in the month of December is about 55°. The rainfall is small, the average being under 30 inches (23·77 in 1898–99). Epidemics are rare.

MANDALAY TOWN stands on the left bank of the Irrawaddy, in 21° 58' N. and 96° 8' E. Its height above mean sea-level is 315 feet. Its area is—town, 18·51 square miles, cantonment, 6·14 square miles; total, 24·65. Mandalay is quite a modern town, and was built in 1856–57 by King Mindon. It is now divided into the municipal area and the cantonment. The town covers an area of six miles from north to south and three from east to west, and has well-metalled roads lined with avenues of trees and regularly lighted and watered. The cantonment consists of the area inside the old city walls, and is now called Fort Dufferin. In the centre stands the palace, a group of wooden buildings, many of them highly carved and gilt, resting on a brick platform 900 feet by 500 feet, and 6 feet high. The greater part of it is now utilized for military and other offices. The garrison consists of one regiment of British infantry, one British mountain battery, and two regiments of native infantry. There are many fine pagodas and monastic buildings in the town. The population was 188,815 in 1891, and 182,498 in 1901, showing a decrease of 3·36 per cent. The population is very mixed. Besides Burmese there are Zerbadis (Burman Mahomedans, the offspring of a Mahomedan with a Burman wife), Mahomedans, Hindus, Suratis, Jews, Chinese, Shans, and Manipuris, called Kathes Kachins and Palaungs. The chief classes in the district in 1891 were Buddhists and Jains, 343,376; Mahomedans, 18,693; Hindus, 9613; and native Christians, 2230. Trains run from Mandalay to Rangoon, Myit Kyina, and up the Mandalay–Kunlong railway, now in part open. The steamers of the Irrawaddy Flotilla Company also ply in all directions. The chief public buildings are the court-house, the courts of the commissioner and judicial commissioner, telegraph office, post office and general hospital. There are twenty bazaars, the chief of which, the Zegyo, was burnt in 1897, but is rebuilt.

(J. G. Sc.)

Mandaue, a town on the eastern coast of the island of Cebu, Philippine Islands, in 10° 26' N. Its climate is very hot, but healthful. The principal occupation of its inhabitants is rice-culture. Cebu-Visayan is the language. Population, 15,000.

Mandi, a native state of India, within the Punjab. It ranks as the most important of the hill states to which British influence extended in 1846 after the first Sikh war. The territory lies among the lower ranges of the Himalaya, between Kangra and Kulu.

Area, 1131 square miles; population (1881), 147,017; (1891), 163,923; (1901), 174,045; average density, 158 persons per square mile; estimated gross revenue, Rs.4,30,000; tribute, Rs.1,00,000; military force, 691 men. The chief, whose title is raja, is a Rajput of old family. Owing to infirmity, he is assisted in administration by a British official. Considerable sums have been expended on roads and bridges. An important product of the state is salt, which is mined in two places. The British Government manages the mines, and pays to the raja 13 annas on every maund of salt sold, which yielded him Rs.1,01,264 in 1897-98. The town of MANDI is on the left bank of the Beas, which is here a mountain torrent, 2991 feet above the sea. Population about 5000.

Mandla, a town and district of British India, in the Jubbulpore division of the Central Provinces. The town is on the river Nerbudda, 1787 feet above the sea. Population (1881), 4732; (1891), 5057.

The district of MANDLA, among the Satpura hills, has an area of 5056 square miles; population (1881), 301,760; (1891), 339,373; (1901), 297,454, showing an increase of 12 per cent. between 1881 and 1891, and a decrease of 12.35 per cent. between 1891 and 1901; average density, 58 persons per square mile; land revenue, Rs.1,46,000, being little more than one anna per acre; cultivated area (1897-98), 446,923 acres, of which only 1078 were irrigated; number of police, 315; boys at school (1896-97), 2290, being 8.6 per cent. of the male population of school-going age, the lowest rate in the province; registered death-rate (1897), 96.24 per thousand, showing the results of the famine. The principal crops are rice, wheat, other food grains, pulse, and oil-seeds. There is a little manufacture of country cloth. There is no railway, and few roads. The district suffered most severely from the famine of 1896-97, partly owing to its inaccessibility, and partly from the shy habits of the aboriginal tribes. For an interesting account of the special difficulties of famine relief in Mandla see Appendix to the *Report on the Famine in the Central Provinces* (Nagpur, 1898). The famine of 1900 was scarcely felt.

Mandsaur, or MANDESUR, a town of India, in the native state of Gwalior, on the Rajputana railway, 31 miles south of Neemuch. Population (1881), 22,596; (1891), 27,785. It gave its name to the treaty with Holkar, which concluded the Maratha-Pindari war in 1818. It is now a centre of the Malwa opium trade. In 1897-98 the exports of opium amounted to 4574 chests, paying a duty of Rs.25,32,400. It has a school and dispensary.

Mandvi, a seaport of India, in the native state of Cutch, within the Gujarat province of Bombay, 36 miles from Bhuj, and 182 miles by sea from Karachi. Population (1881), 35,980; (1891), 38,155. It is a weekly port of call for steamers of the British India line, though vessels of 70 tons cannot come any nearer than 500 yards. The pilots and sailors of Mandvi have a high reputation.

Manet, Édouard (1832-1883), French painter, who is regarded as the most important master of the Impressionist school (*q.v.*), was born in Paris in 1832. After spending some time under the tuition of the Abbé Poilou, he entered the Collège Rollin, where his passion for drawing led him to neglect all his other lessons. His studies finished in 1848, he was placed on board the ship *Guadeloupe*, voyaging to Rio de Janeiro, and during the passage never ceased sketching everything he saw. On his return he first studied in Couture's studio (1851), where his independence often infuriated his master. For six years he was an intermittent visitor to the studio, constantly taking leave to travel, and going first to Cassel,

Dresden, Vienna, and Munich, and afterwards to Florence, Rome, and Venice, where he made some stay. Some important drawings date from this period, and one picture, "A Nymph Surprised." Then, after imitating Couture, more or less, in "The Absinthe-drinker" (1866), and Courbet in "The Old Musician," he devoted himself almost exclusively to the study of the Spanish masters in the Louvre. A group was already gathering round him—Whistler, Legros, and Fantin-Latour haunted his studio in the Rue Guyot. His "Spaniard playing the Guitar," in the Salon of 1861, roused much animadversion. Delacroix alone defended Manet, but, this notwithstanding, his "Fifer of the Guard" and "Breakfast on the Grass" were refused by the jury. Then the "Exhibition of the Rejected" was opened, and round Manet a group was formed, including Bracquemond, Legros, Jongkind, Whistler, Harpignies, and Fantin-Latour, the writers Zola, Duranty, and Duret, and Astruc the sculptor. In 1863, when an amateur, M. Martinet, lent an exhibition-room to Manet, the painter exhibited fourteen pictures; and then, in 1864, contributed again to the Salon "The Angels at the Tomb" and "A Bull-fight." Of this picture he afterwards kept nothing but the toreador in the foreground, and it is now known as "The Dead Man." In 1865 he sent to the Salon "Christ reviled by the Soldiers" and the famous "Olympia," which was hailed with mockery and laughter. It represents a nude woman reclining on a couch, behind which is seen the head of a negress who carries a bunch of flowers. A black cat at her feet emphasizes the whiteness of the sheet on which the woman lies. This work is now in the Luxembourg, to which it was presented by a subscription started by Claude Monet (1890). It was hung in 1897 among the Caillebotte collection, which includes the "Balcony," and a study of a female head called "Angelina." This production, of a highly independent individuality, secured Manet's exclusion from the Salon of 1866, so that he determined to exhibit his pictures in a place apart during the Great Exhibition of 1867. In a large gallery in the Avenue de l'Alma, half of which was occupied by Courbet, he hung no fewer than fifty paintings, and among them, besides the works already mentioned, "The Child with a Sword," "A Matador," "Lola of Valence" (from a poem by Baudelaire), "A Monk at Prayer," "A Spanish Dance," "A Vase of Flowers," "Views of the Sea," "A Young Woman in a Spanish Costume" reclining, and many others now scattered through public and private galleries. Only one important picture was absent, "The Execution of the Emperor Maximilian"; its exhibition was prohibited by the authorities. From that time, in spite of the fierce hostility of some adversaries, Manet's energy and that of his supporters began to gain the day. His "Young Girl" (Salon of 1868) was justly appreciated, as well as the portrait of Lola; but the "Balcony" and the "Breakfast" (1869) were as severely handled as the "Olympia" had been. In 1870 he exhibited "The Music Lesson" and a portrait of Mlle E. Gonzales. Not long before the Franco-Prussian war, Manet, finding himself in the country with a friend, for the first time discovered the true value of open air to the effects of painting in his picture "The Garden," which gave rise to the "open air" or *plein air* school. After fighting as a gunner, he returned to his family in the Pyrenees, where he painted "The Battle of the Kearsarge and the Alabama." His pictures were now bought by collectors—M.M. Duret, Gérard, Faure, Hecht, Ephrussi, and De Bellio. His "Bon Bock" (1873) created a *furor*. But in 1875, as in 1869, there was a fresh outburst of abuse, this time of the "Railroad," "Polichinelle," and "Argenteuil," and the jury excluded the artist, who for the second time arranged an exhibition in his

studio. In 1877 his "Hamlet" was admitted to the Salon, but "Nana" was rejected. The following works were exhibited at the Salon of 1881: "In the Conservatory," "In a Boat," and the portraits of Rochefort and Proust; and the Cross of the Legion of Honour was conferred on the painter on 31st December in that year. Manet died in Paris on 30th April 1883. He left, besides his pictures, a number of pastels and engravings. He illustrated *Les Chats* by Champfleury, and Edgar Allan Poe's *Raven*.

Mangaldan, a town in the northern portion of the province of Pangasinan, Luzon, Philippine Islands, about two miles from the shore of the Gulf of Lingayen. Most of its inhabitants are engaged in rice-culture, for which the low and fertile fields in its vicinity are especially adapted. The principal language is Pangasinan; Ilocao is also spoken. Population, 16,000.

Mangaldas Nathoobhai, Sir (1832-1890), Seth or head of the Kapole Bania section of Bombay, a caste of Hindus well known for their thrift and keen commercial instincts, was born on the 15th of October 1832 of a family whose ancestors emigrated from the island of Diu to Bombay soon after the town came into British possession. His grandfather, Ramdas Manoredas, amassed a considerable fortune, which, owing to the premature death of his father, came into the sole possession of Mangaldas at the age of eleven. He had consequently to take charge of the business in early life, though he gave some of his time to English studies under a private tutor. He was married at sixteen to Sethanee Rukminbai, and had three sons and two daughters. After a happy wedded life of sixteen years, his wife died, when Mangaldas established a dispensary at Kalyan in her memory at a cost of about Rs.70,000, and built a special female ward in connexion with the David Sassoon Hospital in Poona at a heavy cost. As a merchant Mangaldas was upright and successful. In social matters he stood forth as a reformer, and to him the change to election from hereditary succession to the headship of the caste is due. In the turmoil caused by the attacks of Karsondas Mulji (*q.v.*) on the proceedings of the Vallabhacharyan maharajas, Mangaldas was his firm supporter. From early years he espoused the cause of education. In 1862 he founded a fellowship in Bombay University to allow graduates to spend some years in Europe. A bequest in his will of a great sum enabled the University to establish seven other similar scholarships. He took keen interest in learning, and in such institutions as the Asiatic and Geographical Societies. In 1866 he was nominated to the Legislative Council, and sat there till 1874, his industry and independent character being reflected in the debates. When failing health compelled him to retire, the local government expressed "the strong sense it entertained of his attention to business and devotion to the interests of the public." In 1867 he revived the Bombay Association, a native political body, over which he presided for a time. In 1872 he was made C.S.I., and in 1875 the dignity of Knight Bachelor was also conferred on him. On the 25th November 1875 the Prince of Wales, being then in Bombay, honoured with his presence the marriage ceremonies of two of Mangaldas's sons. Besides a large donation to the Irish Famine Fund, Sir Mangaldas is known to have expended Rs.75,00,000 on Indian charities. He died at Bombay on the 9th March 1890. (N. B. W.)

Mangalore, a seaport town of British India, administrative headquarters of the South Kanara district of Madras. Population (1881), 32,099; (1891), 40,922;

(1901), 43,821; municipal income (1897-98), Rs.47,430. The harbour is formed by the backwater of two small rivers. Vessels ride in 24 to 30 feet of water, and load from and unload into lighters. In 1897-98 the total seaborne trade of the district was valued at Rs.1,77,04,146; 79 vessels entered and cleared for foreign trade, with an aggregate burthen of 11,897 tons. The chief exports are coffee, cocoa-nut products, timber, rice, and spices. There is a small shipbuilding industry. In 1897-98, 19 vessels were registered, of an aggregate burthen of 377 tons. It has a large Roman Catholic population, with a European bishop, several churches, a convent, and a college. It is the headquarters of the Basel Lutheran mission, which possesses one of the most active printing-presses in southern India, and has also successfully introduced the industries of weaving and the manufacture of tiles. Two colleges (Government and St Aloysius) had 164 students in 1896-97. Besides, there are four high schools, with 1016 pupils, as well as training schools for masters and mistresses. Five printing-presses issue three vernacular periodicals, and there are four libraries and literary associations.

Mang Lön, a state in the northern Shan states of Burma. It is the chief state of the Vü or Wa tribes, some of whom are head-hunters, and Mang Lön is the only one which in 1901 had submitted to the British Government. The state bestrides the Salween, and extends from about 21° 30' to 23° N., or for 100 miles along the river. Its width varies greatly, from a mile or even less on either side of the river to perhaps 40 miles at its broadest part near Taküt, the capital. It is divided into East and West Mang Lön, the boundary being the Salween. There are no Vü or Wa in West Mang Lön. Shans form the chief population, but there are Palaungs, Chinese, and Yanglam, besides Lahu. The bulk of the population in East Mang Lön is Vü, but there are many Shans and Lahu. Both portions of the state are very hilly, and the only flat land is along the banks of streams in the valleys, and here the Shans are settled. There are, however, prosperous settlements and bazaars at Nawng Hkam and Mông Kao in West Mang Lön. The Vü of the eastern half have long since given up head-hunting, and many profess to be Buddhists. The population does not probably exceed 6000 or 7000, and about 5000 of these are Vü. The capital, Taküt, is perched on a hill-top 6000 feet above sea-level. The Sawbwa is a Vü, and has control over two sub-states, Môt Hai to the north and Maw Hpa to the south.

Manila, the capital and chief port of the Philippine Islands, situated on the west coast of Luzon. Its cathedral is in 14° 35' 31" N. and 120° 58' 03" E. Included within the municipality are Manila proper, sometimes called "Old Manila" or "Intramuros," and the wards or districts known as Binondo, Tondo, Trozo or San José, Santa Cruz, Sampaloc, Quiapo, San Miguel, Ermita, Paco, and Arroceros. The important suburb of Malate, although continuous with Ermita, lies outside the city limits. Manila proper is enclosed by walls which were constructed about 1690 and are in a very perfect state of preservation. The surrounding moat is choked with vegetation. Bronze smooth-bore cannon for centuries crowned the ramparts, but have all been removed. Only a saluting battery remains. At the north-west angle of the wall is situated Fort Santiago, called the Black Hole of Manila, on account of the suffocation of a number of native prisoners in one of its foul dungeons during the revolt which began in 1896. Within the walls are a fine cathedral, the cloisters of the Augustinian, Franciscan, Dominican, and Recollect friars, and of the Jesuits, spacious churches belonging to each of these orders, the mission church of the Capuchins, and a con-

vent and church belonging to the order of Santa Clara; the Ayuntamiento, a fine building formerly occupied by municipal officers, and under American rule the headquarters of the military government; the Intendencia, or treasury building; Saint Thomas University, San José Medical and Pharmaceutical College, and a school for primary and secondary instruction, known as San Juan de Letran, all in charge of the Dominicans; the Ateneo Municipal, a school for primary and secondary instruction, in charge of the Jesuits; a nautical school, in charge of an officer of the United States navy; the so-called College of Santa Isabel, which is a school for girls; a large civil hospital, known as San Juan de Dios; the official residence of the archbishop; the Audiencia, or Supreme Court building; a Government mint, capable of coining 12,000 large coins and 11,000 small coins in a day of six hours; large and well-appointed barracks; several poor hotels, and a considerable number of residences. Business within the walls is confined to a few small shops. The streets are so arranged that one side is always in the shade, and the more important of them are paved. The population of the Intramuros district is estimated at 14,000. Between its walls and the bay runs a fine drive, extending southwards from the monument erected in honour of Simon de Anda on the Passig river, to the Luneta, an oval promenade by the sea, which is crowded with carriages every fine evening. The batteries of heavy modern guns, which formerly lay in front of the city wall and at the southern end of the Luneta, were all removed in 1900. Immediately to the east of the Luneta is an open field, called Bagumbayan, the scene of public executions in Spanish days. To the southward of the Luneta and Bagumbayan are situated Ermita and Malate, the most desirable residential districts, on account of the sandy soil and the cool breezes from the bay. In Ermita there is a fine building belonging to the Jesuits, in which are thoroughly equipped meteorological, seismological, and magnetic observatories, and a normal school. Adjacent to this building is a fairly good astronomical observatory, also owned by the Jesuits.

Paco has a few fine residences, numerous native houses, and a large municipal cemetery, where the dead are buried in niches in two concentric circular walls. The remaining districts of the city are on the north side of the Passig river, which is spanned by three bridges, known respectively as the Bridge of Spain, the Suspension Bridge, and the Ayala Bridge. These structures are inadequate to meet the necessities of the public, and a fourth bridge was begun in 1900. The central span of the Ayala Bridge rests on an island, where are situated an insane asylum and an orphanage. At its southern end is the large new "Germinal" tobacco factory. At the northern end of the suspension bridge is a good cold-storage plant, opened to the public in 1900; at its southern end is the Government ice and cold-storage plant, which is capable of producing 60 tons of ice daily, and has 433,440 cubic feet of cold storage, divided between ten refrigerating rooms for meat, sufficient for 5000 carcasses of beef, 7000 of sheep, and 107 tons of pork, and two rooms for game, fruits, and vegetables. Binondo, on the north bank of the Passig, is the most important district of the city and the centre of its great business interests. Its more important buildings are the post office, the custom-house, the Hotel de Oriente, and "La Insular" tobacco factory. All the large foreign commercial houses and the banks are in Binondo. Two of its streets, the Escolta and the Rosario, are the most important business streets of the city. In the former are situated the best shops, while the latter is lined from end to end with the shops of Chinese merchants. Tondo lies immediately to the north of Binondo. It is a native residential quarter, but has some unimportant shops and "La Rosa" tobacco factory. Many of the houses are of nipa. The greater part of this district was burned over by insurgents on the night of 22nd February 1899, and the most important market in the city was destroyed. In its place has arisen a very large modern fireproof structure of iron and cement. Tondo church is one of the most conspicuous buildings in the city. In this district are the only cotton-mills in the Philippines and the Manila station of the only railway. Santa Cruz and Quiapo are occupied chiefly by the residences and shops of the middle class. There

is a large tobacco factory in the latter district. One of the finest churches in the city is situated in San Sebastian; also a large distillery. In San Miguel many of the finest residences are to be found, including the palace of the governor-general. The only brewery in the Philippines is in this district. In Trozo are situated a large gaol and penitentiary and the leper hospital, San Lazaro.

The ground on which Manila is built is flat, and at no point rises more than 15 feet above water-level at high tide. As a consequence, whole districts are often flooded during typhoons. Esteros, or creeks, connecting with the river, ramify through the city in various directions, and when improved will afford a valuable means of transportation. They have always been used to a considerable extent by small native craft. Only a few of the principal streets are paved, but many others have been macadamized since the American occupation. The city has good waterworks, and is well lighted by electricity. Under American administration it has been thoroughly cleaned; two crematories for the destruction of garbage have been erected, and a third begun. No rapid transit facilities exist. There are two short tram lines, on which small cars are drawn by native ponies, the service thus afforded being wretchedly inadequate. There are six theatres, in two of which European companies sometimes appear. With the exception of the churches, no high buildings have been constructed in Manila, on account of danger from earthquakes. The better residences have a lower story of stone or brick and a second story of wood, with roof of tiles or corrugated iron. Window-glass is little used, its place being taken by thin squares of oyster shell set in sliding wooden frames. Lower-story windows are barred with iron. Small steamers engaged in the coasting trade can enter the Passig river, but large vessels are forced to lie in the bay, which is too large to afford them any protection. Under Spanish administration, millions of dollars were expended on two breakwaters designed to cut off an extensive basin from the bay immediately south of the mouth of the river. The completion of these breakwaters and the dredging of the basin thus formed will give excellent harbour facilities. A million dollars in gold were appropriated by the United States in September 1900 for the carrying out of this work. The relative commercial importance of Manila, as compared with other ports of entry in the Philippines, is set forth in the following table of entrances and clearances of vessels for the year ending 30th June 1900:—

Foreign Trade.

	Entered.	Tonnage.	Cleared.	Tonnage.
Manila	412	541,158	348	511,522
All other entry ports .	154	125,155	153	130,453

Coastwise Trade.

	Entered.	Tonnage.	Cleared.	Tonnage.
Manila	1280	241,193	1310	255,004
All other entry ports .	2066	217,882	2356	225,998

The volume of trade is increasing rapidly. The largest receipts from customs under Spanish sovereignty were \$5,888,330 in 1897. For the fiscal year ending 30th June 1899 the receipts were \$9,770,431. The population of Manila is estimated at 250,000 souls, of whom about 50,000 are Chinese. (d. c. w.)

Maning, Frederick Edward (1812–1883), New Zealand judge and author, son of Frederick Maning, of Johnville, county Dublin, was born on the 5th of July 1812. His father emigrated to Tasmania in the ship

Ardent in 1824, and took up a grant of land there. Young Maning served in the fatuous expedition which attempted to drive in the Tasmanian blacks by sweeping with an unbroken line of armed men across the island. Soon afterwards he decided to try the life of a trader among the wild tribes of New Zealand, and, landing in the beautiful inlet of Hokianga in 1833, took up his abode among the Ngapuhi. With them the tall Irish lad—he stood 6 feet 3 inches—full of daring and good-humour, and as fond of fun as of fighting, quickly became a prime favourite, was adopted into the tribe, married a chief's daughter, and became a "Pakeha-Maori" (foreigner turned Maori). With the profits of his trading he bought a farm of 200 acres on the Hokianga, for which, unlike most white adventurers of the time, he paid full value. When New Zealand was peacefully annexed in 1840, Maning's advice to the Maori was against the arrangement, but from the moment of annexation he became a loyal friend to the Government, and in the wars of 1845-46 his influence was exerted with effect in the settlers' favour. Again, in 1860, he persuaded the Ngapuhi to volunteer to put down the insurrection in Taranaki. Finally, at the end of 1865, he entered the public service as a judge of the Native Lands Court, where his unequalled knowledge of the Maori language, customs, traditions, and prejudices was of solid value. In this office he served until 1881, when ill-health drove him to resign, and, two years later, to seek surgical aid in London, where, however, he died of cancer on the 25th of July 1883. At his wish, his body was taken back to New Zealand and buried there. A bust of him is placed in the public library at Auckland. Maning is chiefly remembered as the author of two short books, *Old New Zealand*, and *History of the War in the North of New Zealand against the Chief Heké*. Both books were reprinted in London in 1876 and 1884, with an introduction by the earl of Pembroke. The former, written in an easy, gossipy style, embodies recollections of the days of tribal warfare, trading in heads, cannibalism, and anarchy, and as a sketch of Maori life and manners it is unrivalled, and must remain so. The story of Heké's war is dramatically put into the mouth of a Maori chief who took part in it, and shows an extraordinary grasp of the native mind and point of view. Maning, who was an excellent *raconteur*, and had a well-stored memory, wrote little else; but some of his judgments in native land disputes are of real historical interest, containing much more than dry technical expositions of tribal land titles.

(W. P. R.)

Manipur, a native state on the north-east frontier of India, in political subordination to the chief commissioner of Assam. Estimated area, 8000 square miles; estimated population (1881), 221,070; (1901), 283,957. The records of the census of 1891 were destroyed in the disturbances of that year.

The country is called Kasse or Kathe by the Burmese, and the proper name of the capital is Imphal. Disputed successions have always been a cause of trouble. The raja, Chandra Kirti Singh, died in 1886, and was succeeded by his eldest son, Sura Chandra Singh, who appointed his next brother, Kula Chandra Dhuya Singh, *jubraj* or heir apparent. In 1890 another brother, the *senaputti* (or commander-in-chief) Takendrajal Singh, de-throned the raja, and installed the *jubraj* as regent, the ex-raja returning to Calcutta. At the end of February 1891 the chief commissioner of Assam (Mr Quinton) marched to Manipur with 400 Gurkhas, in order to settle the question of succession. His purpose was to recognize the new ruler, but to remove the *senaputti*. After some futile negotiations with a view to the holding of a *darbar*, Mr Quinton sent an ultimatum requiring the surrender of the *senaputti*, by the hands of the political resident, Mr F. Grimwood; but no result followed. An attempt was then made to arrest the *senaputti*, but after some sharp fighting, in which Lieut. Brackenbury was killed, he escaped; and the Manipuris then attacked the British residency with an overwhelming force. Mr Quinton was

compelled to ask for a parley, and he, Colonel Skene, Mr Grimwood, Mr Cossins, and Lieut. Simpson, unarmed, went to the fort to negotiate. They were all there treacherously murdered, and when the news arrived the Gurkhas retreated (25th March) to Cachar, Mrs Grimwood and the wounded being with them. This led to a military expedition, which did not encounter much resistance. The various columns, converging on Manipur, found it deserted; and the regent, *senaputti*, and others were captured during May. After a formal trial, the *senaputti* and one of the generals of the rebellion were hanged, and the regent transported to the Andaman Islands. But it was decided to preserve the existence of the state, and a child of the ruling family, named Chura Chand, of the age of five, was nominated raja. He was sent to be educated in the Mayo College at Ajmere. Meanwhile the administration was conducted under British supervision. In 1897-98 the total revenue was Rs. 3,46,709, of which Rs. 1,94,348 was derived from land and Rs. 97,640 from house tax. The expenditure included Rs. 75,810 for public works, Rs. 58,901 for police, and a tribute of Rs. 50,000 imposed after the rebellion. The police force numbers 338 men. A Gurkha battalion is permanently stationed at Manipur. There are ten schools, with 594 pupils. Three roads are maintained—to Cachar, to Kohima in the Naga Hills, and to Tammu on the Burma frontier. In 1897-98 the total imports were valued at Rs. 1,65,000, chiefly piece goods, mineral oil, betel-nuts, and dried fish. The exports were Rs. 93,000, chiefly cattle, tea-seed, and rice. During five years the rainfall averaged 80-55 inches.

See GRIMWOOD, MRS ETHEL ST CLAIR. *My Three Years in Manipur*. London, 1891.—*Manipur*: compiled from the columns of the *Pioneer*, Allahabad, 1891.

Manisa, the ancient *Magnesia ad Sipylum*, the chief town of the Saru-khán sanjak of the Aidin (Smyrna) vilâyet of Asia Minor, situated in the valley of the Gediz Chai, Hermus, at the foot of Mount Sipylus, and connected by railway with Smyrna, Ala-shehr, and Konia. Manisa is an important commercial centre, and contains interesting buildings dating from the times of the Seljûk and early Osmanli sultans. It is the seat of a flourishing American mission. The population amounts to 38,000 (Moslems 22,000, Christians 15,000, Jews 1000). In 1204 Manisa was occupied by John Ducas, who, when he became emperor, made it the Byzantine seat of government. In 1313 the town was taken by Saru Khán, and in 1398 it submitted to the Osmanli sultan Bayezid I. In 1419 it was the scene of an insurrection, which was crushed by Prince Murad, whose residence in the town as Murad II., after twice abdicating the throne, is one of the most romantic stories in Turkish history. In the 17th century Manisa became the residence of the powerful Dere Bey family, Kara Osman Oghlu.

Manistee, a city of Michigan, U.S.A., capital of Manistee county, on the shore of Lake Michigan, at the mouth of Manistee river, on the west side of the Lower Peninsula, at an altitude of 600 feet. It is irregularly laid out, is divided into seven wards, and has sewerage and water works (the Holly pumping system). It is entered by three railways—the Pere Marquette, the Manistee and Grand Rapids, and the Manistee and North-Eastern. It has extensive salt manufactures from salt springs, and large lumber mills, including saw, shingle, and planing mills. It has also an extensive lake commerce. Population (1890), 12,812; (1900), 14,260, of whom 4966 were foreign-born.

Manitoba, a province of Canada, bounded on the S. by the United States, on the W. by Assiniboia and Saskatchewan, on the N. by Saskatchewan and Keewatin, and on the E. by Keewatin and Ontario. (For the geology, fauna, and flora, see CANADA.) Cold winters and warm summers, with a clear, bracing atmosphere, and small rainfall and snowfall, are the salient features of the climate. The table on the next page gives the normal temperature and precipitation at a number of places:—

	Elevation. Feet.	Average Temperature.		Average Precipitation. Inches.
		Summer.	Winter.	
Winnipeg	764	59-7°	1-5°	20-67
Portage la Prairie	854	61-7°	0-7°	18-84
Brandon	1194	58-4°	0-2°	16-20
Russell	1830	55-8°	-2-4°	18-04
Fort Ellice	850	57-9°	3-5°	16-07
Sourisford	1464	63-8°	2-4°	13-57

Area and Population.—The area covers 73,956 square miles, of which 64,066 are land and 9890 water. The population in 1871 was 18,995; 1881, 62,260; 1891, 152,506; and 1901, 254,947 (138,332 males, 116,615 females). The principal cities and towns are: Winnipeg (42,340), Brandon (5380), Portage la Prairie (3901), St Boniface (2019), West Selkirk (2188), and Morden (1522). In 1901, 49,102 families inhabited 48,415 houses, and the proportion of the urban population to the rural was 27.5 to 72.5. In 1891 there were 34,574 persons engaged in agricultural pursuits; in domestic and personal service, 6712; manufactures and mechanical industries, 5267; professional, 2096; trade and transportation, 6335; non-productive, 932. Classified according to place of birth, the principal nationalities were as follows in 1901:—Canada, 180,853; England, 20,392; Scotland, 8099; Ireland, 4537; other British possessions, 490; Germany, 2291; Iceland, 5403; Austria, 11,570; Russia and Poland, 8854; Scandinavia, 1772; United States, 6922; other countries, 4028. In 1901 the Indians numbered 5827; half-breeds, 10,372.

Government.—The province is under a lieutenant-governor, appointed for a term of five years, with an executive council of five members, responsible to the local legislature, which consists of forty members. It is represented in the Dominion Parliament by four senators and seven members in the House of Commons.

Religion.—Classified according to religion, the various denominations were, in 1901, as follows:—Presbyterians, 65,310; Episcopalians, 44,874; Methodists, 49,909; Roman Catholics, 35,622; Baptists, 9098; Lutherans, 16,473; Mennonites, 15,222; Greek Catholics, 7898; other denominations, 9903; not specified, 638.

Education.—The dual system of education, established in 1871, was abolished in 1890, and the administrative machinery consolidated under one superintendent and a council of public instruction. This act was amended in 1897 to meet the wishes of the Roman Catholic minority, but separate schools were not re-established, nor was the council divided into denominational committees. In 1901 there were 1352 schools with 1669 teachers (618 males and 1151 females); the school population was 63,881, and the number of pupils registered was 51,888; the average attendance was 27,550. There are collegiate institutes for more advanced education at Winnipeg, Brandon, and Portage la Prairie, with a total of 1094 pupils enrolled. There is also a normal school at Winnipeg for the training of teachers. The total receipts during the year were \$1,310,805, Government grant, \$113,452, and municipal taxes, \$753,359; expenditure, \$1,272,617; assets, \$2,440,804; liabilities, \$1,455,420; value of schools, lands, &c., \$1,650,338. There are four denominational colleges and a university for higher education.

Finance.—The principal sources of revenue are the annual subsidy from the Dominion Government, fees for registration of land titles, liquor licences, sale of lands, &c. The chief items of revenue and expenditure for 1901 were as follows:—

Revenue.		Expenditure.	
Dominion Govt. subsidy	\$483,687	Civil government	\$174,748
Land titles office, fees	85,495	Administration of justice	89,252
Provincial lands, sales	120,566	Education	158,998
Asylums, &c.	54,427	Agriculture and immigration	127,459
Interest	36,733	Public works	36,944
Miscellaneous	227,745	Miscellaneous	400,850
	\$1,008,653		\$988,251

The gross debt on 31st December 1901 was \$10,240,488; total assets, \$9,390,384. The Dominion Government debt allowance was \$3,707,190; other assets, not including buildings and land, were \$5,683,188.

Agriculture.—The principal crops are wheat, oats, and barley. The manufacture of butter and cheese is rapidly increasing in importance. The number of beef cattle exported is also increasing, and mixed farming is becoming more general. The following table gives statistics of field crops for the years specified:—

	1883.	1890.	1894.	1901.
	Bushels.	Bushels.	Bushels.	Bushels.
Wheat	5,686,355	14,665,769	17,172,883	50,502,085
Oats	9,478,965	9,513,443	11,907,854	27,796,588
Barley	1,898,430	2,069,415	2,981,716	6,536,155
Flax	No statistics collected.		366,000	266,420
Rye	"	"	59,924	62,261
Peas	"	"	18,434	16,349
Potatoes	"	"	2,035,336	4,797,433
Other roots	"	"	1,841,942	2,925,362

In 1901 there were 2,952,002 acres under crop as follows:—wheat, 2,011,835; oats, 689,951; barley, 191,009; flax, rye, and peas, 24,564; potatoes, 24,429; and other roots, 10,214; average yield of wheat, 25.1 bushels per acre. An experimental farm of 670 acres is supported by the Dominion Government at Brandon; the local government maintains a dairy school, and makes special efforts to encourage the manufacture of cheese and butter.

Fisheries.—The fisheries are all fresh-water, principally white-fish, pickerel, and pike. The total value of the catch—including the adjoining portions of the North-West Territories—in 1900 was \$718,159; the value of vessels, nets, &c., was \$300,980; of exports, \$211,748.

Manufactures.—The following table shows the growth of the manufacturing interests:—

	1881.	1891.
Number of establishments	344	1031
Number of employes	1921	4403
Capital invested	\$1,383,331	\$5,684,237
Wages paid	\$755,507	\$1,905,981
Cost of raw material	\$1,924,821	\$5,688,151
Finished product	\$3,413,026	\$10,155,182

Commerce.—The table below gives statistics of exports, &c., for the period 1874 to 1901, at intervals of five years:—

Year.	Exports.	Imports.	Duty.
1874	\$797,762	\$1,797,033	\$67,472
1879	512,899	1,140,871	274,235
1884	722,730	3,734,573	664,038
1889	782,606	2,191,083	549,458
1894	1,864,964	2,353,768	602,466
1899	2,092,988	5,695,715	1,140,052
1901	1,084,992	5,396,189	1,016,973

Railways.—In 1901 there were 2141 miles of railway in the province, which constituted 11.6 per cent. of the railway mileage of Canada. The principal railways are the Canadian Pacific, Northern Pacific and Manitoba, and Canadian Northern. There was 1 mile of track to 20.9 square miles of area of the province.

(J. W. H.*)

Manitoba, a lake of the province of the same name, (Canada, situated between 50° 11' and 51° 48' N. and 97° 56' and 99° 35' W. It has an area of 1711 square miles, a length of shore-line of 535 miles, and is at an altitude of 810 feet above the sea. It has a total length of 119 miles, a maximum width of 29 miles, discharge of 14,833 cubic feet per second, and an average depth of 12 feet. The Waterhen river, which carries the discharge of Lake Winnipegosis, is the only considerable stream entering the lake. It was discovered by Chevalier de la Verendrye in 1739.

Manitowoc, a city of Wisconsin, U.S.A., capital of Manitowoc county, on the western shore of Lake Michigan, at an altitude of 592 feet. It has a regular plan, is divided into seven wards, and has three railways, the Chicago and North-Western, the Pere Marquette, and the Wisconsin Central. It has a large lake commerce and some manufactures. Population (1890), 7710; (1900), 11,786, of whom 2998 were foreign-born. The death-rate in 1900 was 14.3.

Mankato, a city of Minnesota, U.S.A., capital of Blue Earth county, on the Minnesota river, at its southward bend, in the southern part of the state, at an altitude of 778 feet. It is irregularly laid out, with six wards, and has four railways—the Chicago and North-

Western, the Chicago, Milwaukee and St Paul, the Chicago, St Paul, Minneapolis and Omaha, and the Chicago Great Western. It is in a rich farming region, and has considerable trade and manufactures. Population (1890), 8838; (1900), 10,599, of whom 2578 were foreign-born and 7 were negroes.

Mannheim, a town of Germany, grand-duchy of Baden, on the Rhine, at the confluence of the Neckar, 39 miles by rail north of Carlsruhe. It stands at the head of effective navigation on the Rhine, and is not only the largest port on the upper course of that stream, but the principal emporium for south Germany of such commodities as cereals, coals, petroleum, timber, sugar, and tobacco, with an added large trade in hops, wine, and other south German produce. Owing to the rapid increase in the traffic, it was found necessary to make a new harbour on the other side of the Neckar, which was opened in 1898. The total volume of the trade, by river and rail combined, increased from about 1½ million tons in 1875 to very nearly 9 million tons in 1898. The traffic by the Rhine increased from 6648 vessels of 6,604,800 tons arrived and cleared in 1895 to 12,935 vessels of 9,737,200 tons in 1899; and to this must be added the traffic up and down the Neckar, which also increased from 6243 vessels of 908,300 tons in 1895 to 5556 vessels of 946,100 tons in 1899. In addition to the large harbour opened in 1875, a new commercial harbour was built on the opposite side of the Neckar in the last years of the 19th century, and a third harbour made at Rheinau, three miles above the town. The last was entered by 3408 vessels of 573,130 tons in 1900, as compared with 2404 vessels of 388,621 tons in the preceding year. Mannheim is also the seat of very active and extensive industries, producing especially flour, ironware, machinery, agricultural implements, iron ships, chemicals, oils, cigars, wood-pulp and cellulose articles, carpets, sugar, soap, cement, aniline dyes, furniture, shoes, vehicles, clothing, books, beer, and spirits; it has also several saw and planing mills. A new bridge was thrown across the Neckar in 1890-91. The town has been adorned with a monument to the Emperor William I. (1894) and two fountains (1898) in the palace courtyard, a monument of the war of 1870-71 (1896), and a monument to Bismarck (1900) near the principal railway station. Population (1885), 61,273; (1890), 79,058; (1900), 140,384.

Manning, Henry Edward (1808-1892), English Roman Catholic cardinal, was born at Totteridge, Hertfordshire, on the 15th July 1808,¹ being the third and youngest son of William Manning, a West Indian merchant, who was a director of the Bank of England and governor, 1812-13, and who sat in Parliament for some thirty years, representing in the Tory interest Plympton Earle, Lymington, Evesham, and Penryn consecutively. His mother, Mary, daughter of Henry Leroy Hunter, of Beech Hill, Reading, was of a family said to be of French extraction. Manning's boyhood was mainly spent at Coombe Bank, Sunridge, Kent, where he had for companions Charles and Christopher Wordsworth, afterwards bishops of St Andrews and of Lincoln. He was educated at Harrow, 1822-27, Dr Butler being then the headmaster, but obtained no distinction beyond being in the cricket eleven in 1825. He matriculated at Balliol College, Oxford, in 1827, and soon made his mark as a debater at the Union, where Gladstone succeeded him as president in 1830. At this date he was ambitious of a political career, but his father, having sustained severe losses in business, found

himself no longer in a position to leave his sons free of any necessity to earn their living, and in these circumstances Manning, having graduated in first-class honours in 1830, obtained the year following, through Viscount Goderich, a post as supernumerary clerk in the Colonial Office. This, however, he resigned in 1832, his thoughts having been turned towards a clerical career under Evangelical influences, which affected him deeply throughout life. Returning to Oxford, he was elected a Fellow of Merton College, and was ordained; and in 1833 he was presented to the rectory of Lavington with Graffham in Sussex by Mrs Sargent, whose granddaughter, Caroline, he married on 7th November of that year, the ceremony being performed by the bride's brother-in-law, Samuel Wilberforce, afterwards bishop of Oxford and of Winchester. Manning's married life was of brief duration. His young and beautiful wife was of a consumptive family, and died childless (24th July 1837). The last sadness that thus early overshadowed him tended to facilitate his acceptance of the austere teaching of the Oxford Tracts; and though he was never an acknowledged disciple of Newman's, it was due to the latter's influence that from this date his theology assumed an increasingly High Church character, and his printed sermon on the "Rule of Faith" was taken as a public profession of his alliance with the Tractarians. In 1838 he took a leading part in the Church education movement, by which diocesan boards were established throughout the country; and he wrote an open letter to his bishop in criticism of the recent appointment of the ecclesiastical commission. In December of that year he paid his first visit to Rome, and called on Dr Wiseman in company with Mr Gladstone. In January 1841 Shuttleworth, bishop of Chichester, appointed him archdeacon, whereupon he began a personal visitation of each parish within his district, completing the task in 1843. In 1842 he published a treatise on *The Unity of the Church*, and his reputation as an eloquent and earnest preacher being by this time considerable, he was in the same year appointed select preacher by his University, thus being called upon to fill from time to time the pulpit which Newman, as vicar of St Mary's, was just ceasing to occupy. Four volumes of his sermons appeared between the years 1842 and 1850, and these had reached the 7th, 4th, 3rd, and 2nd editions respectively in 1850, but were not afterwards reprinted. In 1844 his portrait was painted by Richmond, and the same year he published a volume of University sermons, in which, however, was not included the one on the Gunpowder Plot. This sermon had much annoyed Newman and his more advanced disciples, but it was a proof that at that date Manning was loyal to the Church of England as Protestant. Newman's secession in 1845 placed Manning in a position of greater responsibility, as one of the High Church leaders, along with Pusey and Keble and Marriott; but it was with Gladstone and James Hope (afterwards Hope-Scott) that he was at this time most closely associated. In the spring of 1847 he was seriously ill, and that autumn and the following winter he spent abroad, chiefly in Rome, where he saw Newman "wearing the Oratorian habit and dead to the world." He had public and private audiences with the Pope on 9th April and 11th May 1848, but recorded next to nothing in his diary concerning them, though numerous other entries show an eager interest in everything connected with the Roman Church, and private papers also indicate that he recognized at this time grave defects in the Church of England and a mysterious attractiveness in Roman Catholicism, going so far as to question whether he might not one day be a Roman Catholic himself. Returning to England, he protested, but with moderation, against the appointment of Hampden as bishop of Hereford, and continued to take an active

¹ Purcell's assertion that the year of his birth was 1807 rests on no trustworthy evidence.

part in the religious education controversy. Through the influence of Samuel Wilberforce, he was offered the post of sub-almoner to Queen Victoria, always recognized as a stepping-stone to the episcopal bench, and his refusal of it was honourably consonant with all else in his career as an Anglican dignitary, in which he united pastoral diligence with an asceticism that was, at any rate in those days, quite exceptional. In 1850 the decision of the Privy Council, that the bishop of Exeter was bound to institute the Rev. G. C. Gorham to the benefice of Bramford Speke in spite of the latter's acknowledged disbelief in the doctrine of baptismal regeneration, brought to a crisis the position within the Church of England of those who believed in that Church as a legitimate part of the infallible *Ecclesia docens*. Manning made it clear that he regarded the matter as vital, though he did not act on this conviction until no hope remained of the decision being set aside or practically annulled by joint action of the bishops. In July he addressed to his bishop an open letter on "The Appellate Jurisdiction of the Crown in Matters Spiritual," and he also took part in a meeting in London which protested against the decision. In the autumn of this year (1850) was the great popular outcry against the "Papal aggression" (see WISEMAN), and Manning, feeling himself unable to take part in this protest, resigned, early in December, his benefice and his archdeaconry; and writing to Mr Hope-Scott, who a little later became a Roman Catholic with him, stated his conviction that the alternative was "either Rome or licence of thought and will." He was received into the Roman Catholic Church by Father Brownhill, S.J., at the church in Farm Street, on Passion Sunday, 6th April 1851. On the following Sunday he was confirmed and received to communion by Cardinal Wiseman, who also, within ten weeks of his reception, ordained him priest. Manning thereupon proceeded to Rome to pursue his theological studies, residing at the college known as the "Academy for Noble Ecclesiastics," and attending lectures by Perrone and Passaglia among others. The Pope frequently received him in private audience, and in 1854 conferred on him the degree of D.D. During his visits to England he was at the disposal of Cardinal Wiseman, who through him, at the time of the Crimean war, was enabled to obtain from the Government the concession that for the future Roman Catholic army chaplains should not be regarded as part of the staff of the Protestant chaplain-general. In 1857 the Pope, *proprio motu*, appointed him provost (or head of the chapter) of Westminster, and the same year he took up his residence in Bayswater as superior of a community known as the "Oblates of St Charles," an association of secular priests on the same lines as the institute of the Oratory, but with this difference, that they are by their constitution at the beck and call of the bishop in whose diocese they live. The community was thus of the greatest service to Cardinal

Wiseman, whose right-hand man Manning thenceforward became. During the eight years of his life at Bayswater he was most active in all the duties of the priesthood, preaching, hearing confessions, and receiving converts; and he was notably zealous to promote in England all that was specially Roman and papal, thus giving offence to old-fashioned Catholics, both clerical and lay, many of whom were largely influenced by Gallican ideas, and had with difficulty accepted the restoration of the hierarchy in 1850. In 1860 he delivered a course of lectures on the Pope's temporal power, at that date seriously threatened, and shortly afterwards he was appointed a papal "Domestic Prelate," thus becoming a "Monsignor," to be addressed as "Right Reverend." He was now generally recognized as the able and effective leader of the Ultramontane party among English Roman Catholics, acting always, however,

in subordination to Cardinal Wiseman; and on the latter's death (15th February 1865) it was felt that, if Manning should succeed to the vacant archbishopric, the triumph of Ultramontanism would be secured. Such a consummation not being desired by the Westminster chapter, they submitted to the Pope three names, and Manning's was not one of them. Great efforts were made to secure the succession for the titular archbishop Errington, who at one time had been Wiseman's coadjutor with that right reserved to him, but who had been ousted from that position by the Pope acting under Manning's influence. In such circumstances Pius IX. could hardly do otherwise than ignore Errington's nomination, as he also ignored the nomination of Clifford, bishop of Clifton, and of Grant, bishop of South-

CARDINAL MANNING.

wark; and, by what he humorously described as "the Lord's own *coup d'état*," he appointed Manning to the archiepiscopal see. Consecrated at the pro-cathedral at Moorfields (since destroyed) by Dr Ullathorne, bishop of Birmingham (8th June 1865), and enthroned there (6th November), after receiving the *palium* in Rome, Manning began his work as archbishop by devoting himself especially to the religious education of the poor and to the establishment of Catholic industrial and reformatory schools. He steadily opposed whatever might encourage the admission of Catholics to the national universities, and so put his foot down on Newman's project to open a branch house of the Oratory at Oxford with himself as superior. He made an unsuccessful and costly effort to establish a Catholic university at Kensington, and he also made provision for a diocesan seminary of strictly ecclesiastical type. Jealous of the exclusive claims of the Roman Church, he procured a further condemnation at Rome of the "Association for the Promotion of the Unity of Christendom," which advocated prayers for the accomplishment of a kind of federal union between the Roman, Greek, and Anglican Churches, and in a pastoral letter he insisted on the heretical assumption implied in such an undertaking. He also worked for the

due recognition of the dignity of the secular or pastoral clergy, whose position seemed to be threatened by the growing ascendancy of the regulars, and especially of the Jesuits, whom, as a practically distinct organization within the Church, he steadily opposed. In addition to his diocesan synods, he presided in 1873 over the fourth provincial synod of Westminster, which legislated on "acatholic" universities, church music, mixed marriages, and the order of a priest's household, having previously taken part, as theologian, in the provincial synods of 1853 and 1859, with a hand in the preparation of their decrees. But it was chiefly through his strenuous advocacy of the policy of defining papal infallibility at the Vatican council (1869-70) that Manning's name obtained world-wide renown. In this he was instant in season and out of season. He brought to Rome a petition in its favour from his chapter at Westminster, and during the progress of the council he laboured incessantly to overcome the opposition of the "inopportunist," his belief in the importance of the definition for the welfare of the Church being as deep as it was sincere. And he never ceased to regard it as one of the chief privileges of his life that he had been able to take an active part in securing the definition, and in having heard with his own ears that doctrine proclaimed as a part of divine revelation. In 1875 he published a reply to Gladstone's attack on the Vatican decrees; and on 15th March in that year he was created cardinal, with the title of SS. Andrew and Gregory on the Coelian. He was present at the death of Pius IX. (7th February 1878); and in the subsequent conclave, while some Italian cardinals were prepared to vote for his election to fill the vacant chair, he himself supported Cardinal Pecci, afterwards known as Leo XIII. With him, however, Manning found less sympathy than with his predecessor, though Manning's advocacy of the claims of labour attracted Leo's attention, and influenced the encyclical which he issued on the subject. After the Vatican council, and more especially after the death of Pius IX., Manning devoted his attention mainly to social questions, and with these his name was popularly associated during the last fifteen years of his life. From 1872 onwards he was a strict teetotaler, not touching alcohol even as a medicine, and there was some murmuring among his clergy that his teaching on this subject verged on heresy. But his example and his zeal profoundly influenced for good the Irish poor forming the majority of his flock; and the "League of the Cross" which he founded, and which held annual demonstrations at the Crystal Palace, numbered nearly 30,000 members in London alone in 1874. He sat on two royal commissions, the one on the housing of the working classes (1884), and the other on primary education (1886); and in each case the report showed evident marks of his influence, which his fellow-commissioners recognized as that of a wise and competent social reformer. In the cause of labour he was active for many years, and in 1872 he set an example to the clergy of all the churches by taking a prominent part in a meeting held in Exeter Hall on behalf of the newly-established Agricultural Labourers' Union, Joseph Arch and Charles Bradlaugh being among those who sat with him on the platform. In later years his strenuous advocacy of the claims of the working classes, and his declaration that "every man has a right to work or to bread," led to his being denounced as a Socialist. That he was such he denied more than once (Lemire, *Le Cardinal Manning et son Action Sociale*, Paris, 1893, p. 210), nor was he ever a Socialist in principle; but he favoured some of the methods of Socialism, because they alone seemed to him practically to meet the case of that pressing poverty which appealed to his heart.

He took a leading part in the settlement of the dockers' strike in the autumn of 1889, and his patient and effectual action on this and on similar occasions secured for him the esteem and affection of great numbers of working men, so that his death on 14th January 1892, and his funeral a week later, were the occasion for a remarkable demonstration of popular veneration. The Roman Catholic cathedral at Westminster is his joint memorial with his predecessor, Cardinal Wiseman.

Whatever may have been the value of Manning's services to the Roman Catholic Church in England in bringing it, as he did, up to a high level of what in earlier years was commonly denounced as Ultramontaniam, it is certain that by his social action, as well as by the earnestness and holiness of his life, he greatly advanced in the minds of his countrymen generally their estimate of the character and value of Catholicism. Pre-eminently he was a devout ecclesiastic, a "great priest"; and his sermons, both Anglican and Catholic, are marked by fervour and dignity, by a conviction of his own authoritative mission as preacher, and by an eloquent insistence on considerations such as warm the heart and bend the will rather than on such as force the intellect to assent. But many of his instincts were those of a statesman, a diplomatist, a man of the world, even of a business man; and herein lay, at least in part, the secret of his influence and success. Intellectually he did not stand in the front rank. He was neither a philosopher nor a literary genius. Among his many publications, written, it is only fair to admit, amidst the urgent pressure of practical work, there is barely a page or even a sentence that bears the stamp of immortality. But within a somewhat narrower field he worked with patience, industry, and self-denying zeal; his ambition, which seemed to many personal, was rather the outcome of his devotion to the cause of the Church; and in the later years of his life especially he showed that he loved righteousness and hated iniquity, and that he realized as clearly as any one that the service of God was incomplete without the service of man.

The publication in 1896 of Manning's *Life*, by Purcell, was the occasion for some controversy on the ethics of biography. Edward Purcell was an obscure, inaccrurate, and small-minded Catholic journalist, to whom Manning, late in life, had entrusted, rather by way of charitable bequest, his private diaries and other confidential papers. It thus came to pass that in Purcell's voluminous biography much that was obviously never intended for the public eye was, perhaps inadvertently, printed, together with a good deal of ungenerous comment. The facts disclosed which mainly attracted attention were—(1) that Manning, while yet formally an Anglican, and while publicly and privately dissuading others from joining the Roman Catholic Church, was yet within a little convinced that it was his own duty and destiny to take that step himself; (2) that he was continually intriguing at the back-stairs of the Vatican for the furtherance of his own views as to what was desirable in matters ecclesiastical; (3) that his relations with Newman were very unfriendly; and (4) that, while for the most part he exhibited towards his own clergy a frigid and masterful demeanour, he held privately very cordial relations with men of diverse religions or of no theological beliefs at all. And certainly Manning does betray in these autobiographical fragments an unheroic sensitiveness to the verdict of posterity on his career. But independent critics (among whom may specially be named M. François de Pressensé) held that Manning came well through the ordeal, and that Purcell's *Life* has great value as an unintentionally frank revelation of character.

Manœuvres, Military.—Manœuvres may be defined as the higher training for war of troops of all arms in large bodies, and have been carried out in most countries ever since the first formation of standing armies. In England no manœuvres or camps of exercise appear to have been held till the beginning of the 19th century, when Sir John Moore trained the famous Light Brigade at the camp of Shorncliffe. In France, however, under Louis XIV., large camps of instruction were frequently held, the earliest recorded being that of 18,000 troops at Compiègne in 1666; and these were continued at intervals under his successor. At these French camps much time was devoted to ceremonial, and the manœuvres performed were of an elementary description. Still their effect upon the training of the army for war was far-reaching, and bore fruit in the numerous wars in the first half of the 18th century. Other countries followed suit, but it was reserved for Frederick the Great to inaugurate a system of real manœuvres, and to develop on the training-ground the system of tactics which bore such good fruit in his various campaigns. The numbers of troops assembled were large; for example, at Spandau in 1753, when 36,000 men carried out manœuvres for twelve days. The king laid the greatest stress on these exercises, and took immense pains to turn to account the experience gained in his campaigns. Great secrecy was observed, and before the Seven Years' War no stranger was allowed to be present. The result of all this careful training was shown in the Seven Years' War, and after it the Prussian manœuvres gained a reputation which they have maintained to this day. But with the passing away of the great king they became more and more pedantic, and the fatal results were shown in 1806. After the Napoleonic wars, yearly manœuvres became the custom in every large Continental army. Great Britain alone thought she could dispense with them, perhaps because of the constant practical training her troops and officers received in the various Indian and colonial wars; and it was not till 1853 that, by the advice of the Prince Consort, a body of troops were gathered together for a camp of exercise on Chobham Common, and that eventually a standing camp of exercise was evolved out of the temporary camp formed during the Crimean War at Aldershot.

Most Continental armies have, since the great successes of the Germans in 1870, copied more or less their system of military training; hence it is appropriate to consider their methods first. The whole training of the army is based on a yearly programme of gradual progression, from the joining of the recruits in October to the training by squads, companies, battalions, and regiments, the latter finishing their field training about the middle of August, when the manœuvre period begins. First of all, the brigades go through five working days of drills on flat ground, to get them under the hand of their commanders and prepare them for manœuvres. Then follow ten working days of manœuvres in new and varied ground, of which four are "brigade," four "divisional," and two "corps" manœuvres, in each case the unit named being divided into two portions of all arms, which manœuvre against one another. Each year two or more army corps carry out manœuvres before the Emperor, working against one another, the largest body ever assembled having been four corps, 117,000 men, near Homburg in 1897. The chief feature of the German manœuvres is the free hand allowed to leaders of sides. Of course, for reasons of supply and transport, it is necessary to keep the troops within a certain area, but the general and special ideas are so framed that, while retaining their own initiative, the leaders of sides have to give such orders as will suit the arrangements made by the director of manœuvres for supply. The faculty of quartering troops on private individuals to any extent, and the fact of the troops being provided with portable tent equipment, give great latitude to the German leaders in their choice of quarters for troops, and so increase the similitude of manœuvres to war. The Austrian and Italian manœuvres are a close copy of the German, but those of the French present the peculiarity of a certain amount of prearrangement, especially at grand manœuvres, when it is frequently laid down beforehand which side is to be victorious. Thus a series of pictures of war is presented, but the manœuvres are hardly a test of the skill of

the rival leaders. In Russia the climatic and social conditions, and the distribution of the army, necessitate a quite peculiar system. The troops leave their barracks and move into standing camps generally in May, and in these for about three months their training up to that in battalions is carried out on the drill ground. Camps of mixed units are then formed for a month, and from them, but always over the same ground, the manœuvres of regiments, brigades, and divisions are performed. Then follow the so-called mobile manœuvres, which last for ten days or a fortnight. At some of these large masses are assembled, as in Volhnia in 1890, when 194 battalions, 140 squadrons, and 82 batteries were engaged. Of all European manœuvres these are perhaps the nearest approach to war, for the sides start a great distance apart, and ample time is allowed for cavalry reconnaissance. Besides, the Russian soldier does not require elaborate arrangements for supply; hence the director is not so tied down by consideration of this matter as in other armies.

In England the military authorities have long been hampered in the organization of manœuvres by the necessity of carrying them out on very limited portions of Government land or on areas lent as a favour by, or hired from, private individuals. There has been no want of recognition by the military authorities of the necessity for, and value of, manœuvres, and the training at the camps of instruction has been supplemented as far as possible by small manœuvres on such portions of country as could be made available. But, with the exception of spasmodic efforts in 1871 and 1872, it was not until 1897 that the Government allowed itself to be convinced by its military advisers, and passed a Military Manœuvres Act, by which certain districts could be "proclaimed" for purposes of manœuvres, and troops in consequence could traverse all ground. In 1898 the first manœuvres under this Act were held in Wilts and Dorset, and were intended to be repeated at fixed intervals in future years. In addition, every effort was made to add to the existing permanent training grounds for troops, and ground was acquired on Salisbury Plain with the intention of developing it into a second Aldershot. But the training on those well known grounds, excellent as it is in itself as a preparation, is not "manœuvres," and never can do away with the necessity for them, with a more or less free hand given to the leaders over fresh country.

Much misconception prevails as to the nature and limitation of the military instruction to be imparted at manœuvres. Manœuvres are a school for the leaders, in a less degree for the led, and consequently the minor details of instruction must be completed, and the troops fully trained as units, before they can take part in them with advantage. The time during which large bodies of troops can be kept together for manœuvres is too short, and the expense too great, to justify time being spent on exercises which might as well be carried out in the ordinary stations or at the great training camps. Therefore it may be laid down as a principle that manœuvres, properly so-called, should be begun with units not smaller than a brigade of infantry on each side, with a due proportion of the other arms attached. It is useful if these can precede the manœuvres of larger bodies, as the training is then progressive and the result more satisfactory.

The choice of ground is of great importance. Its extent should be proportionate to the force to be employed and the nature of the instruction to be imparted. It should not be too hilly nor yet too flat, but both descriptions should be judiciously combined; and regard must be had to the water supply, and the road and railway net for the convenience of the supply service. Once the ground has been selected, the general and special ideas must be so framed that the troops are thereby confined to the chosen ground without seeming to tie the hands of the leaders of sides. It is of great advantage if the same idea can be maintained throughout each series of operations, as thereby the interest of all concerned and the likeness to actual warfare are increased; and, if possible, the "state of war" should be continuous also. Within the limits of the special idea, the utmost latitude should be left to leaders; but if the orders of one or both sides seem to render a collision unlikely, the director should so modify the special idea as to compel one or other to re-cast his orders in such a way that contact is brought about. Such interference will scarcely be necessary after the first issues of orders in each series. In war the number of marching days vastly outnumbers those of fighting, but in manœuvres this must not be allowed; tactical instruction is what is desired, and a manœuvre day in which none is imparted is not fully utilized. It is not necessary that all the troops should be engaged, but at least the advanced bodies must come into contact, and the rest must carry out marches as on active service. Each action should be fought to its end, "Cease firing" being sounded when the crisis has been reached; and on a decision being given by the director, one side should retire and the fight be broken off in a proper military manner. The troops should place outposts each day, and act in all respects as if on active service.

The quartering and supply of troops are the chief difficulties in the arrangement of manœuvres, and afford ample opportunity for the practising of the officers and departments responsible for these matters. In England, where in peace it is not possible to billet troops on private individuals, quartering must be replaced by encampments or bivouacs, and the selection of ground for them affords invaluable practice. If possible, their position should be selected to conform to the military situation; but if it is found necessary, for reasons of water or food supply, to withdraw troops to positions other than such as they would occupy in real warfare, time should be allowed them on the following day to regain the positions they would otherwise have occupied. It is next to impossible, for various reasons, financial and other, to organize the food supply in manœuvres as it would be in war. Sufficient transport *cadres* cannot be kept up in peace, and consequently recourse must be had to hired transport, which cannot be treated as a military body. Again, food cannot be requisitioned, and local purchase at the time cannot be trusted to; so depôts of supplies must be formed beforehand in the manœuvres area, which more or less tie the hands of the supply service. Still, with a judicious choice of the points at which these are formed, much may be done to approximate to service conditions, and the more nearly these are realized the more instructive for the supply will the manœuvres become.

Finally, a word must be said as to the umpire staff, which represents the bullets. The most careful selection of officers for this important duty is necessary, and they must have sufficient authority and be in sufficient number to make their influence everywhere felt. Their principal object should be to come to a decision quickly, so as to prevent the occurrence of unreal situations; and by constant intercommunication they must ensure uniformity in their decisions, and so maintain continuity of the action all over the manœuvres battlefield.

(J. M. GR.)

Manor.—It will be most convenient to describe a typical English manor in its best known period, the 13th century, and to indicate briefly the modifications of the type which varying conditions may produce. Topographically such a manor consisted partly of the houses of the inhabitants more or less closely clustered together, and surrounded by the arable land divided into large fields, two or three in number. Each of these fields was divided again into shots or furlongs, and each of the shots was broken up into cultivated strips a pole wide, each containing an acre, separated by narrow balks of turf. There were also certain meadows for supplying hay; and beyond the cultivated land lay the wood and waste of the manor. Portions of arable or meadow land might be found apart from the organization of the remainder; the lord of the manor might have a park, and each householder a garden, but the land of the manor was the open fields, the meadows, and the wastes or common. The condition of the inhabitants of such a manor is as complex as its geography. At the head of the society came the lord

Rights of lord and tenants.

of the manor, with his hall, court, or manor-house, and the land immediately about it, and his demesne both in the fields and in the meadow land. The arable demesne consisted of certain of the acre strips lying scattered over the various furlongs; his meadow was a portion assigned to him each year by the custom of the manor. He had also rights over the surrounding waste paramount to those enjoyed by the other inhabitants. Part of his demesne land would be granted out to free tenants to hold at a rent or by military or other service; part would be in the lord's own hands, and cultivated by him. Each part so granted out will carry with it a share in the meadow land and in the profits of the waste. These rights of the free tenants over the waste limited the lord's power over it. He could not by enclosure diminish their interest in it. The statute of Merton (20 Henry III.) and the second statute of Westminster (Edward I.) marked the utmost limit of enclosure allowed in the 13th century. Below the lord and the free tenants came the villeins, natives, bondmen, or holders of *virgates* or yard-lands, each holding a house, a fixed number of acre strips, a share of the meadow and of the profits of the waste. The number of strips

so held was usually about thirty; but virgates of fifteen acres or even eighty are not unknown. In any one manor, however, the holdings of all the villeins were equal. Normally the holder of a virgate was unfree; he had no rights in the eye of the law against his lord, who was protected from all suits by the *exceptio villenagii*; he could not without leave quit the manor, and could be reclaimed by process of law if he did; the strict contention of law deprived him of all right to hold property; and in many cases he was subject to certain degrading incidents, such as *merchet*, a payment due to the lord upon the marriage of a daughter, which was regarded as a special mark of unfree condition. But there are certain limitations to be made: firstly, all these incidents of tenure, even *merchet*, might not effect the personal status of the tenant; he might still be free, though holding by an unfree tenure; secondly, even if unfree, he was not exposed to the arbitrary will of his lord, but was protected by the custom of the manor as interpreted by the Manor Court. Moreover, he was not a slave; he was not bought and sold apart from his holding. The hardship of his condition lay in the services due from him. As a rule a villein paid for his holding in money, in labour, and in kind. In money he paid, firstly, a small fixed rent called rent of assize; and, secondly, dues under various names, partly in lieu of services commuted into money payments, and partly for the privileges and profits enjoyed by him on the waste of the manor. In labour he paid more heavily. Week by week he had to come with his own plough and oxen to plough the lord's demesne; when ploughing was done he had to harrow, to reap the crops, to thresh and carry them, or do whatever might be required of him, until his allotted number of days' labour in the year was done. Beyond this his lord might request of him extra days in harvest or other seasons of emergency, and these requests could not be denied. Further, all the carriage of the manor was provided by the villeins, even to places as much as a hundred miles away from the manor. The mending of the ploughs, hedging, ditching, sheep-shearing, and other miscellaneous work, also fell upon him, and it is sometimes hard to see what time remained to him to work upon his own holding. In kind he usually rendered honey, eggs, chickens, and perhaps a ploughshare, but these payments were almost always small in value. Another class of inhabitants remains to be mentioned—the cotters. These are the poor of the manor, who hold a cottage and garden, or perhaps one acre or half an acre in the fields. They were unfree in condition, and in most manors their services were modelled upon those of the villeins. From their ranks were usually drawn the shepherd of the manor, the bee-keeper, and other minor officials of the manor.

Rights of villeins.

Cotters.

A complicated organization necessarily involves administrators. Just as the services of the tenants and even their names vary from manor to manor, so does the nature of the staff. Highest in rank came the steward; he was attached to no manor in particular, but controlled a group, travelling from one to another to take accounts, to hold the courts, and generally represent the lord. Under him are the officers of the several manors.

Staff.

First came the bailiff or beadle, the representative of the lord in the manor; his duty was to collect the rents and services, to gather in the lord's crops, and account for the receipts and expenditure of the manor. Closely connected with him was the "messor" or reaper; in many cases, indeed, "reaper" seems to have been only another name for the bailiff. But the villeins were not without their own officer, the provost or reeve. His duty was to arrange the distribution of the services due from the tenants, and, as their representative, to assist the bailiff in the management

of the manor. Sometimes the same man appears to have united both offices, and we find the reeve accounting to the lord for the issues of the manor. To these important officials may be added a number of smaller ones, the shepherd, the swine-herd, the bee-keeper, the cow-herd, the ploughman, and so on, mostly selected from the cotters, and occupying their small holdings by the services expressed in their titles. The number varies with the constitution and needs of each estate, and they are often replaced by hired labour.

The most complicated structure in the system is the Manor Court. The complication is, indeed, partly the work of lawyers interpreting institutions they did not understand by formulæ not adapted to describe them. But

Manor Court.

beyond this there remain the facts that the court was the meeting-point of the lord and the tenants both free and unfree, that any question touching on the power and constitution of the court was bound to affect the interests of the lord and the tenants, and that there was no external power capable of settling such questions as did arise. Amid this maze a few clear lines can be laid down. In the first place, so far as the 13th century goes, all the discussion that has collected about the terms court-leet, court-baron, and court-customary may be put aside; it relates to questions which in the 13th century were only just emerging. The Manor Court at that date exercised its criminal, civil, or manorial jurisdiction as one court; its names may differ, the parties before it may be free or unfree, but the court is the same. Its president was the lord's steward; the bailiff was the lord's representative and the public prosecutor; and the tenants of the manor, both free and unfree, attended at the court and gave judgment in the cases brought before it. To modern ears the constitution sounds unfamiliar. The president of the court settled the procedure of the court, carried it out, and gave the final sentence, but over the law of the court he had no power. All that is comprised in the word "judgment" was settled by the body of tenants present at the court. This attendance was, indeed, compulsory, and absence subjected to a fine any tenant owing and refusing the service known as "suit of court." It may be asked who in these courts settled questions of fact. The answer must be that disputed questions of fact could only be settled in one way, by ordeal; and that in most manorial courts the method employed was the wager of law. The business of the court may be divided into criminal, manorial, and civil. Its powers under the first head depended on the franchises enjoyed by the lord in the particular manor; for the most part only petty offences were triable, such as small thefts, breaches of the assize of bread and ale, assaults, and the like; except under special conditions, the justice of great offences remained in the king. But offences against the custom of the manor, such as bad ploughing, improper taking of wood from the lord's woods, and the like, were of course the staple criminal business of the court. Under the head of manorial business the court dealt with the choice of the manorial officers, and had some power of making regulations for the management of the manor; but its most important function was the recording of the surrenders and admittances of the villein tenants. Into the history and meaning of this form of land transfer it is not necessary to enter here. But it must be noted that the conveyance of a villein's holding was effected by the vendor surrendering his land to the lord, who thereupon admitted the purchaser to the holding. The same procedure was employed in all cases of transfer of land, and the transaction was regularly recorded upon the rolls of the court among the records of all the other business transacted there. Finally, the court dealt with all suits

as to land within the manor, questions of dower and inheritance, and with civil suits not connected with land. But it need hardly be said that in an ordinary rural manor very few of these would occur.

It will be clear on consideration that the Manor Court as here described consisted of conflicting elements of very different origin and history. Founded partly on express grants of franchises, partly on the inherent right of a feudal lord to hold a court for his free tenants, partly on the obscure community traceable among the unfree inhabitants of the manor, it is incapable of strict legal definition. All these elements, moreover, contain in themselves reasons for the decay which gradually came over the system. The history of the decay of the manorial jurisdictions in England has not yet been written. On the one hand were the king's courts, with new and improved processes of law; on the other hand the gradual disintegration which marks the history of the manor during the 14th and 15th centuries. The criminal jurisdiction was the first to disappear, and was closely followed by the civil jurisdiction over the free tenants; and in modern times all that is left is the jurisdiction over the customary tenants and their holdings, and that in an attenuated form.

A few words must be given to the legal theories of the 15th century on the Manor Court. It would seem to have become the law that to the existence of the manor two courts were necessary—a court customary for customary tenants, and a court baron for free tenants. In the court customary the lord's steward is the judge; in the court baron the freeholders are the judges. If the freeholders in the manor diminish to less than two in number the court baron cannot be held, and the manor perishes. Nor can it be revived by the grant of new freehold tenures, because under the statute of *Quia Emptores* such new freeholders would hold not of the lord of the manor, but of his lord. The customary tenants and the court customary may survive, but the manor is only a reputed manor. Of the 13th century all this is untrue, but even at that date the existence of free tenants was in a measure essential to the existence of the Manor Court. If there were none the jurisdiction of the court over free tenants of course collapsed; but in addition to this the lord also lost his power of exercising the highest criminal franchises, even if he otherwise possessed them; he could, for instance, no longer hang a murderer on his own gallows. Perhaps it may be said that to the exercise of the feudal power and of the royal franchises the presence of free tenants was necessary. But it is clear that no such condition was necessary to the existence of the manor.

Apart from the change in the court of the manor, the most important thread in its history is the process which converted the villein into the copyholder. Here again the subject is imperfectly explored, and part of it is still subject to controversy. In the strict view of contemporary lawyers the holding of the villein tenant of the 13th century was at the will of the lord, and the king's courts of law would not protect him in his possession. If, however, the villein were a tenant on the king's ancient demesne his condition was improved. The writs of *monstraverunt* and the little writ of right close protected him from the improper exaction of services and from ejection by the lord. But in ordinary manors there was no such immunity. That ejection was common cannot be believed, but it was legally possible; and it was not until the well-known decision of Danby, C.J., and Bryan, C.J., in 7 Edw. IV., that the courts of law would entertain an action of trespass brought against his lord by a customary tenant. From that date the courts both of law and equity begin to intervene; and the records of the Courts of Star Chamber and Requests show that in the Tudor period equitable suits brought by tenants against their lords are not infrequent. Side by side with the alteration in the legal condition of the manor there went on an economic change. The labour rents and other services slowly disappeared, and were replaced by money payments. The field divisions gave way before enclosures, effected sometimes by the lords and sometimes by the tenants. Change in legal and agricultural practice went on side by side, and finally the manor ceased to be an important social form, and became only a peculiar form of land tenure and the abode of antiquarian curiosities.

Manresa, a town of Spain, in the province of Barcelona, 30 miles from Barcelona. Its population, 22,685 in 1887, increased to 25,931 in 1897, with the development of the local industries—manufactures of woollen, cotton, and linen goods, ribbons, hats, leather, soap, paper, chemicals, alcohol, and flour, and iron-founding—which have thriven since 1892. A new town has sprung up on the right bank of the river Cardenero. A canal 18 miles long connects with the river Llobregat.

Mans, Le, chief town of department Sarthe, and headquarters of the 4th Army Corps, France, 133 miles south-west of Paris by the railway to Brest. The suburb of Pré on the right bank of the river covers an area three times that of the old town, and in its westward extension embraces the former town of St Pavin-des-Champs. Steam tramways connect the town with several outlying places. Population (1881), 43,178; (1901), 63,272.

Mansfield, a municipal borough (1891) in the Mansfield parliamentary division of Nottinghamshire, England, in Sherwood Forest, on the river Mann or Maun, 17 miles north by west of Nottingham by rail. A free library has been opened. The manufacture of boots is important. Population (1891), 15,925; (1901), 21,441.

Mansfield, a city of Ohio, U.S.A., capital of Richland county, in the northern part of the state, at an altitude of 1151 feet. It has a regular plan, is divided into ten wards, and has three railways, the Baltimore and Ohio, the Erie, and the Pennsylvania. It has extensive manufactures, especially of agricultural implements. Population (1890), 13,473; (1900), 17,640, of whom 1781 were foreign-born, and 123 were negroes.

Mansurah, a town of Lower Egypt, capital of the province of Dakahlieh, near the west side of Lake Menzaleh, an important railway station on the Cairo-Damietta line, with population (1900) 27,000. It dates from 1221, and was famous in the wars of the Crusaders, Louis IX. having been imprisoned here after his disastrous retreat and capture in 1250. It has several cotton-ginning, cotton, linen, and sail-cloth factories.

Mantes, chief town of arrondissement and railway station, department of Seine-et-Oise, France, 27 miles north-west of Versailles, on the left bank of the Seine, which separates it from Limay. The 15th-century auditorium of the cathedral church of Notre Dame is now the seat of the civil tribunal, the Hôtel de Ville dates from the 17th century, and there is a beautiful fountain of the Renaissance period. The principal manufactures are musical instruments and artificial incubators. Poultry-rearing is an important industry, and there is commerce in cereals, fruits, and vegetables. In 1087 William the Conqueror, when besieging the town, met with the accident which cost him his life. The castle, demolished in 1721, was visited by several sovereigns. Population (1881), 5847; (1901), 8034.

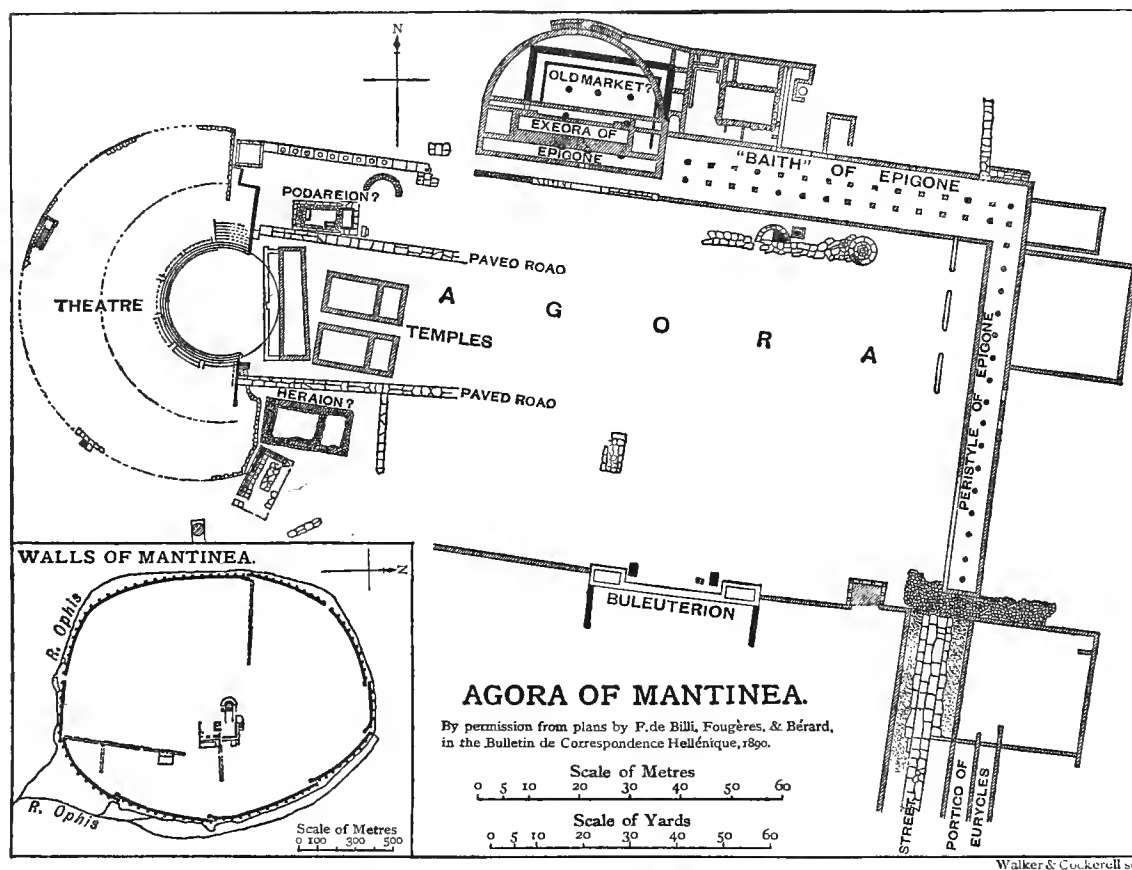

Manteuffel, Edwin Hans Karl von, FRIEHER (1809-1885), Prussian field-marshal, son of the president of the Superior Court of Magdeburg, was born at Dresden on the 24th February 1809. He was brought up with his cousin, Otto von Manteuffel (1805-1882), the Prussian statesman, entered the Dragoon

Guards at Berlin in 1827, and was promoted lieutenant in 1828. After attending the War Academy for two years, and serving successively as adjutant to General von Müffling and to Prince Albert of Prussia, he was promoted captain in 1843 and major in 1848, when he became aide-de-camp to Frederick William IV., whose confidence he enjoyed. Promoted lieutenant-colonel in 1852, and colonel to command the 5th Uhlans in 1853, he was sent on important diplomatic missions to Vienna and St Petersburg. In 1857 he became major-general and chief of the military cabinet, an invidious post, in which he had to deal with the personal merits of the officers of the army, and promote or weed them out as he thought desirable. He gave hearty support to the Prince Regent's plans for the reorganization of the army. In 1861 he was violently attacked in a pamphlet by Herr Twesten, a Liberal leader, whom he wounded in a duel. He served as lieutenant-general in the Danish war of 1864, and at its conclusion was appointed civil and military governor of Schleswig. He took the initiative in the Austrian war of 1866 by ejecting the Austrians from Holstein, commanded a division under Vogel von Falkenstein in the Hanoverian campaign, and succeeded him, in July, in command of the army of the Main. His successful operations ended with the occupation of Würzburg, and he then went on a diplomatic mission to St Petersburg, where he was *persona grata*, and succeeded in gaining Russia's assent to the new position in North Germany. He was appointed to the command of the ninth army corps in 1866, and transferred to the first corps in 1868. In the Franco-German war of 1870-71 he commanded the first army corps under Steinmetz, distinguishing himself in the fighting round Metz—in the battles of Colombey and Neuilly, and especially in the repulse of Bazaine at Noisseville. He succeeded Steinmetz in October in the command of the first army, won the battle of Amiens against General Farre, and occupied Rouen, but was less fortunate against Faidherbe at Pont Noyelles and Bapaume. In January 1871 he commanded the newly-formed army of the south, which he led, in spite of hard frost, through the Côte d'Or and over the plateau of Langres, cut off Bourbaki's army of the east (80,000 men), and, after the action of Pontarlier, compelled it to cross the Swiss frontier, where it was disarmed. The southern army was disbanded, and Manteuffel commanded, first, the second army, and, from June 1871, the army of occupation left in France until 1873, showing great tact in a difficult position. He was made a field-marshal for his services, went on several diplomatic missions, was for a time governor of Berlin, and in 1879 was appointed governor-general of Alsace-Lorraine; and this office he held until his death at Karlsbad, Bohemia, on 17th June 1885. (R. H. V.)

Mantineia.—The site of Mantineia was excavated by M. Fougères, of the French School at Athens, in 1888. The plan of the agora and adjacent buildings has been recovered, and the walls have been completely investigated. The town was situated in an unusual position for a Greek city, on a flat marshy plain, and its walls form a regular ellipse about 4 kilometres in circumference. When the town was first formed in 470 B.C. by the "synœcism" of the neighbouring villages, the river Ophis flowed through the midst of it, and the Spartan king Agesipolis dammed it up below the town and so flooded out the Mantineans and sapped their walls, which were of unbaked brick. Accordingly, when the city was rebuilt in 370 B.C., the river Ophis was divided into two branches, which between them encircled the walls; and the walls themselves were constructed to a height of about 3 to 6 feet of stone, the rest being of unbaked brick. These are the walls of which the remains

are still extant. There are towers about every 80 feet; and the gates are so arranged that the passage inwards usually runs from right to left, and so an attacking force would have to expose its right or shieldless side. Within the walls the most conspicuous landmark is the theatre, which, unlike the majority of Greek theatres, consists entirely of an artificial mound standing up from the level plain. Only about a quarter of its original height remains. Its *scena* is of rather irregular shape, and borders one of the narrow ends of the agora. Close to it are the

foundations of several temples, one of them sacred to the hero Podaros. The agora is of unsymmetrical form; its sides are bordered by porticoes, interrupted by streets, like the primitive agora of Elis as described by Pausanias, and unlike the regular agoras of Ionic type. Most of these porticoes were of Roman period—the finest of them were erected, as we learn from inscriptions, by a lady named Epigone; one, which faced south, had a double colonnade, and was called the *Bairn*; close to it was a large exedra. The foundations of a square market hall of earlier date

were found beneath this. On the opposite side of the agora was an extensive Buleuterion or senate-house. Traces remain of paved roads both within the agora and leading out of it; but the whole site is now a deserted and feverish swamp. The site is interesting for comparison with Megalopolis; the nature of its plan seems to imply that its main features must survive from the earlier "synoecism," a century before the time of Epaminondas.

See *Bulletin de Correspondance Hellénique*, 1890, G. Fougères; *Mantinee et l'Arcadie orientale*, Paris, 1898. (E. GR.)

Mantua (Italian *Mantova*), a fortified town and capital of the province of Mantua, Italy, on the river Mincio, 71 miles east-south-east of Milan by rail. It possesses an antiquarian museum, which ranks as one of the most important in North Italy. The educational institutions embrace also a chemical laboratory, a botanical garden, and a mineralogical museum. Amongst the industries are iron-works, tanneries, printing, furriery, doll-making, and flour-mills. The champion of Tyrolese liberty, Andreas Hofer, was shot at Mantua by the French in 1810. Population (1881), 28,048; (1901), 29,160.

Manures. See AGRICULTURE.

Manzanares, a town of Spain, in the province of Ciudad Real. Its population was 9700 in 1887, and

10,447 in 1897. An ancient castle dates from the 13th century. Manzanares is the seat of an active trade in wine, aniseed, saffron, wheat, and alcohol; local industries include manufactures of chalk, bricks, and soap, and distilling.

Manzanillo, an important commercial city of Cuba, situated at the mouth of the Rio Cauto in Santiago province. It exports large quantities of sugar, hides, tobacco, and bees-wax. The last battle of the Spanish-American war was in progress here when the protocol of peace was signed. Population (1899), 14,464.

Map.—Since 1875 topographical surveys have gained much in accuracy, and thus, whilst formerly it was deemed sufficient if a topographical map answered the requirements of the soldier, such a map, before it can be accepted as satisfactory at the present day, must equally meet the interests of the civil engineer and of the man of science. Various processes for the production of maps have been perfected and are extensively employed. Photography, including heliogravure, has in this manner largely superseded the more tedious processes of engraving on copper or stone, and the time thus gained may fairly be considered to compensate for a less attractive appearance when printed. Topographical maps of the

more perfect type are still exceedingly rare. As a rule, maps of this kind are based upon the cadastral plans adjusted to a trigonometrical survey, the additional details required for military purposes being filled in with the aid of plane-table and tacheometer. The contours (Isopyreæ) are merely sketched in, and are dependent upon a limited number of altitudes determined with more or less accuracy. Where cadastral plans are not available recourse is had to the plane-table, and occasionally, but only in mountainous districts, to photographic surveying or photogrammetry.

Topographical Surveys.—The year 1855 marks an entirely new departure in the work of the Ordnance Survey of the United Kingdom, for in that year it was determined that cities and towns should thenceforth be surveyed on a scale of 1 : 500 (10-foot scale) or 1 : 1056 (5-foot scale), agricultural districts on a scale of 1 : 2500 (25-inch scale), and that the old 6-inch scale (1 : 10,560) should be retained for uncultivated hilly districts and for a general map of the whole kingdom. The contour lines inserted upon these large scale maps or plans are based upon instrumental measurement. As regards Great Britain, the whole of this survey was completed and published in 1895. This rapid publication was rendered possible by substituting zincography for the tedious process of copper engraving. It is upon maps of this minute accuracy that the popular "New Series" of the 1-inch scale (1 : 63,360) is based. This 1-inch map, in outline, including contours at intervals of 50 or 100 feet, was completed for the whole of the United Kingdom in 1896, and many sheets of it have since been thoroughly revised and brought up to date. In the second edition the hills are hachured in black. There are also in progress an edition with the hills in brown hachures and contours, another printed in five colours, and a third showing distinctly the boundaries of all civil parishes. The department has likewise had in hand since 1898 a 4-mile map (1 : 253,440) of Great Britain, which is mainly intended to show five classes of roads. Taken as a whole, these Ordnance maps may fairly challenge comparison with the maps of any other country in the world; and if the hill hachures of the 1-inch maps are not quite satisfactory, this deficiency is in a large measure compensated for by the presence of absolutely trustworthy contours (see *Report on the Ordnance Survey*, annually presented to Parliament, and Colonel Sir J. Farquharson in the *Geographical Journal*, xv., 1900).

The famous *Carte de France de l'État-major* (1 : 80,000) was completed in 273 sheets in 1880. It has served as a basis for a *Carte de la France* on a scale of 1 : 100,000, published by the Service Vicinal, and of a general map on a scale of 1 : 200,000, in 81 sheets, which is printed in colours and was completed in 1888. Meanwhile the question of producing an entirely new map of France was referred to a committee, presided over by General De la Noir, in 1897; and if the recommendations of this committee are carried out, the result will be a map equal in accuracy to the British Ordnance Survey map, and possibly superior to it in attractiveness. There is to be an entirely new cadastral survey, connected with the triangulation of France. These cadastral plans are to be reduced to a scale of 1 : 10,000, or, in the case of mountain regions, of 1 : 20,000, and upon them the features of the ground are to be inserted by means of contours at intervals of 5 metres. Ultimately these *minutes* are to be published on a scale of 1 : 10,000, as also a general map of the whole country on a scale of 1 : 50,000. This latter is to be printed in colours, and the hills are to be shown by clearly marked contours and shading in chalk. Hachures are to be discarded, mainly owing to the great expense involved.

For the greater part of Germany there are now available maps on a scale of 1 : 25,000—*Messtischblätter*, called *Positionblätter* in Bavaria. Most of these are merely plane-table sections, with contours sketched in. The older among them leave very much to be desired on the point of fidelity and artistic finish, but those of later date exhibit much improvement, as, for instance, the kingdom of Saxony (since 1879), the grand-duchy of Baden (since 1876), and more especially the new topographical map of Württemberg. This last is a reduction of the cadastral survey on a scale of 1 : 2500; and the features of the ground are shown by contours based upon 300 to 800 measured altitudes to each square mile, and shading in chalk. The older maps of the separate states have now been nearly superseded by the new *Karte des Deutschen Reiches* in 674 sheets (610 published), on a scale of 1 : 100,000. This is an excellent map of its kind, engraved on copper, the hills being shown by hachures. The Prussian Government, moreover, acquired in 1874 Reymann's *Spezialkarte von Mittel-Europa*, on a scale of 1 : 200,000, which will ultimately consist of 796 sheets. A new topographical map (1 : 200,000), printed in three colours, was begun in 1900.

The *Spezialkarte* of Austria-Hungary, on a scale of 1 : 75,000 (763 sheets), was completed in 1889 and published in heliogravure. This map is based upon triangulation and cadastral surveys, where available, but it was produced far too rapidly to meet modern requirements as to accuracy, and in 1896 the director of the military geographical establishment at Vienna, Field-Marshal von Steeb, initiated what may be called an "epoch of exact measurements." The new map will be based upon a primary triangulation completed in 1890, and upon 11,610 miles of spirit-levelling. The cadastral plans are to be reduced to a uniform scale of 1 : 25,000, and the necessary details filled in with the aid of a plane-table and a tacheometer. A photogrammeter is to be used only in mountain districts. The hills are to be hachured, and the whole of the survey is to be completed in 75 years. The Austrian Government has its *Generalkarte von Mittel-Europa* (a very useful map, in 283 sheets), on the same scale as Reymann's map (1 : 200,000), but covering a different area, including nearly the whole of the Balkan Peninsula.

The mountainous nature of Switzerland has always challenged the skill of the cartographer to give it true expression, and certainly among the maps produced in this Alpine region there are several which claim a prominent place on account of their truth to nature. Whether the maps of the new Topographical Atlas of Switzerland—the so-called Siegfried Atlas, in 552 sheets—will universally be recognized as one of the most successful efforts of which the cartographic art is capable, may well be doubted. The maps constituting that atlas are the plane-table sections from which Dufour's famous map of Switzerland (1 : 100,000) was produced. They are on a scale of 1 : 25,000 for the hills and plains, and of 1 : 50,000 for the Alpine regions; they show the hills by contours drawn at intervals of 10 or 30 metres, and are printed in many colours. Lovers of maps will do well to study some of the so-called "Relief Karten" of the different cantons, which claim to delineate the ground in such a way as to give the impression of a relief.

The new survey of Belgium was completed in 1872, and there have now been published the plane-table sections (*planchettes*) on a scale of 1 : 20,000, and a "Carte topographique de la Belgique," on a scale of 1 : 40,000. The Netherlands likewise have long since published their topographical maps, on scales of 1 : 25,000, 1 : 50,000, and 1 : 200,000.

Germany.

Austria-Hungary.

Switzerland.

Belgium and Netherlands.

Denmark since 1890 has completed its *Generalstabens Kaart*, on a scale of 1:100,000, as also plane-table sections (*Maalebordsblade*), on a scale of 1:20,000. A *Generalstabens Kaart* of Jutland, 1:40,000, is approaching completion. The *generalstabenskart* of Sweden (1:100,000) is still in progress. It only embraces the country to 65° N., and is to consist of 234 sheets. The northern kingdom (*Karta öfver Norra Suerige*) has been mapped on a scale of 1:200,000. In the sister kingdom of Norway a topographical map, on a scale of 1:100,000, is in progress, in 354 sheets. Neither the *Amtskarter* (1:200,000) nor the *generalkart* of southern Norway (1:400,000) have yet been completed.

Proceeding into southern Europe, we find that a plane-table survey on a scale of 1:20,000 has been in progress ever since 1870, but that of the map of Spain in 1080 sheets (1:50,000), which has been in progress since 1884, only about 117 sheets had up till 1901 been published by the Depósito de la Guerra. Meanwhile reference may be made to B. F. Coello's *Atlas de España* (1848-90), the maps in which are on a scale of 1:200,000. Portugal has completed her *Charta chorographica* (1:100,000, 37 sheets) since 1856. In Italy a *Carta del Regno d'Italia* (1:100,000) and *Tavolette rilevate* (1:25,000 and 1:50,000) have been in progress since 1873. The former will consist of 277 sheets.

Greece, although the most ancient seat of civilization in Europe, is still dependent upon foreigners for its maps, among which the *Carte de la Grèce* (1:200,000), from rapid surveys made by General Palet in 1828, was published in a new edition in 1880.

A similar map, mainly based upon surveys made by Austrian officers and revised by Henri Kiepert (1:300,000), was published by the Military-Geographical Institute of Vienna in 1885. Far superior to these preliminary maps are the *Karten von Attika*, based upon careful surveys made by Prussian officers, and published by Curtius and Kaupert on behalf of the German Archaeological Institute in Athens. It is not long since the inhabitants of the Balkan Peninsula were indebted to foreigners for such maps as they made use of. This is the case no longer, for the kingdom of Servia has been surveyed (1880-91) by officers of the General Staff, and the map, on a scale of 1:75,000, has been published; whilst the triangulation was begun in Rumania in 1874, and a topographical survey in 1878. The results are being published on scales of 1:10,000 and 1:200,000. For the greater part of our knowledge of the topography of the Balkan Peninsula we are, however, still indebted to Austrian and Russian officers. The work of the former has already been referred to. The Russians in 1877-79 triangulated and surveyed a great part of the country, and the maps published include one of Turkey in Europe, 1:420,000 (1879-84), a map of Bulgaria and eastern Rumelia, 1:210,000 (1880-83), with contours at intervals of 70 feet, and a map of the eastern part of the Balkan Peninsula, 1:126,000 (1883). In 1899 a map of Turkey in Europe (1:218,000) was published by the Turkish General Staff, and there is some talk of beginning a regular survey.

Of Russia in Europe only the more densely peopled governments have been surveyed in the manner of other European countries, while for vast territories we have as yet only so-called "military surveys," or even mere itinerary surveys, the interior details being filled in from information collected on the spot. The most readily available map of the whole country is the 10-verst map (1:420,000) known as General Strelbitzki's,

and published 1865-80. A 3-verst military topographical map (1:126,000) now embraces the whole of western Russia, with Poland, and seems ultimately to be designed to be extended over the whole empire. Of this map 507 sheets have been published. It is engraved on copper, the hills are hachured, and on the sheets recently published contours at intervals of 70 feet are indicated. Certain governments—Moscow, Kief, Kaluga, &c.—have been published on a scale of 1:84,000, whilst Finland, as far as 61° N., was re-surveyed in 1870-95, and a map on a scale of 1:42,000 is approaching completion. Surveys in Asiatic Russia are conducted by the topographical departments organized at Tiflis, Orenburg, Tashkent, Omsk, and Yakutsk; and that of Tiflis deserves credit for having produced a 5-verst map of the Caucasus from actual surveys made since 1866, which answered general requirements, but was found so defective in the mountain regions that a new and more accurate survey was begun in 1886. The maps of other parts of the empire are on too small a scale to be styled "topographical." Among them may be mentioned, however, the maps of Orenburg (1858-79), Ferghana (1882), western Siberia (1880), and Lake Baikal (1886), all on a scale of 1:420,000. A map of the whole of western Siberia (1:680,000) was published in 1880-85, and one of the whole of Asiatic Russia (1:4,200,000) in 1883.

In Asiatic Turkey several districts of historical interest have been surveyed by foreign associations, and surveys have likewise been made in the interest of railways, but there is no such thing as a general survey carried on under the direction of the Government. Of this part of the world our maps, such as the Russian general map (1:630,000, published 1880-85), or the various maps by the late Dr H. Kiepert (for instance, western Asia Minor, 1:250,000, published in 1890), still remain compilations from materials very widely differing in value. A new map (1:210,000) of Turkey in Europe, based upon the Austrian map, has been published by the Turkish General Staff. Of Cyprus an excellent map on a scale of 1 mile to the inch, from surveys by Major H. (afterwards Lord) Kitchener, was published in 1884.

In the case of Persia we are still dependent upon compilations produced by the Russian and the Anglo-Indian Governments, such as the map by Colonel Sir T. H. Holdich (Simla, 1897), or the Russian Staff map (1:840,000), published in 1886.

British India, including Ceylon, can boast of a survey which in most respects is quite equal to those of most of the European states. The surveys are made on various scales, according to the necessities of the case or the nature of the country, and they are extended as occasion offers beyond the boundaries of India proper. Apart from plans of towns and villages on a large scale, the survey department publishes topographical maps of the provinces and native states on a scale of 1 inch to the mile, and the more generally useful *Indian Atlas* on a scale of 4 miles to 1 inch, which includes Ceylon and the Malay Peninsula, and will ultimately consist of 177 full sheets, of which 120 have now been published. The sheets of this atlas are kept up to date, and re-engraved as the results of fresh surveys become available.

In Siam a regular survey, initiated by Mr J. M'Carthy, a former official of the Indian Survey, has been begun (see *Surveying in and Exploration in Siam*, published by the Royal Geographical Society). In French Indo-China a cadastral survey has been in progress since 1881, whilst the Bureau Topographique has published a general map of Indo-China in 45 sheets (1:200,000, 1895), as also separate maps of the provinces of Tongking, Annam, and Cochin-China, on a scale of 1:500,000.

In China we are still largely dependent upon the labours of the Jesuits during the 18th century, and native maps of the interior.

China. The results of the coast surveys and of numerous local surveys will be found embodied in Baron F. von Richthofen's *Atlas von China* (1:750,000; Berlin, 1890), and in Bretschneider's *Map of China* (1:4,600,000), a new edition of which appeared at St Petersburg in 1896. Japan may boast of a regular survey department originated by Europeans and successfully carried on by natives. The primary triangulation was completed in 1880, and in addition to maps on a large scale, there are in course of publication an agronomical map (1:100,000) and geological maps (1:200,000 and 1:400,000).

Of Java we possess an excellent topographical map, completed in 1887 (1:100,000). A similar map has been in progress for Sumatra since 1883, whilst the maps of the remaining Dutch Indies are still based almost exclusively upon flying surveys. For general purposes J. N. Stenfort's and J. J. ten Siethoff's *Atlas der Nederlandsche Bezittingen in Oost-Indië*, of which a new edition has been in progress since 1900, may be consulted with confidence.

In Africa regular surveys up till now only extend over a small proportion of its vast area. In Egypt excellent work is done by a survey department in charge of Major H. G. Lyons,

Africa. R.E., which has published provincial irrigation maps (1:100,000), and has extended its operations into the Egyptian Sudan. Algeria and Tunis have been in course of survey since 1868. The topographical map is being published on a scale of 1:50,000, in addition to which there is a *carte de reconnaissance* on a scale of 1:200,000. Eritrea, the Italian colony on the Red Sea, has been regularly surveyed since 1884, and the results have been published on scales of 1:50,000 and, as a *carta dimostrativa*, 1:250,000 (16 sheets, 1897-1900). In Madagascar a regular survey has been begun by the French. In British South Africa a careful triangulation has been carried far into Bechuanaland, but as yet there are no comprehensive regular surveys, and maps are therefore mostly compilations from the plans prepared by the surveyors-general of the various colonies. Amongst these may be mentioned the map of the police districts of Cape Colony (1:627,800, 1887), Jeppe's *Map of the Transvaal* (1:476,000; Winterthur, 1899), Herfst's official *Kaart van de Oranje Vrijstaat* (1:460,000, 1890), Stanford's *Map of Mashonaland and Rhodesia* (1:1,000,000, 1900). In other parts of Africa explorations and partial surveys are carried on with considerable vigour, but the time seems to have arrived now for organizing at least a reconnaissance survey embracing the entire continent, which, in the opinion of so competent a judge as Colonel Sir T. Holdich, might be carried on at no greater expense than is involved now in numerous exploratory expeditions, and certainly much more efficiently.

What has been said of South Africa applies in an almost equal degree to the Australian colonies. In all of these cadastral surveys conducted by surveyors-general have been in progress for many years past, as also trigonometrical surveys (West Australia excepted), whilst the publication of parish and township or county maps keeps pace with the settlement of the country; but none of the colonies is as yet in possession of a topographical map equal in accuracy to similar maps published in Europe. Among more general maps may be mentioned those of Queensland (4 miles to the inch, 1897-99), New South Wales (8 miles to the inch, 1898), Victoria (1:443,520), South Australia (1:1,100,000, 1894) and West Australia (1:560,000, 1897).

In America, Canada and the United States take the lead in the production of topographical maps. The surveys in Canada are carried on by the Commissioners of Crown Lands in

Canada. Quebec, the Dominion Land Office (which lays out townships as in the United States, but with greater accuracy), the Surveyor-General's office attached to the Department of the Interior, and the Geological Survey. The last publishes its regular service maps on a scale of 4 miles to an inch, and reconnaissance or preliminary maps on half that scale. The maps of the Surveyor-General are on various scales (1:40,000, 1:190,000, &c.), and the photographic apparatus is successfully employed in the Rocky Mountain surveys. Among more comprehensive maps is one of the north-western part of the Dominion (3 miles to the inch, 1898), and another of the Yukon districts (1:380,000, 1898). The older maps are kept up to date.

In the United States the topographical maps produced since 1882 by the U.S. geographical surveys supersede all older maps, including the very imperfect ones of the Land Office. They are based upon a triangulation by the U.S. Coast and Geodetic Survey, and the details are considered sufficient to admit of the selection of general routes for railways and other public works. The maps of the more densely peopled parts of the Union are published on a scale of 1:62,500 (1 inch to the mile), and those of the remainder of the country on half that scale. The hills are shown by contours.

The survey progresses at the rate of about 40,000 square miles annually. There are, of course, many maps of the separate states, based on older surveys, as also a general map by H. Gannett and H. King (1:2,500,000; Washington, 1900). Maps of the islands of Cuba and of Puerto Rico were published in 1898 by the War Department on a scale of 1:250,000.

In Mexico the surveys are in charge of a Comisión Geográfica-exploradora attached to the Secretaría de Fomento, but up till now only about fifteen sheets of the *Carta general de la República*, on a scale of 1:100,000, have been published. There is also a *Carte general* of the state of S. Luis Potosi (1:250,000, 1894) and one of the environs of Puebla (1:20,000). These maps are excellent of their kind, but the slow progress of their publication is to be regretted. None of the other states of America can be said to possess a topographical survey department organized on a comprehensive basis. In the Argentine a geographical institute was established in 1879, but neither Seelstrang's *Atlas* (1892) nor Hoskold's *Mapa topografica* (1:2,000,000, London, 1895), which were published by it, nor any of the numerous provincial maps, are based upon scientific surveys. In Brazil little or nothing is done by the central government, but the progressive states of São Paulo and Minas Gerães have Comissões Geográficas e Geológicas charged with the production of detailed topographical maps. In Chile a Comisión Topografica was appointed as long ago as 1848, but the map produced under its auspices by Prof. A. Pissis (1:250,000, 1870-77) leaves much to be desired. A proposal for a cadastral and topographical survey made in 1895 by M. A. Bertrand has not as yet been acted upon. A *Mapa del Peru* based upon explorations made by A. Raimondi, 1850-69, has been in course of publication at Paris since 1889 on a scale of 1:500,000. Most of our maps are all dependent upon partial exploration, and it is satisfactory in these circumstances that the Service Géographique of the French army should have commenced (in 1900) the publication of a map of the whole of America on the scale of 1:1,000,000. It may also be mentioned that the same department is publishing a map of Asia on the same scale, and that the British Intelligence Department has in hand a like map of Africa. Thus the proposal of Prof. Penck to produce a map of the whole world on a scale of 1:1,000,000 will be realized, at least in part.

The publication of maps on smaller scales than those enumerated above, as also of maps for special purposes,—physical, political, or historical,—has, as a rule, been left to private firms, among whom Perthes in Germany, Hlyn in Russia, Hölzl in Austria, Hachette in France, Bartholomew, Philip, and Stanford of the United Kingdom, and the Matthews-Northrup Company in the United States, are the best known.

HYDROGRAPHIC SURVEYS.

Hydrographic surveys have been in progress since the early Middle Ages, but even now only a portion of the world's coastlines have been surveyed in a definite manner. Much of this work has been done by the survey departments of the different states concerned, but the British Hydrographic Office may justly claim the credit of having contributed the lion's share of the work lying outside the limits of civilized states, and British Admiralty charts (see CHARTS) are consequently most in demand throughout the world. Great Britain has taken the lead in those deep-sea explorations which reveal to us the configuration of the sea bottom, and enable us to construct charts of the ocean bed corresponding to the contoured maps of dry land yielded by detailed topographical surveys.

For geological maps, see GEOLOGY.

HISTORY OF MAPS.—The development of cartography since the time of the revival of Ptolemy has been set forth in the most brilliant manner by Nordenskiöld in his *Facsimile-atlas till Kartografens äldsta historia, innehållande af bildningar af de viktigaste Kartor tryckta före år 1600* (Stockholm, 1889). Other collections of reproductions of old and rare maps have been prepared by Dr. K. Miller (*Die ältesten Weltkarten*, Stuttgart, 1895, which only contains maps not influenced by the ideas of Ptolemy), Gabriel Marcel (*Reproductions de Cartes et de Globes relatives à la découverte de l'Amérique du XI^e au XVIII^e Siècle*, Paris, 1893), E. H. Coote (*Remarkable Maps of the XVth, XVIth, and XVIIth Centuries, reproduced in their original size*. I.-II., published by F. Müller, Amsterdam, 1894-97), and *Bibliotheca Lindesiana*, with facsimiles of the "Harleian" and other Dieppe maps of the 16th century. The large maps of Mercator, found anew in Breslau; the map of Europe, 1554; of Great Britain, 1564; and the map of the world, 1569, were published in facsimile in 1891 by the Berlin Geographical Society; and we owe an excellent synopsis of all known terrestrial and celestial globes to Matteo Fiorini (*Sfere terrestri e celesti di Autore italiano oppure fatte o conservate in Italia*, Roma, 1899).

The old "compass" charts have attracted the attention of

**Central
and South
America.**

students. So long as maritime cartography was confined to the Mediterranean and its immediate environment, and there was no practical need for determining the relation of the longitudinal axis of this sea to the circumference of the whole earth, nautical geography was satisfied with the registration of the distance in *miglia* between two coast points, and entered in the valuations in the sheets of the map. After numerous measurements Prof. Wagner has come to the conclusion that the *miglia*, in terms of which distances were measured on the old nautical maps, amounted to only about 1250 metres, *i.e.*, 230 metres less than the Roman mile. He further concludes that this small nautical mile reaches back a long way beyond the year A. D. 1000, and is therefore much older than the oldest nautical maps extant, and that in all probability we have here a measure handed down from antiquity and continued in use among the mariners. On the other hand, on the Pisan map (of the 13th century) the Roman mile of 1480 metres was applied to the measurement of the Atlantic seaboard. The smaller sea mile ($=\frac{2}{3}$ of the nautical mile) has in the Frisian waters maintained its validity to the present day. Obviously the Mediterranean maps are much older than the maps of the Atlantic coasts. But, without taking in hand the task of reduction, the ancient cartographers joined together the different sheets of the Mediterranean and the Atlantic into a collective representation, not troubling their minds about the error thus originated. The false orientation of their maps, shown especially in the primary orientation line from west to east, does not, however, proceed from the magnetic misdirection; but there are typical errors demonstrable in the representations of the Mediterranean such as may be found in Ptolemy himself, a fact pointing also to the connexion between Ptolemy and the nautical maps. Thus Ptolemy places Rhodes and Argos on the same parallel of latitude; Mount Athos and Cape Malea on the same meridian. These errors appear also after 1318 on the maps of Vesconte. The projection, however, employed by Ptolemy is not applied in the Italian nautical maps. It is impossible to draw over these nautical maps either the equidistant azimuthal projection or the Mercator's projection. The only network of degrees capable of being brought into conformity with these maps is that of an oblong plane-chart. This fact serves to confute the often uttered but never proven assertions that Henry the Navigator had already introduced graded maps, and so had substantially advanced the development of cartography. After the investigations made down to this date, it may be taken as authenticated that the mediæval nautical maps were first designed in Italy, in the land where navigation attained its highest development, and that we are not, as in his great work, *The Periplus*, Nordenskiöld has endeavoured to maintain, to look for the origin of these topographical maps among the Catalonians. The two oldest maps of the world, designed in Catalonian style, which only again became known in modern times, are the production of an Italian, Angelino Dalorto, whence it may be concluded that Catalonian cartography received its first impulses from Italy.

Many old nautical maps have been republished, such as those by Th. Fischer (*Sammlung mittelalterlicher Welt- u- See Karten—*“A collection of maps of the mediæval world and nautical maps”; Venice, 1886); K. Kretschmer (*Atlas zur Entdeckung Americas—*“Atlas illustrating the discovery of America,” Berlin, 1892); G. Marcel (*Choix de Cartes et de Mappemondes des XIV^e et XV^e Siècles—*“A selection of maps, and maps of the world of the 14th and 15th centuries,” Paris, 1896); and Nordenskiöld (*Periplus*, Stockholm, 1897). In addition to these collections, there are single maps published in geographical works and maps published separately in great number, not to mention that all the original works preserved in libraries have not yet been made fully known. It is therefore impossible to give a list of them here, or to supplement lists already published.

For a fairly complete list of modern maps of all parts of the world, we refer the reader to Mr J. G. BARTHOLOMEW'S “Mapping of the World” (*Scottish Geographical Magazine*, 1890 and 1891); for reports on the progress of cartography, to the *Geographisches Jahrbuch*, published by Perthes of Gotha, and for announcements of new publications to the *Geographical Journal*.

(S. R.; E. G. R.)

Maracaibo, capital of the state of Zulia, Venezuela, South America, on the western shore of Lake Maracaibo. It is one of the most important and most progressive cities in the republic, with a population of over 35,000 inhabitants. The bar which closes the gulf will not allow vessels drawing more than 12 feet to cross, but inside the bar there is a depth of 30 feet and more close to the town. Maracaibo maintains valuable commercial relations with foreign markets and with the in-

terior, and is the port of transit for goods intended for Colombia. It is the starting-point also for passenger and freight steamers and the railway lines of the Trujillo and Táchira sections of the state of Los Andes. The most important buildings are the public market, the executive mansion, legislative palace, municipal buildings, the Baralt theatre, university, new gaol, and six churches. There is a dockyard for the construction of sailing vessels. The town is equipped with electric lighting, telegraphs, telephones, tramways, &c. The import duties collected in the year ending 30th June 1896 amounted to £252,769, the imports of domestic products, salt, &c., for same period amounting to £86,736. The amount of coffee exported in 1896 was 28,211 tons, and in 1900, 20,050 tons. The export of hides is rapidly increasing, amounting in 1900 to 34,793 hides, besides 121,392 goatskins. Cocoa, fustic, dividivi, sugar, and copaiba are the chief of the remaining exports. The imports in 1898 amounted to £196,787, and exports to £842,600. In 1898 there entered 302 foreign vessels of 29,220 tons.

Máramarossziget, a corporate town of Hungary, with 15,210 inhabitants in 1891, and 17,445 in 1901. Among its educational establishments are a law academy, a state upper school for girls, &c. It is an important centre for the timber industry, with large steam mill, saw-mills, furniture factories, &c.

Maranhao, or MARANHAM, a state of north-east Brazil, with a coast-line of about 300 miles, in which the Atlantic receives the waters of six large rivers, all navigable by steamers. Its area covers 177,566 square miles. The population in 1872 was 359,010, and in 1890 it was 459,040. The capital, San Luis, is a finely-built city of 38,000 inhabitants. Other towns are Caxias (24,000), Alcantara (15,000), Carolina (10,000), Vianna, Grajahu, Itapicuru-mirim, and Turyassu.

Marañon. See AMAZON.

Marash (Assyrian *Maras*, Roman *Germanicia*, Byzantine *Murasion*), the chief town of a sanjak of the same name in the Aleppo vilâyet of Asiatic Turkey, altitude 2600 feet, situated north of the Jihún river, at the foot of Mount Taurus. The sanjak lies almost wholly in Mount Taurus, and includes the Armenian town of Zeitún. Marash is prosperous, and has a large trade in Kürd carpets and embroideries. The climate is good, except in summer. Of the population (40,000), about half are Armenians. There are a college, churches, and schools belonging to the American mission, and a Jesuit establishment. Marash occupies an ancient site on which “Hittite” inscriptions have been found. It was seized by the Crusaders after their march across Mount Taurus, became an important town of Lesser Armenia, and was taken by the Seljúks in 1147. In the 16th century it was added to the Osmanli empire by Selim I.

Marathon.—The tumulus or “Soros” at Marathon was excavated by M. Stais in 1891 and 1892. A slight previous excavation had brought to light some prehistoric implements, and so it was supposed that the mound had no connexion with the battle; but it has now been discovered that the presence of those prehistoric things was accidental. Underlying the mound was found a stratum about 85 feet long by 20 broad, consisting of a layer of sand, above which lay the ashes and bones of many corpses; together with these were the remains of many lecythi and other vases, some of them contemporary with the Persian wars, some of them of much earlier style, and probably taken in the emergency from neighbouring cemeteries. It is conjectured with some probability that a large vase containing ashes may have been used as the burial urn of one of the Athenian generals who fell. There was also, in

the middle of the stratum, a trench for funeral offerings about 30 feet by 3; it contained bones of beasts, with ashes and fragments of vases. There can therefore be no doubt that the tumulus was piled up to commemorate the 192 Athenians who fell in the battle, and that it marks the place where the carnage was thickest. A selection from the contents of the tumulus has been placed in the National Museum at Athens.

See *Ἀρχαιολογικὸν Δελτίον*, 1891, pp. 67 sqq. (E. GR.)

Marbella, a town and seaport of Spain, on the Mediterranean coast, in the province of Malaga. The town is well built, with clean, regular streets. An old castle crowns the height above, and the parish church has been restored. The local industries include the manufactures of alcohol, porcelain, and sugar, besides founding, and lead and iron mining. The port admits vessels drawing 18 to 20 feet; but there is good anchorage in deep water about half a mile from shore. There is a pier 1050 feet long, with a railway for bringing down and loading ores, and a lighthouse. Fish, grain, raisins, figs, cork, and iron ore are exported, but the trade is not of great extent. Population about 10,000.

Marblehead, a town of Essex county, Massachusetts, U.S.A., on a peninsula on the east side of Salem harbour on the north shore of Massachusetts Bay. The principal occupation of the permanent inhabitants is the manufacture of shoes. The town has become a popular summer resort and summer home for people of Boston. It has a public library, reading-room, and art gallery. Population (1890), 8202; (1900), 7582, of whom 973 were foreign-born.

Marburg, the second town in the Austrian duchy of Styria, a German enclave in a Slovene district. Population, with suburbs (1900), 24,501, German and Catholic, excepting 16 per cent. Slovenes and 1 per cent. Protestants. The garrison numbers 1343 men.

Marburg, a town of Prussia, province of Hesse-Nassau, on the right bank of the Lahn, 60 miles north of Frankfort-on-Main by the railway to Cassel. It is the seat of a university with (1900) 1184 students and 93 professors. A new villa quarter has grown up at the south foot of the castle hill. In the years 1873-91 a university building of sandstone was erected in the Early Gothic style. In 1884 the "Teutonic" house was converted into the zoological and mineralogical institutes of the university. The Lutheran church was restored in 1893. The university library contains about 160,000 volumes. The castle was restored in 1866-84; it contained the collections of the Hessian Historical Society. There are further a new post office (1882-84), various scientific institutes belonging to the university, an agricultural school, and a botanical garden. The industries include tanning and manufacture of machinery, pottery, tobacco, and toys. Population (1885), 12,668; (1900), 17,527.

March, a market town in the Isle of Ely parliamentary division of Cambridgeshire, England, 14 miles north-west by north of Ely; a junction station on the Great Eastern and Great Northern Joint railway. There is a public hall (1895). Population of parish (an urban district, 1894) (1891), 6988; (1901), 7565.

Marches, The, a territorial division of Italy, bordering on the Adriatic, and lying between Abruzzi on the S. and Emilia on the N. It embraces the provinces of Ancona, Ascoli-Piceno, Macerata, and Pesaro and Urbino, with an area of 3763 square miles, and a population of 983,670 (1881), and 1,064,749 (1901). Its principal crops are wheat, maize, wine, and tobacco. Except building

stone and sulphur, there are no minerals of value. The silk industries, making of strawplait and straw hats, rearing of silkworms and cocoons, with some sugar refining, tobacco, terra-cotta, and paper manufacture, brickworks, and iron-works, furnish the chief occupations of the people, next after agriculture and pastoral pursuits. The principal towns are Ancona (which is the chief seaport), Pesaro, Macerata, Urbino, Jesi, Ascoli, Camerino, Fano, Fermo, Fabriano, Recanati, and Senigallia. This division belonged down to 1860 to the Papal States.

Mardin, the chief town of a sanjak of the same name in the Diarbekr vilâyet of Asiatic Turkey, and a military station, situated on the Diarbekr-Mosul road. Half of the population, 12,000, are Christian. During the Armenian massacres of 1895 Mardin was attacked by Kurds, who were driven off by the garrison. It is the seat of an American mission, with church, schools, and medical officer.

Maree, Loch, one of the most beautiful of Scottish lakes, situated in Gairloch parish, Wester Ross. It is 32 feet above sea-level, $12\frac{3}{4}$ miles long, and from 3 furlongs to $2\frac{1}{4}$ miles broad, with a general depth of 360 feet. Skirted by lofty mountains, it contains twenty-seven islands, and is drained by the river Ewe. The fish are salmon, sea-trout, yellow trout, and char.

Margate, municipal borough, seaport, and market-town in the Isle of Thanet division of Kent, England, 4 miles west of North Foreland, and 90 miles by rail east of London. The old pier is used chiefly by fishermen and colliers; the landing-place has received several additions. Municipal offices have been presented to the town, and a theatre erected. The town has grown largely, especially in the part called Cliftonville, on the eastern side. There are electric trams running between Margate, Broadstairs, and Ramsgate. Dane Park (33 acres) was presented to the town in 1898. Population (1891), 18,662; (1901), 23,057. The visiting population in summer is very numerous. WESTGATE-ON-SEA, 2 miles west by south and practically a suburb, has a station on the South-Eastern and Chatham railway. It attracts a somewhat higher class of visitors than Margate. Population, 3000. BIRCHINGTON, a little farther to the west, is also a growing resort.

Margherita Maria Teresa, OF SAVOY (1851 ———), dowager-queen of Italy, daughter of Ferdinand, duke of Genoa, and of Elisabeth of Saxony, was born at Turin on 20th November 1851. Until eight years of age she lived with her mother, the widowed duchess of Genoa, at Stresa, on Lago Maggiore, but in 1859 returned to Turin, occupying a small apartment in the royal palace. Educated simply under the care of a Viennese governess, she took little part in court life until her marriage. Gifted with beauty and great personal charm, she acquired widespread popularity, and exercised her duties as princess royal with unflinching tact. Shortly after the occupation of Rome in 1870 she, with her husband, the crown prince, took up her residence in the Quirinal, where she continued to reside throughout the reign of King Humbert. A few months after the accession of her husband to the throne in January 1878 an attempt upon his life, committed at Naples by a lunatic named Passanante, produced a deep impression upon her mind, and, though she displayed the utmost fortitude at the moment, left for some years unpleasant traces upon her nervous system. An exemplary wife and devoted mother, she combined with these qualities a full perception of her rights and duties as queen, and ever discharged with assiduous alacrity the functions of her royal station. Thoroughly conversant with Latin,

Greek, and music, speaking several modern languages with fluency, widely read, and keenly interested in all manifestations of art, Queen Margherita holds a foremost place among the many distinguished women of the house of Savoy. (See also HUMBERT.)

Mariana, or MARIANNE ISLANDS. See MICRONESIA.

Marianao, a residential suburb on the shore of Cuba, to the west of the city of Havana, with which it is connected by means of a steam tram. Population (1899), 5416.

Maria Theresiopel. See SZABADKA.

Mariazell, a village and place of pilgrimage in the duchy of Styria, Austria. It is estimated that the shrine is visited by about 200,000 pilgrims annually. The principal resource of the inhabitants is the entertainment of visitors and the sale of rosaries, pictures, medals, and other souvenirs. Population (1890), 1116; (1901), 1341.

Marienbad, a celebrated watering-place in Bohemia, Austria. The permanent population in 1890 was 2119, and in 1900, 4588, mostly Catholic and German. The public buildings now include two hospitals for the poor, a convalescent home, a Russian church, a synagogue, the *Stadthaus* (containing the post and telegraph offices, the custom-house, a concert and ball room, a restaurant, and reading and assembly rooms), new bathing establishments, &c. It is visited annually by about 17,000 patients.

Marienberg, a town of Germany, 16 miles south-east of Chemnitz, in the circle of Zwickau, kingdom of Saxony, on the Flöha-Reitzenhain railway. It has a central school, a non-commissioned officers' school, and a preparatory school; and the industries comprise wool-spinning, flax-dressing, the making of lace, toys, and cigars, and silver-mining. Population (1890), 6300; (1900), 7108.

Marienburg, a town of Prussia, province of West Prussia, on the Nogat, an eastern arm of the Vistula, crossed here by a fine railway bridge (1892), 32 miles by rail south-east of Danzig. It is famous for the great castle and fortress of the Teutonic order. Its newer buildings embrace a couple of churches and the post office (1894). It possesses an agricultural school, a seminary for male and another for female teachers, and a deaf and dumb asylum; its industries include saw-mills, flour-mills, factories for cotton and wool, potteries, machine-shops, wool-cleansing, brick-making, and breweries. Population (1885), 10,136; (1900), 10,732.

Marienerwerder, a town of Prussia, province of West Prussia, near the right bank of the Vistula, 23 miles south of Marienburg by rail. The town was founded in the year 1233 by the Teutonic order. It has a cathedral of the same century, a triple Gothic edifice, restored in 1874; a (Gothic) town hall (1880); a Roman Catholic basilica (1858); a non-commissioned officers' school; a monument of the war of 1870-71 (1897); an archæological collection; and a seminary for female teachers. The industries include iron-foundries, saw-mills, breweries, and printing works. Population (1885), 8079; (1900), 9685.

Marietta, a city of Ohio, U.S.A., capital of Washington county, on the Ohio river, at the mouth of the Muskingum, in the south-eastern part of the state, at an altitude of 600 feet. It has a large river commerce, and is entered by four railways, the Baltimore and Ohio South-Western, the Cleveland and Marietta (part of the Pennsylvania), the Toledo and Ohio Central, and the Ohio and Little Kanawha. It has iron-works, saw-mills, and agricultural implement works. It is the seat of

Marietta College, a non-sectarian institution, founded in 1835, which had, in 1899, 18 instructors and 198 students, 72 of whom were women. The limits of the city were enlarged in 1890 by the addition of Harmar. Population (1890), 8273; (1900), 13,348, of whom 679 were foreign-born and 361 were negroes.

Mariinsk, a district town of Russia, West Siberia, government of Tomsk, on the bank of the Kiya river, 147 miles by rail east of Tomsk. It is built of timber, but has a stately cathedral and a town hospital. Its inhabitants, 8300 in 1897, live by agriculture, small tanneries, and soap-works, and especially by the currying trade. It is an entrepôt for the gold mines, and a centre from which the miners start in summer.

Marine Insurance. See INSURANCE.

Marines, formerly (1694) styled mariners, are sea soldiers—that is, troops appropriated and specially adapted to the requirements of maritime war. This force is in origin, use, and application peculiarly British. The only other nation possessing a special force discharging exactly similar functions is the United States.

The origin of the marine force was an Order in Council 1664, directing "1200 Land souldgers to be forthwith rayzed to be in readiness to be distributed in His Majesty's fleete prepared for sea service." This body was named the "Admiral's regiment." At this period land warfare had developed a system, and was waged by men organized, disciplined, and trained. Sea warfare was left "to every man's own conceit." War-ships were built to be manned in a hurry, by "the press," when needed. Men were thus obtained by force and grouped without organization or previous training in ships. When no longer required they were turned adrift. The administration of England's fleet was "a prodigy of wastefulness, corruption, and indolence; no estimate could be trusted, no contract was performed, no check was enforced." Such officers as had been "bred to the sea seemed a strange and savage race." They robbed the king and cheated the seamen. As regards land force, it was a violation of the law to keep at home in the king's pay "any other body of armed men, save as a guard for the royal person." On the other hand, it was "illegal to land press men" in a foreign country, but soldiers "only required a little persuasion to land." Thus by thrusting into naval chaos and confusion a nucleus of disciplined, trained, and organized land troops, an expedient was found which offered a solution of the many political and administrative difficulties of the time. This "Admiral's regiment" was the germ which by a constant process of evolution during a period of over 235 years has produced not merely the marine forces, but the royal navy, organized, disciplined, and trained as it is to-day. In 1668 the experiment of the Admiral's regiment was extended. At a Council held "to discourse about the fitness for entering men presently for manning the fleete," King Charles II. "cried very civilly, 'If ever you intend to man the fleet without being cheated by the captains and pursers, you may go to bed and resolve never to have it manned.'" This seems to throw some light on the Council's order a few days later "to draw out and furnish such numbers of His Majesty's Foot Guards for His Majesty's service at sea this summer, as H. R. H. the Duke of York, Lord High Admiral of England, shall from time to time desire." The men were to be paid and accounted for by their own officers. This maritime force subsequently disappeared, but two new regiments of "marines" were raised in 1694, the House of Commons directing they "were to be employed in the service of the navy only." One regiment only was to be on shore at a time, and to be employed in the dockyards with extra pay. None of the officers were to be sea commanders, save two colonels. The intention was to make these regiments feeders for the navy, captains being ordered to report periodically "the names of such soldiers as shall in any measure be made seamen, and how far each of them is qualified toward being an able seaman." In 1697 these regiments were disbanded, but early in the reign of Queen Anne a number of regiments of marines were raised, and independent companies of marines were also enlisted in the West Indies. At the Peace of Utrecht (1713) the marines were disbanded, but reappeared in 1739 as part of the army; and in 1740 three regiments of marines were raised in America, the colonels being appointed by the Crown, the captains by the provinces. In 1747 the marine regiments were transferred from the control of the Secretary of War to that of the Admiralty, and the next year once more wholly disappeared on the Treaty of Aix la Chapelle (1748).

During the preceding period of fifty-four years the marine force appeared and disappeared with war. It was a military body, applied to naval purposes. Its main functions were threefold—(1) for fighting in ships; (2) for seizing and holding land positions necessary or advantageous to the naval operations of war; (3) for maintaining discipline of the ships, and by "expertness in handling arms to incite our seamen to the imitation of them." Incidentally the force came to be regarded as so good a feeder for the navy that Admiral Vernon (1739) urged "the necessity of converting most of our marching regiments into marines, and if, as they became seamen they were admitted to be discharged as such, that would make a good nursery for the breeding of them."

The organization of the force was purely military. Regiments were embarked in fleets, and distributed in the ships. The officers were interchangeable with those of the guards and line. John Churchill (afterwards Duke of Marlborough) and George Rooke (afterwards Admiral Sir George Rooke) were together at one time ensigns of marines. During this period the marines were never regarded as a reserve for the fleet. The navy in peace did without them. The necessities of maritime war demanded a mobile military force adapted to naval conditions and at naval disposal, and so in all naval operations during these eighty-four years the marines played a conspicuous part. The navy had been slowly groping towards a system. For example, sea officers had been granted a uniform, and a naval academy (1729) had been established for the education of young gentlemen for the sea service. But in its main features the navy remained in 1748 as it was in 1664. The sailor was kidnapped and forced into ships, to become an outcast when no longer wanted. The marine when not in a ship was comfortably housed and looked after by his officers in barracks on shore.

In 1755 the marine force once more reappeared under the Admiralty, and from that date its history has been continuous. But the regimental system was abandoned, and an entirely new principle of organization was applied. Companies were raised, and these companies were grouped into great depôts, called divisions, at Portsmouth, Plymouth, and Chatham. At these divisions this force could be increased and reduced at pleasure, without disturbing the basis of organization, and from them could be supplied as many or as few sea soldiers as fleets or ships needed, while preserving in the varying units so provided all the essentials of uniformity of system, drill, training, ties of comradeship, and *esprit de corps*. This force then and for ninety-eight years afterwards was the only continuously trained, disciplined, and organized fighting force placed by the country at the disposal of naval officers. On the establishment of this new marine force the purchase of commissions was abolished, but interchange with the army was for a time permitted. When embarked, marines were under the naval code of discipline; when on shore, under the marine Mutiny Act, identical with that of the army. When the seamen of the fleet mutinied at the Nore, at the close of the 17th century, and turned their officers out of the ships, the marines, undaunted, stood firm by theirs.

Mutiny lurked beneath the deck of many a ship before and long years after that dramatic event. The control of admirals and captains over their own men was precarious in the extreme. This was the natural result of the country's neglect of its seamen. The discipline of the fleet in those days rested on the firm bayonets of the marines. What England owes to them may be gathered from Lord St Vincent's recorded testimony: "There never was an appeal made to them for honour, courage, or loyalty, that they did not more than realize my highest expectation. If ever real danger should come to England, the marines will be found the country's sheet anchor." At his earnest solicitation the marines were made a royal corps in 1802. It is worthy of note that in those days of masts, yards, sails, and pure seamanship, this greatest of naval statesmen, this matchless naval strategist, whose practical experience of maritime war was unrivalled, strenuously advocated as the true policy for England what in these days of steam and mastless ships would be scouted and ridiculed. It was to make service afloat as marines a part of the duty of every regiment of the line in rotation.

Down to 1804 the marines were an infantry force; the improvement in artillery towards the close of the century had necessitated the occasional putting into the fleet of detachments of Royal Artillery. This, as regards gunnery duties in the fleet, was repeating on a smaller scale the expedient adopted in the time of Charles II. So much friction arose between the naval and the artillery officers that a special corps of Royal Marine Artillery was raised in 1804, on the recommendation of Nelson. This special corps fulfilled the expectations of its founders. It was charged with the care, equipment, and working of the larger ordnance

afloat and field guns ashore, and was employed also as a body of gunnery instructors to the fleet. In 1831, a certain number of naval officers being thought to be sufficiently trained in gunnery, this corps, of which Napier wrote, "Never in my life have I seen soldiers like the Royal Marine Artillery," was, without warning, abolished. Then the marine force ceased to be composed of two corps, artillery and infantry, and it reverted to a single one of infantry. Very soon afterwards, however, the Admiralty began to build up what they had so suddenly and ruthlessly destroyed, by ordering the conversion of one company of each infantry marine division into artillery. The number of these artillery companies gradually increased, and were grouped in a separate depôt. Just as the wars from Charles II. to George III. had demanded marines, so the Crimean war led to their increase. Thus in 1859 the artillery companies of marines were formed into a separate division, and in 1862 the old name of Royal Marine Artillery was restored.

The marines thus became once more and still remain two corps, the official designation of the whole being Royal Marine Forces. In 1855 the marine infantry corps became light infantry, and in 1869 the Woolwich division (added in 1805) was abolished; and more recently a marine depôt, as a feeder of the other divisions, was established at Walmer. The headquarters of the R.M.A. are at Eastney, Southsea. The divisions R.M.L.I. are at Gosport, Chatham, and Devonport. The uniform of the R.M.A. is blue with red facings, that of R.M.L.I. red with blue facings. The badge of both corps is the globe surrounded with the laurel wreath, with the motto "Per mare per terram." The Royal Marine Forces share with the 3rd Battalion Grenadier Guards, the East Kent Regiment (formerly the Buffs), and the Royal London Militia the privilege of marching through the City of London with colours flying, bands playing, and bayonets fixed. This is due to a common original association with the London train bands.

War Services.—To describe these would be to review the wars waged by England by sea and by land for over 200 years. In every sea fight, great or small, marines have taken part, and on every continent they have served in big and little wars, sometimes as part of the army, sometimes with naval contingents, sometimes alone. The varied nature of the work done by the marines afloat and ashore during the Napoleonic war may be shortly illustrated by quoting the record of war services of one single marine officer, who died wholly unnoticed within the memory of many men now living. His name was Nicolls, but in official or public regard it had no honoured place. "With 13 volunteers in a boat of the *Blanche* frigate, he boarded and captured on 3rd November 1803 the French armed cutter *Albion* from under the guns of Monte Cristi, San Domingo; in this action he was severely wounded by a musket ball, which, entering the abdomen and coming out at his right side, lodged in the arm. On board the *Standard* at the passage of the Dardanelles on 19th February 1807. On 26th June 1808, with a boat's crew he boarded and captured the Italian gunboat *Volfé* near Corfu. Present at the reduction of the island of Anholt in May 1809. Severely wounded at the attack on Fort Bowyer 15th September 1814. Was frequently employed in boat and battery actions. In 1808 was in a boat at the capture of a French brig; in 1804 he commanded the Royal Marines during the siege of Curaçoa, and for twenty-eight consecutive days was exposed to several attacks of the enemy. At the passage of the Dardanelles he captured the Turkish flag, and was honourably mentioned. In 1807 he was at the blockade of Corfu and the expedition to Egypt. In North America he raised and commanded a regiment of Indians, and was senior major of all the troops engaged in the attack on New Orleans in 1814. Was also governor of the islands of Anholt and Ascension. During the above service he had his left leg broken and right leg severely wounded, was shot through the body and right arm, received a severe sabre cut in the head, was bayoneted in the chest, and lost the sight of an eye in his 107th action with the enemies of his country. He was frequently mentioned in despatches, and received a sword of honour from the Patriotic Fund."

During the Crimean war, mortar-boat flotillas in the Baltic and Black seas were commanded and manned by R.M.A., while comrades in the same corps served with the Royal Artillery in the trenches before Sebastopol—a marine infantry brigade occupying the heights of Balaklava. During the Indian Mutiny marines (artillery and infantry) served with the Naval Brigade under Peel. In the China wars batteries and brigades of the marine force played a prominent part, and likewise were represented in all the Egyptian and Sudan campaigns, 1881 to 1898. In one action the R.M.A. gunners came to the relief of the Royal Horse Artillery when exhausted, and fought their guns; in another the R.M.A., out of the *débris* of the enemy's Krupp guns captured, built up one complete gun and fought it with effect; in the final campaign gunboats were brought up in pieces, put together, and fought by a detachment of the R.M.A.

In 1899 in the Boer war the marine artillery and infantry took part with the Naval Brigade, maintaining their historic

reputation, and at the battle of Enslin their losses were exceptionally severe.

Characteristics of Marine System.—The recruit first goes to the depot at Walmer, and is trained as a soldier before joining his division to complete instruction as a marine. His division is his permanent military home, from which he goes on service and to which he returns at its conclusion. Restrictions on marriage, necessary under the army system, are not necessary in the marine forces. The permanent home of the wife and family is not broken up by the marine going abroad; the wife thus can continue any local goodwill in any business her industry may secure. This fixed home enables a marine to learn a trade in the workshops of his division which supply the clothing, &c., to the corps. Marines are enlisted for 12 years, and if of good character they can re-engage to complete 21 years, entitling to pension. The periods of service abroad for marines are shorter (generally 3 years), but more constantly recurrent than for the army. The administrative, as distinct from the instructional, staff necessary for a marine division is more simple and less expensive than that of a numerical army equivalent expressed in regiments. The system of pay and accounts is also less complex. The following table shows the relative proportions of marine forces to the whole navy at different periods:—

Year.	Navy proper. Officers and Men.	Marines. Officers and Men.	Grand Total.	Maritime. Peace or War.	Percent. Marines to Total Forces.	Nature of Ships.
1805	90,000	30,000	120,000	War (Trafalgar)	25	Sailing.
1838	23,165	9,000	32,165		Peace	28
1858	40,219	14,919	55,138	27		Sailing with auxiliary steam.
1878	42,046	13,727	55,773	24		Steam with auxiliary sail.
1898	78,441 ¹	17,099	95,540	17		Steam and mast-less ships.

The above table indicates a gradual change in naval policy and practice as regards marines. It will be observed that, concurrently with the gradual disappearance of masts, sails, and yards, the proportion of marines has steadily declined. Down to very recent times the marine spent more time ashore than afloat. Now the reverse is the case. There are 10,806 afloat and only 7745 on shore, and the latter figure includes the whole of the administrative and instructional staff and all the recruits under training.

By the introduction of the Continuous Service Act, 1853, the blue-jacket was placed on exactly the same footing as the marine in respect of conditions of service and pension, and now the blue-jacket when not afloat is quartered in barracks. The main difference between the blue-jacket and marine is the dress and the pay. The blue-jacket is better paid than the marine. As regards opportunity of discipline, there is now no difference; and in short, all the reasons for the existence of a marine force have disappeared except as regards duties on shore incidental to naval operations of war, *e.g.*, the holding of ports and the seizing of minor positions necessary to prosecution of maritime war. The facts that modern ships cannot now as formerly carry a supernumerary force sufficient for such purposes, and are more dependent on fixed bases of supply and repair than in old days, point to a different method of using and applying the marine force to the sole purpose for which they are now necessary as a distinct branch of the naval service. If employed at the headquarters of a naval station, their efficiency as marines could be preserved by occasional embarkation of the officers and men in rotation. The substitution of marine for army garrisons at coaling stations would also relieve the army of a class of duties incidental to naval warfare which the marine force formerly performed, and which prejudicially affects the organization and arrangement of the army as a mobile field force.

Marine Corps, United States.—This is the oldest force in the American service. It was formed in 1775, and it has a history of brilliant services rendered by land and sea in all the wars of America since that date. The

headquarters of the corps are at Washington, and the strength of the corps was fixed by Act of Congress (3rd March 1899) at 211 officers and 5920 non-commissioned officers and men. Its organization and system are based on the British model, and the dress corresponds to that of the United States army. A brigade of three battalions served in the Philippines in 1899. (J. C. R. C.)

Marine Salvage. See SALVAGE.

Marinette, a city of Wisconsin, U.S.A., capital of Marinette county, on the shore of Green Bay, Lake Michigan, at the mouth of the Menominee river, in the eastern part of the state, at an altitude of 611 feet. It is opposite Menominee, Michigan, with which it is connected by bridges over the Menominee river. It has an excellent harbour, and a large lake commerce, principally in lumber and iron ore. It has three railways, the Chicago and North-Western, the Chicago, Milwaukee, and St Paul, and the Wisconsin and Michigan. Its manufacturing establishments consist in great part of saw, shingle, and planing mills, and paper and pulp mills. Population (1880), 2750; (1890), 11,523; (1900), 16,195, of whom 5542 were foreign-born. The death-rate in 1900 was 14.3.

Marino, a town of the province of Rome, Italy, on a spur (1422 feet) of the Alban hills, 15 miles south-east of Rome. It occupies the site of the ancient *Castrimœnium*. In the Middle Ages it was a stronghold, first of the Orsini, then of the Colonna. It has a cathedral, and possesses soap factories, ironworks, and tanneries, and is famous for its wine. Population, about 6000.

Mario, Giuseppe, COUNT OF CANDIA (1810–1883), Italian singer, the most famous tenor of the 19th century, son of General di Candia, was born at Cagliari in 1810. His career as a singer was the result of accidental circumstances. While serving as an officer in the Sardinian army he was imprisoned at Cagliari for some trifling offence. When his period of confinement was over, he resigned his commission. His resignation was refused, and he fled to Paris. There his success as an amateur vocalist produced an offer of an engagement at the Opera. He studied singing for two years under M. Ponchard and Signor Bordogni, and made his *début* in 1838 as the hero of Meyerbeer's *Robert le Diable*. His success was immediate and complete, but he did not stay long at the Opera. In 1839 he joined the company of the Théâtre Italien, which then included Malibran, Sontag, Persiani and Grisi, Rubini, Tamburini, and Lablache. His first appearance here was made in the character of Nemorino in Donizetti's *Elisir d'Amore*. He sang in London for the first time in the same year. His success in Italian opera far surpassed that which he had won in French, and in a short time he acquired a European reputation. He had a handsome face and a graceful figure, and his voice, though less powerful than that of Rubini or that of Tamberlik, had a velvety softness and richness which have never been equalled. Experience gave him ease as an actor, but he never excelled in tragic parts. He was an ideal stage lover, and he retained the grace and charm of youth long after his voice had begun to show signs of decay. He created very few new parts, that of Ernesto in *Don Pasquale* (1843) being perhaps the only one deserving of mention. Among the most successful of his other parts were Otello in Rossini's opera of that name, Gennaro in *Lucrezia Borgia*, Almaviva in *Il Barbiere di Siviglia*, Fernando in *La Favorita*, and Manrico in *Il Trovatore*. Mario made occasional appearances in oratorio, singing at the Birmingham Festival of 1849 and at the Hereford Festival of 1855, and undertook various concert tours in the United Kingdom, but his name is principally

¹ Includes 22,289 of the engineer branch providing the locomotion of modern ships—just as seamen from 1805–58 provided it for ships of the past.

"A VILLAGE SCENE." By JACOB MARIS.

associated with triumphs in the theatre. In 1856 he married Giulia Grisi, the famous soprano, by whom he had five daughters. Mario bade farewell to the stage in 1871. He died at Rome in reduced circumstances, 11th December 1883. (R. A. S.)

Marion, a city of Indiana, U.S.A., capital of Grant county, 67 miles north-east of Indianapolis, towards the north-eastern part of the state, on the Cleveland, Cincinnati, Chicago and St Louis, the Pittsburg, Cincinnati, Chicago and St Louis, and the Toledo, St Louis and Western railways, at an altitude of 811 feet. It is in an agricultural and natural gas region, and its manufacturing establishments include glass-works, flour-mills, and steel rolling mills. It is the site of a national soldiers' home. Population (1880), 3182; (1890), 8769; (1900), 17,337, of whom 564 were foreign-born and 650 were negroes.

Marion, a city of Ohio, U.S.A., capital of Marion county, a little north of the centre of the state, on the Cleveland, Cincinnati, Chicago and St Louis, the Hocking Valley, the Columbus, Sandusky and Hocking, and the Erie railways, at an altitude of 979 feet. It is in a rich agricultural region, and its manufactures consist mainly of agricultural tools and machinery. Population (1880), 3899; (1890), 8327; (1900), 11,862, of whom 782 were foreign-born and 112 were negroes.

Maris, Jacob (1837–1899), Dutch painter, first studied at the Antwerp Academy, and subsequently in Hébert's studio during a stay in Paris from 1865 till 1871. He returned to Holland when the Franco-Prussian war broke out, and died there in August 1899. Though he painted, especially in early life, domestic scenes and interiors invested with deeply sympathetic feeling, it is as a landscape painter that Maris will be famous. He was the painter of bridges and windmills, of old quays, massive towers, and level banks; even more was he the painter of water, and misty skies, and chasing clouds. In all his works, whether in water or oil-colour, and in his etchings, the subject is always subordinate to the effect. His art is suggestive and realistic rather than decorative, and his force does not seem to depend on any preconceived method, such as a synthetical treatment of form or gradations of tone. And yet, though his means appear so simple, the artist's mind seems to communicate with the spectator's by directness of pictorial instinct, and we have only to observe the admirable balance of composition and truthful perspective to understand the sure knowledge of his business that underlies such purely impressionist handling. Maris has shown all that is gravest or brightest in the landscape of Holland, all that is heaviest or clearest in its atmosphere—for instance, in the "Grey Tower, Old Amsterdam," in the "Landscape near Dordrecht," in the "Seaweed Carts, Scheveningen," in "A Village Scene" (see Plate), and in the numerous other pictures which have been exhibited in the Royal Academy, London, Edinburgh (1885), Paris, Brussels, and Holland, and in various private collections. "No painter," says M. Philippe Zileken in his work on the modern painters of the Netherlands, "has so well expressed the ethereal effects, bathed in air and light through floating silvery mist, in which painters delight, and the characteristic remote horizons blurred by haze; or again, the grey yet luminous weather of Holland, unlike the dead grey rain of England or the heavy sky of Paris."

Maritime Province (*Primorskaya Oblast*), a province of Russia, representing a strip of territory along

the Pacific coast of Russian Manchuria and East Siberia, from the Korean town Kyghen-nu (42° 38' N.) to Bering Strait. Area, 715,990 square miles. The population in 1898 was 228,824, of whom only 73,455 were women, and 50,585 lived in towns, while the remainder were distributed as follows:—South Usuri, 98,711 (and 29,185 at Vladivostok); North Usuri Cossacks, 20,917. The population of the Khabarovsk district is 12,692 (and 15,082 in the town of Khabarovsk); of Udscoi district, 10,032 (and 5726 at Nikolaievsk); Okhotsk district, 4615 (and 199 at Okhotsk town); Petropavlovsk district (Kamchatka), 8010, and 398 at the town of same name; Ghizhiga district, 7571; Commander Islands, 653; Anadyr district (Chukchi Land), 12,425; mining district, 2608. The Russians number 128,946; the natives (Chukchi, Tungus, Orochons, Golds, &c.), 44,705; the Koreans, both Russian and Korean subjects, 23,279; the Chinese, 29,284 (only 453 women); the Japanese, 2030; various, 580. The yearly increase during the years 1895–97 was from 2438 to 3170. Commander Islands—Bering, Myednyi (Copper), and Tyuleniy—are important as the centre for seal-hunting. In the years 1871 to 1891 an average of 30,000 seals (occasionally 50,000) were killed on these islands every year. But as the American and British hunters kill the seals at distances of from 30 to 150 miles from the islands, the number of seals obtained on Commander Islands fell to an average yearly catch of only 13,000.

Hunting remains an important branch of income, the yearly items being about 5800 sable furs, 15 beaver, 2700 fox, 65,000 squirrel, 1830 bear, and so on. Fishing (salmon and other fish) is considerable in Kamchatka, the Sea of Okhotsk, and along the Manchurian coast, as also in the Amur, the Usuri, and other rivers. Active measures were taken in 1883–97 for increasing the Russian population in the South Usuri district, the result being that 29,093 immigrants, chiefly Little Russian peasants, transported on board ships from Russia, settled there, although 501 of them chose to return to Russia. Besides, 3788 Cossacks from the Don and Orenburg (1746 women) came to settle among the Usuri Cossacks. The immigration of Koreans to the Usuri region, which was especially strong after the famine in Korea in 1869, has now been stopped by law. Agriculture is gradually developing in the South Usuri region, where 127,600 acres were under grain crops in 1897, but it shows slow progress among the Cossacks, who had only 18,900 acres under crops. It is estimated that there were in the same year 39,215 horses, 58,070 horned cattle, 1250 sheep, 168,700 reindeer, and 32,130 trail-dogs in the Maritime Province. Gold-mining has been started in the province on the Amguñ, a tributary of the Amur, and from 264 lb in 1889 it attained 4660 lb in 1897. Coal is found on the Muravioff-Amursky peninsula, near Vladivostok, as well as in Kamchatka. Maritime trade has been on the increase, the number of ships visiting Nikolaievsk, at the mouth of the Amur, being 86 (chiefly Japanese), and Vladivostok, 246 (chiefly German), in 1897. The total imports were: 14,340,000 roubles in 1896, and 6,299,000 in 1897 (mostly for the Crown). As to river steamers, 120 were afloat in the same year in the system of the Amur, and this number has increased since. But when the Amur is frozen, there is no communication between Khabarovsk and Blagovestchensk or Nikolaievsk, except on sledges along the river, or on horseback when the ice is not safe. Roads exist only in the South Usuri district. At present a railway line runs from Vladivostok to Nikolsk (69 miles), and thence to Khabarovsk along the right bank of the Usuri (400 miles). At Nikolsk begins the Manchurian railway, which, notwithstanding the delay occasioned by the Boxer rising, is ready now as far as Transbaikalia, and is open for service and partly for private traffic.

Markby, Sir William (1829—), English jurist, the fourth son of the Rev. William Henry Markby, recorder of Duxford St Peter's, was born at Duxford, Cambridge, in 1829. He was educated at Bury St Edmunds and Merton College, Oxford, where he took his degree in 1850. In 1856 he was called to the bar, and in 1865 he became recorder of Buckingham. In 1866 he went to India as judge of the High Court of Calcutta. This post he held

for twelve years, and on his retirement was appointed Reader in Indian Law at Oxford. In 1892 he was a member of the Commission to inquire into the administration of justice at Trinidad and Tobago. Besides *Lectures on Indian Law*, he wrote *Elements of Law considered with reference to the General Principles of Jurisprudence*. The latter, being intended in the first place for Indian students, calls attention to many difficulties in the definition and application of legal conceptions which are usually passed over in text-books, and it ranks as one of the few books on the philosophy of law which are both useful to beginners and profitable to teachers and thinkers. In 1897 appeared *The Indian Evidence Act, with Notes*. Sir William Markby also contributed to the law magazines articles on *Law and Fact*, *German Jurists and Roman Law*, *Legal Fictions*, &c., several of which are embodied in the later editions of the *Elements*. He was made D.C.L. of Oxford in 1879, and K.C.I.E. in 1889.

Market.—This term is used in two well-defined senses:—

(1) It means a definite place where traders who are retail sellers of a specific class of commodity or commodities are in the habit of (a) awaiting buyers every day in shops or stalls; or (b) proceeding to the place in question on specified days at more or less frequent regular intervals. Covent Garden market for fruit and flowers, and Leadenhall market for meat and poultry, are good examples in London of the kind of institution included in class (a). They are a very ancient economic phenomenon, dating from the earliest period of the development of organized communities of human beings, and in general characteristics have changed little since they began to exist.

Markets of the type of class (b) are also of very ancient origin (see *Fairs*, vol. viii.), but inasmuch as they are constituted essentially by the presence of persons, many of whom assemble from various places outside the place of meeting, they were capable of a little more development than those belonging to class (a), owing to increased facilities for locomotion. The nature of an ancient market of class (a), whithera citizen, say of Athens, or his chief slave, proceeded daily to make household purchases, differs little from the group of shops visited by the wives of the poor or less wealthy citizens of modern states. In many places abroad, and not a few in England, actual markets still exist. It may be said that the huge collections of shops, such as the various co-operative stores, are only a revival of the old "market-place," with its shops or booths gathered round a central area, adapted to the needs of modern big cities.

(2) The term "market" has come to be used in another and more general sense in modern times. According to Jevons, a market is "any body of persons who are in intimate business relations, and carry on extensive transactions in any commodity." He adds that "these markets may or may not be localized," and he instances the money market as a case in which the term "market" denotes no special locality. As a rule, however, most of the business of a market is transacted at some particular place, such as the London Stock Exchange, the Baltic, the Bourse of Paris, the Chicago "Wheat-pit." Even in the case of the London money market, merchants still meet twice a week at the Royal Exchange to deal in foreign bills, although a considerable part of the dealings in these securities is arranged daily at offices and counting-houses by personal visits or by telegraphic or telephonic communication. The markets in any important article are all closely interconnected. The submarine cable has long ago made Chicago as important an influence on the London corn market as Liverpool, or rather both London and Liverpool affect and are simultaneously affected by Chicago and other foreign

markets. In like manner the Liverpool cotton market is influenced by the markets in New Orleans and other American cities separated from it widely in space. In a minor degree the dealers in all places where a cotton market exists affect the bigger markets to some extent. What is true of the cotton market is also true to some extent of all markets, though few markets are so highly organized or show such large transactions as that for cotton. Among other markets of the first class may be mentioned those for pig-iron, wheat, copper, coffee, and sugar. There are many articles the markets for which are of considerable dimensions at times, but are of an intermittent character, such as the London Wool Sales, which take place now in five "series" during the year. Formerly the number of "series" was four.

CHARACTERISTICS OF MARKETS.

The conditions required in order that the operations of a trading body may display the fully-developed features of a modern market, whether for commodities or securities, are:—

- (1) A large number of parties dealing.
- (2) A large amount of the commodities or securities to be dealt with.
- (3) An organization by which all persons interested in the commodity or security can rapidly communicate with one another.
- (4) Existence and frequent publication of statistical and other information as to the present and probable future supply of the commodity or security.

The movements which take place in prices in any market, whether fully organized or not, depend largely on changes of opinion among buyers and sellers. The changes of opinion may be caused by erroneous as well as by correct information. They may also be the result of wrong inferences drawn from correct information. In markets for commodities of the first importance such as wheat, cotton, iron, and other articles which are dealt in daily, the state of opinion may vary much during a few hours. The broad characteristics of markets of this class are similar. There is a tendency in all of them to show phenomena of annual periodicity, due partly to the seasons, the activity of certain months being in normal years greater in the case of any given market than that of other months. This tendency was always liable to be interfered with by the special forces at work in particular years; and the great increase in the facilities of communication between dealers by telegraph, and of transportation of commodities between widely distant points, which was one of the marked features of the development of the economic organism in all actively commercial countries during the last thirty years of the 19th century, has still further interfered with it. Nevertheless, a tendency to annual periodicity is still perceptible, especially in markets for produce of the soil, the supply of which largely depends on the meteorological conditions of the areas where they are grown on a scale sufficient to furnish an appreciable proportion of the total produce.

Periodicity of another kind known as "cyclic," and due to a different set of causes, is believed to exist by many persons competent to form a judgment; but although the evidence for this view is, in the opinion of the present writer, very strong, the theory expounding it is not yet in a sufficiently advanced state to admit of its being regarded as established.

PHENOMENA OF MARKETS.

Bagehot said of the money market that it is "often very dull and sometimes extremely excited." This classical

Movements of prices.

Cycles.

description of the market for non-specialized wealth applies to a large extent to all markets.

Every market is at every moment tending to an equilibrium between the quantity of commodities offered and that of commodities desired; supposing equilibrium to have been attained in a given market, and that for some appreciable period it is not disturbed, the price for the commodity dealt in in the market will remain practically unchanged during that period. Not that there will be no transactions going on, but that the amounts offered daily will be approximately equal to the amounts demanded daily.

We have briefly described the statical condition of a market; we must now briefly examine its dynamics. Disturbance may take place through a change in—

- (1) Supply, or opinion as to future probable supply.
- (2) Demand, or opinion as to future probable demand.
- (3) In both simultaneously, but such a change that demand is increased or decreased more than the supply, or *vice versa*.

A moderate disturbance caused by one of the above changes, or a combination of them, will produce an immediate effect on the price of the commodity, which again will tend to react on both the supply and the demand by altering the opinions of sellers and buyers. If no further change tending to disturb the market takes place, the market will gradually settle down again to a state of equilibrium. But if the disturbance has been considerable, a relatively long time may elapse before the market becomes quiet; and very likely the level of price at which the new equilibrium is established will be very different from that ruling before the disturbance set in. Further scientific investigation of the dynamics of a market is in any case very difficult, and is impossible without a complete analysis of the statical condition, such as is found at length in the text-books of mathematical economics; but it is possible to describe briefly certain dynamical phenomena of markets which are of a comparatively simple character, and are also of practical interest.

Every great market is organized with a view not merely to the purchase and sale of a commodity at once, or "on the spot," but also with a view to the future requirements of buyers and sellers. This organization arises naturally from the necessities of business, since modern industry and commerce are carried on continuously, and provision has to be made for the requirements, say, of a spinning-mill, by arranging for the delivery of successive quantities of cotton, wool, or silk over a period of months "ahead." In the case of cotton "forward deliveries" can be purchased six or seven months in advance, and the person who undertakes to deliver the cotton at the times stated is said in the language of the market to "sell forward." If the quantity of cotton produced each year were always the same, no very remarkable results would follow from this mode of doing business except the economy resulting to the spinner from not being compelled to lock up part of his capital in raw material before he could use it. But as the cotton and other crops vary considerably from year to year, some curious consequences follow from the practice of "selling forward." The seller, of course, makes his bargain in the belief that he will be able to "cover" the sale he has made at a profit—that is, he hopes to be able to buy the cotton he has to deliver at a lower price than he undertook to deliver it at. If so, all is well for both parties, for the buyer has had the advantage of having insured a supply of cotton. But supposing something has happened to raise the price considerably, such as a great "shortage" of the crop, the

seller may lose. If a great many other persons have taken the same mistaken view of the probabilities of the market, a condition of things may arise in which they may be "cornered."

A "corner" in an exchangeable article is an abnormal condition of the market for it, in which, owing to a serious miscalculation of probable supply, many traders who have made contracts to deliver at a certain date are unable to fulfil them. In most cases the fact that the market is "oversold" becomes known some time before the date for the completion of the contracts, and other traders take advantage of the position to raise the price against those who are "short" of the article. A corner is therefore usually a result of the failure of a speculation for the fall. Theoretically a trader who has undertaken to deliver 100 tons of an article, but cannot, after every endeavour, obtain more than 90 tons, could be made to pay his whole capital in order to be relieved from the bargain. In practice he gets off more easily than this. Frequently when many traders have sold largely "forward" other traders deliberately try to use that position as a basis for creating a "corner." Generally, however, they only succeed in causing great inconvenience to all parties, themselves included, for as a rule they are only able to make the "corner" effective by buying up so much of the article that when they have compelled their opponents to pay largely to be relieved of contracts to deliver, they are left with so big a stock of the article that they cannot sell it except at a loss, which is sometimes big enough to absorb the gain previously secured. In the case of very small markets "corners" may be complete, but in big markets they are never complete, something always happening to prevent the full realization of the operators' plans. The idea of a "corner" is, however, so fascinating to the commercial mind, especially in the United States, that probably no year passes without an attempt at some operation of the kind, though the conditions may in most cases prevent any serious result.

"Corners" have what is called a "moral" aspect. It is curious to note that the indignation of the "market" at the disturbance to prices which results from operations of this kind is generally directed against the speculators for the fall, while that of the public, including trade consumers, is directed against the operator for the rise. The operator for the fall, or "bear," is denounced for "selling what he has not got," a very inaccurate description of his action, while the "bull" or operator for the rise is spoken of by a much wider circle as a heartless person who endeavours to make a profit out of the necessities of others. From a strict ethical standpoint there is really nothing to choose between the two.

THE MONEY MARKET.

There is one market which presents features so peculiar a character that it is necessary to describe it more particularly than other phenomena of the kind, and that is the money market. The term money is here used to denote *non-specialized wealth*, a form of wealth which has existed from early times, but not in great abundance until within the last two or three hundred years. Immense wealth has existed in certain countries at various epochs, owing to the fertility of the soil, success in trade, or the plunder of other communities, and all states which have been great have at the time of their greatness possessed wealth; but the wealth which the countries, or a few fortunate individuals belonging to them, owned consisted largely of what is still called real property—that is, land and buildings—and of the produce of the soil or of mines. The balance consisted partly of merchandise of various kinds and shipping, and to a large extent of the precious metals,

in the form of coin or bullion, or of precious stones and jewellery. Where no settled government was established no one could become or remain very wealthy who was not in a position to defend himself by the strong hand, or allied with those who were; and as a rule the only people who could so defend themselves were possessors of large areas of rich land, who were able to retain the services of those who dwelt on it either through their personal military qualities or in virtue of habit and custom. The inhabitants of wealthy cities were able to protect themselves to some extent, but they nearly always found it necessary to ally themselves with the neighbouring land-owners, whom they aided with money in return for military support.

A money market in the modern sense of the word could only exist in a rudimentary form under these conditions. There was a sort of money market, for there was a changing rate of interest and a whole code of law relating to it (Macleod, *Banking*, 3rd ed. p. 174) in republican Rome; but although large lending and borrowing transactions were part of the daily life of the Roman business world, as well as of those of the Greek cities and of Carthage and its dependencies, none of these communities presented the phenomena of a highly organized market. Money-lending was also a regular practice in Egypt, Chaldea, and other ancient seats of civilization, as recent discoveries show. It was only in comparatively recent times, however, when Europe had formed itself into more or less organized states, with conditions fairly favourable to the steady growth of trade and industry, that organized money markets came into existence in places such as Venice, Genoa, Augsburg, Basel, the Hanse towns, and various cities in the Low Countries, Spain and Portugal, as well as in London. The financial strength of these rudimentary money markets was not very great, and as it depended a good deal on the possession by individuals of actual cash, the existence of these markets was precarious. "Hoarded ducats" were too often an attraction to needy princes, whose unwelcome attentions a rich merchant, even when an influential burgher of a powerful city, was less able to resist than the violence of a vulgar house-breaker, against whom strong vaults and well-secured chests situated in defensible mansions were a good protection. The necessitous potentate could often urge his desire for a "loan" by very persuasive methods. Occasionally, if his predecessors had acquired the confidence of the banking class sufficiently to induce them to place their cash reserves in one of his strong places "for safety," an unscrupulous ruler could help himself, as Charles II. helped himself to the stores of the London goldsmiths which were left in the Mint. The power of the banking class continued to grow, however, and a real market for money had come into existence in many cities of Europe by the middle of the 17th century. The Bank of England was founded in 1694. "Banks" of a sort had existed in various countries certainly since the beginning of the 15th century; and it is claimed for Child and Co. that they existed as a bank in 1559, and Martin's can trace their origin equally far as "goldsmiths." The Bank of Amsterdam was founded about 1614, and a bank was established in Barcelona in 1400 (Turner, *Bank of England*, p. 2); but until the 17th century it was difficult to distinguish merchants from bankers, who in England were usually known as goldsmiths. Readers who are interested in the early history of banking in London may be referred to Mr Hilton Price's *Handbook of London Bankers*, and Mr John B. Martin's *Grasshopper in Lombard Street*.

In the 18th century the "money market" consisted of the Bank of England and various banks and merchants, the distinction between the two being still not complete. Towards the end of that century arose an important

class of dealers in credit, the bill-brokers, and with their appearance the modern money market of London may be said to have assumed its present form, for though the process of development has not ceased, the changes have been of the nature of growth and not of the acquisition of new organs. The formation of joint-stock banks and discount companies, however, and the reconstitution of the Bank of England by the Act of 1844, exercised an important influence on the way in which the money market of London has developed. It must be explained that in the everyday talk of the City "the market" has a special meaning, by which only the banks and discount houses are denoted, as in the phrases constantly seen in the daily reports published in the newspapers towards the end of a quarter, "the market has to-day borrowed largely from the Bank of England," or, "the market was obliged to renew part of the loans which fell due to the Bank to-day." But this use of the term in a special sense, thoroughly understood by those to whom it is habitual, and resulting in no ambiguity in practice, is not in accord with the requirements of economic analysis. It may be as well to add that the charge for interest on loans and for the discount of bills is always quoted as a rate per cent. per annum, and the sum actually payable is arrived at by calculating the number of days during which the loan, or bill, runs.

The working organs of the money market of London at the beginning of the 20th century were:—

- A. (1) The Bank of England.
- (2) Banks, joint-stock and private, including several great foreign banks.
- (3) Discount houses and bill-brokers.
- B. (4) Certain members of the Stock Exchange.
- (5) Certain great merchants and finance houses.

The institutions included in group A are the most constantly active organs of the money market; those included in group B are intermittently active, but in the case of section (4), though their activity is greater at some times than others, they are never wholly outside the market. Even in the case of (5) a certain amount of qualification is needed, which is indicated by the fact that most of the great merchant houses are "registered" as bankers, though they do not perform the functions usually associated with that term in the United Kingdom. Several of the great houses were originally and still are nominally merchants, but are largely concerned with finance business—that is, with the making of loans to foreign governments and the issue of capital on behalf of companies. During the Boer war (1899–1902) their assistance was freely given to the British Government in order to provide funds for the military operations in South Africa. These powerful capitalists often have large amounts of money temporarily in their hands, and lend it in the money market or on the Stock Exchange; one or two of them are large buyers of bills from time to time, and generally the members of this group may be said to be in sufficiently close touch with the active organs of the money market to form part of it.

The actual working of the money market has been described by that original and powerful thinker Walter Bagehot in his *Lombard Street*, a work which has attained the rank of a classic. Most of what he said in 1873 is true now, but in certain minor respects developments have taken place, the most important being the greater extent to which money is "used up" every day, or rather every night. In Bagehot's time the discount houses only quoted "allowance" rates for "loans at call and short notice" based on the rate

The early money market.

The modern money market of London.

The working of the money market.

“allowed” by the banks for loans at seven days’ notice; but since then the bill-brokers have been obliged (1) occasionally to fix their terms independently of the banks, and (2) to “allow” a rate for “money for the night.” This latter practice became usual about 1888 or 1889. The change it introduced was not a vital one, but has some importance from the point of view of the historian. A good deal of the “money” thus dealt with is derived from the group of traders included in class (5). It is (a) money which is temporarily in the hands of houses or institutions which have just received subscriptions to loans or other capital offered to the public; (b) balances left temporarily with finance houses or banks on behalf of foreign governments or other parties who have payments to make in London. In the former case the “money” is almost invariably only available for a short time, probably only for a few days; in the latter case also it probably will be only available for a few days, but *may* be available for months. Money derived from either of these sources is usually to be had cheap, but is not in the slang of the City “good,” because it is uncertain how long loans at call obtained from either of them will remain undisturbed. Nevertheless there has been at times so much “money” of this fugitive character, and derived from such varied sources since about 1888, that its cheapness has been an attraction to the less wealthy bill-brokers, who have occasionally been able to go on using it profitably for many continuous weeks or even months in their business. The risk run by employing it is, of course, the certainty that it will be “called” from the borrower sooner or later, and probably at a time when it is very inconvenient to repay it. The more wealthy houses take money of this kind when it suits them, but never rely on it as a basis for business.

Since Bagehot wrote, the growth of the big joint-stock banks has been enormous, not so much through the increased business done by banks generally, though the expansion in banking has been considerable, as by the absorption of a great number of small banks by three or four large institutions (see BANKING). It will probably be found in the future that the growth of these large institutions will tend to facilitate combination for purposes of common concern among banks generally—*e.g.*, to support the Bank of England in maintaining its reserve, which is the sole reserve of all the banks, at a proper level, and thus render the money market more stable. Two or three of the banks have for a long time, owing to their large holding of bills, had much more influence than the Bank of England over the foreign exchanges, on which the foreign bullion movements chiefly depend; and since 1890 persons of weight in the joint-stock banking body have implicitly, though not explicitly, admitted a certain degree of responsibility in the matter on behalf of their institutions. It is, however, characteristic of British business arrangements that the question of the responsibility for the reserve of the Bank of England, the ultimate reserve of the whole country, is still in as nebulous a condition, so far as explicit acceptance of responsibility by any institution is concerned, as it was in 1870. There has been no improvement in theory, though in practice there has been real improvement, since Bagehot’s time.

The following is a statement of the total deposits of the joint-stock banks of the United Kingdom (with one or two unimportant exceptions), and of such private banks as publish accounts, for the end of December 1901 (not including the deposits of the Bank of England); with the cash in hand and money at call and short notice held by them at the same date (taken from the banking supplement of the *Economist* of 17th May 1902); with the figures for corresponding dates at the end of 1896 and 1891, the

reserve in the banking department of the Bank of England on 24th December 1901, 23rd December 1896, and 23rd December 1891, and the amounts cleared by the London Bankers’ Clearing House in 1901, 1896, and 1891.

Deposits.

Banks.	December 1901.	December 1896.	December 1891.
England and Wales . . .	£ 584,842,000	£ 495,233,000	£ 391,900,000
Scotland . . .	107,321,000	95,695,000	92,368,000
Ireland . . .	49,117,000	45,552,000	39,451,000
Total deposits	741,280,000	636,480,000	523,719,000

Cash in hand and at call.

Banks.	December 1901.	December 1896.	December 1891.
England and Wales . . .	£ 153,943,000	£ 115,870,000	£ 91,038,000
Scotland . . .	26,870,000	22,005,000	20,682,000
Ireland . . .	10,797,000	9,423,000	9,520,000
Total cash in hand and at call . . .	191,610,000	147,298,000	121,240,000
Reserve in the Banking Department of the Bank of England . . .	19,685,000	24,068,000	14,011,000
Amount of “paid clearing” of London clearing bankers . . .	9,561,169,000	7,574,853,000	6,847,506,000

With regard to the above figures, it may be pointed out that the proportion borne by the “cash in hand, &c.,” to the total deposits was 25·8 per cent. in 1901, 23·1 per cent. in 1896, and 23·1 per cent. in 1891. The proportion of the reserve of the Bank of England to the total deposits was 2·7 per cent. in 1901, 3·8 per cent. in 1896, and 2·7 per cent. in 1891. The last return in December always shows a reserve below the average for the year. Although the proportion as shown by the above figures is the same as in 1891, there has really been some improvement, because the statement of deposits in that year does not include many banks, now included, which did not publish balance-sheets in the former year. The earlier proportion was therefore really smaller than it appeared to be. The Bank of England’s average weekly reserve now is, moreover, much larger than it used to be before 1890. For 1889 the average weekly reserve was only £13,228,000, against liabilities probably nearly as great as those of 1891. (See BANKING.) Of the “cash in hand, &c.,” more than half, judging by the thirteen big banks whose accounts are analysed every month in *The Times*, must be in “cash in hand and at the Bank of England.” It is to be regretted that all banks do not give this item separately from “cash at call and notice.”

The discount houses, though an important body of institutions, are not of so much importance as they were before 1866, when they suffered a serious blow through the failure of “Overends,” from which as a body they have never fully recovered. The five large concerns which still exist are, however, very powerful, and exercise considerable influence on the market. They hold considerable quantities of bills at all times; occasionally their holdings are very large; but they turn out the contents of their bill cases readily if they think fit. Their business is different in practice from that of the smaller “bill-brokers,” who usually are what their name suggests, namely, persons who do not hold many bills, but find them for banks who need them, charging a small commission. The small bill-brokers borrow from the Bank of England much more freely than the big discount houses. The latter only “go to the bank” in ordinary times perhaps once or twice a year. During the South African war, which disturbed the money market very much, they obtained accommoda-

The discount houses.

tion from the Bank more frequently than usual. The small brokers almost always have to borrow from the Bank at the end of every quarter, when money is scarce owing to the regular quarterly requirements of business, and also, to some extent, because certain of the banks make it a practice to call in loans at the end of each month in order to show a satisfactory cash reserve in their monthly balance-sheet. This practice is not approved by the best authorities, for although it does no great harm in quiet times, the banks who follow it might find it difficult, or even impossible, to call in their loans in times of severe stringency.

Market Harborough, a manufacturing and market-town and parish in the Harborough parliamentary division of Leicestershire, England, 14 miles south-east of Leicester by rail, traversed by the Grand Union Canal. There are malt-houses and boot, shoe, and stay factories. The town is also an important hunting centre. Population of urban district (Market Harborough with Great and Little Bowden) (1891), 5876; (1901), 7735.

Markham, Sir Clements Robert (1830—), English traveller, geographer, and author, son of the late Rev. David F. Markham, canon of Windsor, and of Catherine, daughter of Sir W. Milner, Bart., of Nunappleton, Yorkshire, was born on 20th July 1830 at Stillingfleet, near York, and educated at Westminster School. He entered the navy in 1844, and was appointed naval cadet on board H.M.S. *Collingwood*. He served under Sir George Seymour on the Pacific station, became midshipman in 1846, and passed for a lieutenant in 1851. In 1850–51 he served on the Franklin search expedition in the Arctic regions, under Captain Austin. He retired from the navy in 1852, and in 1852–54 travelled in Peru and the forests of the eastern Andes. He visited South America again in 1860–61, in order to arrange for the introduction of the cinchona plant into India, a service of the highest value to humanity. In 1865–66 he visited Ceylon and India, in order to inspect and report upon the Tinnevely pearl-fishery and the cinchona plantations. On the Abyssinian expedition of 1867–68 he served as geographer, and was present at the storming of Magdala. In 1874 he accompanied the Arctic expedition under Sir George Nares as far as Greenland. In later years Sir Clements Markham travelled extensively over Europe, and also in western Asia and the United States. He also held various official and honorary positions at home. In 1855 he became a clerk in the Board of Control. From 1862–64 he was private secretary to Mr T. G. Baring, afterwards the earl of Northbrook. From 1867–77 he was in charge of the geographical department of the India Office. He was secretary to the Hakluyt Society from 1858–87, and became its president in 1890. From 1863–88 he acted as secretary to the Royal Geographical Society, and on his retirement received the society's gold medal for his distinguished services to geography. He was elected president of the same society in 1893, and took an active share in the work of the society and in increasing its usefulness in various direc-

tions. It was almost entirely due to his unwearied exertions, extending over several years, that the funds were obtained for the National Antarctic Expedition under Captain Robert Scott, which left England in the summer of 1901. He was president of the International Geographical Congress which met in London in 1895. Sir Clements Markham conducted the *Geographical Magazine* from 1872–78, when it became merged in the *Proceedings of the Royal Geographical Society*. Among his other publications may be mentioned the following: *Franklin's Footsteps*, 1852; *Cuzco and Lima*, 1856; *Travels in Peru and India*, 1862; *A Quichua Grammar and Dictionary*, 1863; *Spanish Irrigation*, 1867; *A History of the Abyssinian Expedition*, 1869; *A Life of the Great Lord Fairfax*, 1870; *Ollanta, a Quichua Drama*, 1871; *Memoir on the Indian Surveys*, 1871 (2nd ed. 1878); *General Sketch of the History of Persia*, 1873; *The Threshold of the Unknown Region*, 1874 (4 editions); *A Memoir of the Countess of Chinchon*, 1875; *Missions to Tibet*, 1877 (2nd ed. 1879); *Memoir of the Indian Surveys; Peruvian Bark*, 1880; *Peru*, 1880; *The War between Chili and Peru*, 1879–81 (3rd ed. 1883); *The Sea Fathers*, 1885; *The Fighting Veres*, 1888; *Paladins of King Edwin*, 1896; *Life of John Davis the Navigator*, 1889; also lives of *Admiral Fairfax*, *Admiral John Markham*, *Columbus*, and *Major Rennell*; a *History of Peru*; editions with introductions of twenty works for the Hakluyt Society, of which fourteen were also translations; sixty-seven papers in the Royal Geographical Society's *Journal*; the *Reports on the Moral and Material Progress of India for 1871–72 and 1872–73*; *Memoir of Sir John Harington* for the Roxburghe Club, 1880; the Peruvian chapters for Winsor's *History of America*, and the chapters on discovery and surveying for Clowes's *History of the Navy*. Sir Clements Markham was elected a Fellow of the Royal Society in 1873, and became an honorary member of the principal geographical societies; he was created C.B. in 1871, and K.C.B. in 1896; in 1874 he was created a Commander of the Portuguese Order of Christ, and a Chevalier of the Brazilian Order of the Rose; in 1898, Commander (first-class) of the Swedish Order of the North Star.

Marlboro, a city of Middlesex county, Massachusetts, U.S.A., in the central part of the state, with an area of about 22 square miles, diversified with hills and ponds, and traversed by the Fitchburg, and the New York, New Haven and Hartford railways. In 1900 there were 142 manufacturing establishments, with a capital of \$2,191,860, an average number of 2780 hands, and products valued at \$4,986,399. The chief industry is the manufacture of boots and shoes. Marlboro was formerly a town, but was chartered as a city in 1890. Population (1890), 13,805; (1900), 13,609, of whom 3311 were foreign-born.

Marlborough, a municipal borough and market town in the Devizes parliamentary division (since 1885) of Wiltshire, England, 11 miles south by east of Swindon by rail. Marlborough College is now divided into three schools, the upper, modern, and lower. In the upper a classical education, preparatory for the universities, is mainly given; in the modern, mathematics, science, and modern languages are specially taught, and there are separate classes for army and navy pupils. Foundation scholarships preserve the original purpose of the school—that it should be for the education of the sons of clergymen. Several important additions have been made to the school buildings, including a museum (1883), a handsome chapel (1886), north classrooms (1893), and a memorial reading-room (1900). In 1901 the number of scholars was 600. Population (1891), 3012; (1901), 3046.

Marlow, Great, a town and railway station in the Wycombe parliamentary division (since 1885) of Buckinghamshire, England, 5 miles north by west of Maidenhead, on the Thames, which is here crossed by a pretty suspension bridge. It formerly returned two members to Parliament, but in 1885 its representation was merged in that of the county. Since 1896 it has been governed by an urban district council. Population of urban district (created 1893) (1891), 4212; (1901), 4526.

Marmande, chief town of arrondissement, department of Lot-et-Garonne, 35 miles north-west of Agen, on railway from Bordeaux to Certe. The church, a Gothic edifice, dating in part from the 13th century, contains a fine 17th-century altar-piece and some good modern glass. Local institutions comprise the communal college, hospital, library, tribunal of commerce, and consultative chamber of agriculture. Brandy and liqueurs are manufactured, and there is considerable commerce in grain, flour, wine, hemp, and prunes. The town, which dates from the 6th century, suffered severely during the war of the Albigenes. In 1214, and again in 1219, it surrendered to the De Montforts, and on the latter occasion many of the inhabitants were massacred in cold blood. Population (1881), 6117; (1901), 9184.

Marmier, Xavier (1809–1892), French author, was born at Pontarlier in 1809. He had a passion for travelling, and this he combined throughout his life with the production of literature. After journeying in Switzerland, Belgium, and Holland, he was attached in 1835 to the Arctic expedition of the *Recherche*; and after a couple of years at Rennes as professor of foreign literature, he visited (1842) Russia, (1845) Syria, (1846) Algeria, (1848–49) North and South America, and numerous volumes from his pen were the result. In 1870 he was elected to the Academy, and he was for many years prominently identified with the Sainte-Geneviève library. He died at Paris in 1892.

Marne, a department of the north-east of France, watered by the Marne.

Area, 3168 square miles. The population, 429,494 in 1886, had increased to 432,850 in 1901. In 1899 the deaths, numbering 9559, exceeded the births, 9544, of which 950 were illegitimate; marriages numbered 3260. There were in 1896, 1042 primary schools, with 64,000 pupils, the illiterate forming 3 per cent. of the population. The area under cultivation in 1896 amounted to 1,910,193 acres, of which 1,336,888 acres were plough-land and 34,595 acres vineyards. The land in wheat in 1899 yielded the value of £1,186,000; rye, £440,000; barley, £251,000; oats, £260,000; mangold-wurzel, £136,000. Green crops (trefoil, lucern, and sainfoin) yielded £260,000, and natural pastures £380,000. Of the industrial cultures, beetroot, producing the value of £189,000, is alone worth mentioning. The vine, however, notwithstanding the very limited surface it covers, yet by virtue of the quality of its wine (champagne) returned in 1899 the value of £1,612,000. The live stock in 1899 numbered 48,300 horses, 119,990 cattle, 294,150 sheep, and 64,410 pigs. Agriculture is the main occupation of this department. There is some peat-cutting (1300 metric tons in 1898), and some mining of iron and limestone. The metallurgic production is inconsiderable. The textile industry, however, particularly that of wool, is in a very forward state around Reims, the department counting 8000 power-looms and 270,000 spindles. Châlons, the capital, had a population in 1901 of 21,487; Reims, 107,773.

Marne, Haute-, a department of the east of France, watered by the Marne.

Area, 2416 square miles. The population, 247,781 in 1886, had decreased to 224,888 in 1901. In 1899, out of 4157 births, 260 were illegitimate; there were 5058 deaths; marriages numbered 1563. There were in 1896, 850 primary schools, with 32,000 pupils, not more than 1 per cent. of the population being illiterate. The area under cultivation amounted in 1896 to 1,453,032 acres, 800,649 acres in arable land and 32,124 acres in vines. A large extent of the department is covered with wood. The wheat crop of 1899 amounted to the value of £987,000; oats, £593,000;

vines, 237,000; potatoes, £88,000; natural pastures, £280,000. In 1899 Haute-Marne owned 48,820 horses, 98,410 cattle, 122,330 sheep, and 99,900 pigs. The department possesses important iron mines, which in 1898 produced 147,000 metric tons. Its metallurgy (in a very forward state, especially around Langres) registered in 1898, 44,000 metric tons of cast iron, 67,500 tons of iron, and 32,400 tons of steel, of a total value of £975,000. The other industries are less important, the forges and blast furnaces consuming 6289 horse-power out of a total of 8697. Chaumont, the capital, had 14,622 inhabitants in 1901.

Marocco. See MOROCCO.

Marochetti, Carlo, BARON (1805–1867), Italian sculptor, was born at Turin in 1805. After studying under Bosio, he went in 1827 to France, and his statue of "A Young Girl playing with a Dog" won a medal in 1829 at Paris. His "Fallen Angel" was exhibited in 1831. In 1848 Marochetti removed to London, and there he lived till his death on 28th December 1867. Among his chief works were statues of Queen Victoria, Lord Clyde (the obelisk in Waterloo Place), Richard Cœur-de-Lion (Crystal Palace), Emmanuel Philibert (1833, Turin), the tomb of Bellini (Père la Chaise), and the altar in the Madeleine. His style was vigorous and effective, but rather popular than artistic. Marochetti, who was created a baron by the king of Sardinia, was also a Chevalier of the Legion of Honour.

Maros-Vásárhely, a municipality of Hungary, in the county of Maros-Torda, with 15,264 inhabitants in 1891 and 19,091 in 1901. It was once the capital of the "Szekelys" (Sicilians). In the beautiful Gothic Calvinist church, built about 1446, situated in the old fort, was held, in the presence of Prince John Sigismund, in the year 1571, the famous diet which, for the first time in Europe, enacted the perfect liberty of religion. In its Protestant college Farkas Bolyai, the celebrated mathematician, was a leader.

Marquardt, Joachim (1812–1882), German scholar, was born at Danzig, 19th April 1812. He studied at Berlin and Leipzig, held various educational appointments from 1833 onwards at Berlin, Danzig, and Posen, and became in 1859 head of the "gymnasium" in Gotha. His *Römische Staatsverwaltung* (1873–78) and *Privatleben der Römer* (1879–82), which formed a part of Mommsen and Marquardt's revised edition of Becker's *Handbuch der Römischen Alterthümer*, were widely recognized as valuable contributions to classical learning. He died at Gotha, 30th November 1882.

Marquesas Islands. See TAHITI.

Marquette, a city of Michigan, U.S.A., capital of Marquette county, on Marquette harbour, on the south shore of Lake Superior, in the upper peninsula, at an altitude of 621 feet. The city is irregularly laid out, is divided into eight wards, and is the terminus of branches of the Duluth, South Shore, and Atlantic railway. It is the principal shipping point for ports on the lower lakes, and for Pittsburg, Pa., of the iron ores of the Marquette district, the richest iron region in the world. For handling the ores cheaply many great ore docks have been constructed, by means of which railway cars are unloaded directly into the holds of vessels. There is also a large trade in lumber. Population (1890), 9093; (1900), 10,058, of whom 3460 were foreign-born and 62 were negroes. The death-rate in 1900 was 16.6.

Marrákesch, sometimes erroneously called Morocco City, the second imperial city of Morocco, lying at the foot of the Great Atlas, 96 miles east-south-east of Saffi. Scottish missionaries and a few European traders have become established here, but no other changes have taken place for centuries. Population, 50,000 to 60,000.

MARRIAGE.

I. UNITED KINGDOM AND EUROPEAN COUNTRIES.

SINCE 1883, when the earlier volume of this Encyclopædia (ninth edition) containing the article on marriage was published, few subjects have been more discussed and few branches of the law have undergone such significant changes. From that year itself dates the coming into operation of the Married Women's Property Act of 1882, the great charter which now regulates the position of married women in England in regard to their property and their contractual capacity generally. It was the outcome of a long struggle which led first to the Act of 1870, a tentative enactment passed to secure married women's earnings against appropriation by the husband, and in 1874 to an amending Act for the protection of the husband against debts of his wife contracted prior to the marriage, and ultimately, in 1882, to the complete emancipation of the wife's property from marital control (see more fully below). In the course of ten years English legislation in the matter of married women's property progressed from perhaps the most backward to the foremost place in Europe. By a curious contrast, the only two other European countries where, in the absence of a settlement to the contrary, independence of the wife's property is recognized, are Russia and Italy (Italian Civil Code, Art. 1425 *et seq.*).

Among other countries, in France a law of 1881 empowered the married woman to open a deposit account at the Post Office Savings Banks, but inasmuch as the husband can lodge a caveat to prevent withdrawal of the money, and can lay hands on the money as soon as an application is made by the wife to take it out, the protection is illusory. It must not, however, be supposed that the position of married women in France in respect of their property is abnormally hard. Their position is only regulated from a different point of view, and in several respects it is an exceptionally privileged one. It is mainly owing to this that progress, in the sense of the recognition of separate property, will probably be slower in France than elsewhere. Thus, though by ante-nuptial marriage contract the paraphernal system of emancipation of the wife's property may be secured, it is seldom resorted to, because in the absence of an ante-nuptial marriage contract—and in France, as elsewhere, marriage contracts are uncommon among the mass of the population—the wife is owner of one-half of all property saved or personal property acquired by succession or otherwise, after the marriage, by either husband or wife. The husband during coverture certainly has the absolute control of the whole of this joint fortune, but on dissolution of the marriage the half of it can be claimed by the wife or her heirs and assigns.

This system of community of property is engrained in French institutions and custom as the common law of the country, and there is no movement to follow the example of Italy and adopt the paraphernal system as the common law in its place. Among the French middle class the wife, owing to her ownership of half the fortune acquired by her husband, takes a more active part in his business life and holds a higher business status generally than she does in other countries. She is her husband's partner in all his enterprises, and has an equal interest with him in all their proceeds. Sometimes wonder is expressed that the bulk of French women seem so indifferent to agitation for an increase of their independence, but isolated cases of hardship are not considered a ground for altering a law on

which the whole social economy of the nation is based, and which gives the French married woman a position in her household and in her family surpassing in dignity and prestige that of women in any other country.

In Scandinavia there is a marked tendency towards contractual emancipation, but as yet it has not gone farther than the married woman's earnings. Sweden adopted a law on this subject in 1874, Denmark in 1880, Norway in 1888. Germany followed the Civil Code which came into operation in 1900 (Art. 1367), providing that the wife's wages or earnings shall form part of her *Vorbehaltsgut* or separate property, which a previous article (1365) placed beyond the husband's control. As regards property accruing to the wife in Germany by succession, will, or gift *inter vivos*, it is only separate property where the donor has deliberately stipulated exclusion of the husband's right.

In several other branches of the law of marriage the United Kingdom is not as much to the front. This applies to prohibition of marriage with a deceased wife's sister (see below), to breaches of promise of marriage, perhaps even to the facility generally with which marriage is contracted and the absence of specialized control through a civil authority which might introduce more order and system into the working of the chief social institution.¹ Still marriage holds its own, though severely criticized by different contemporary writers, and the number of those entering the state of matrimony does not diminish, in spite of warnings of its probable unhappiness. There is, in fact, no significant change in the proportion of those who marry to those who (acting on Mr Punch's advice) "don't." The following table shows that the tendency is to increase rather than diminish:—

Persons married in the United Kingdom—Annual Rates per Thousand of Population.

1890 . . .	14·5	1895 . . .	14·3
1891 . . .	14·6	1896 . . .	15·0
1892 . . .	14·5	1897 . . .	15·2
1893 . . .	13·9	1898 . . .	15·4
1894 . . .	14·2	1899 . . .	15·7

In other countries the aggregate experience of marriage seems no less favourable to it.

*Marriages in Chief Continental Countries—Annual Rates per Thousand.**

*Compiled from British official abstracts.

¹ The existing system of national registration was introduced by Lord John Russell's Act of 1836. Sir Spencer Walpole, in his *Life of Lord John Russell* (vol. i. p. 260), observes that "his own views were enlarged and strengthened by the experience of a long lifetime, and he lived to record his opinion that it will be a matter for consideration whether the future law, instead of recognizing the marriage registers of every Christian communion and every Jewish synagogue, should not be founded on the same principle as the laws of France and Italy, constituting civil marriages the only bond recognized by the State,

Here again the trend of the figures is towards increase. Comparing the British figures (which we must halve to bring them to the same term of comparison) with the Continental, Great Britain shows a fair average, higher than Scandinavia and lower than Germany, Austria, Hungary, and Russia.

In 1886 an Act was passed in the British Parliament to remove doubts which had been entertained as to the validity of certain marriages solemnized in England when one of the parties was resident in Scotland. In the same year an Act was passed extending the hours within which marriage may be lawfully solemnized from 8 A.M. to 12 to between 8 A.M. and 3 P.M. (For the Foreign Marriage Act of 1892, see below.) The Summary Jurisdiction (Married Women) Act of 1895 enabled a wife whose husband is convicted of an assault on her, or who has been deserted by him, or been obliged owing to his cruelty to live apart from him, to apply to the justices, who are empowered by the Act to make an order for separation and grant the wife the custody of children under 16 years of age. The justices may also make an order for payment by the husband to his wife of such weekly sum, not exceeding two pounds, as, having regard to the means both of husband and wife, they may consider reasonable. The Marriage Act, 1898, authorized the celebration of marriages in places of worship duly registered for the solemnization of marriages under the Marriage Act of 1836 without the presence of the registrar, on condition of their being solemnized in the presence of a person duly authorized by the governing body of the place of worship in question. It also made further provision for the due recording of all marriages in the general registers. Lastly, the Marriages Validity Act of 1899 removed doubts as to the validity of marriages in England on Irish banns and in Ireland on English banns. The next enactment will probably be one for the purpose of regulating the solemnization in England of marriages between English women and foreign men, which may be invalid in the country of the latter.

The property of married women is now governed in England by the Married Women's Property Act, 1882. Under the common law of England all the personal property which devolved upon or was acquired by the wife passed to her husband, who could, immediately on its falling into possession, deal with it as his own. He was even entitled to the rents and produce of his wife's real property. The wife could not bind herself by contract except in a few special cases (*e.g.*, if she carried on trade within the City of London). Even her personal wages and earnings could be lawfully appropriated by her husband. "The very being or legal existence of woman is suspended during her marriage, or at least it is incorporated and consolidated into that of her husband, under whose wing, protection, and cover she performs everything," wrote a learned commentator on the old law. The Court of Chancery, it is true, protected trust dispositions securing to the wife the use of her separate property, but this afforded no protection to the great mass of married women, who continued to be the victims of antiquated principles of the old law till 1870, when the legislature made the first great breach in it. Half measure though it was, it went, as we have seen, as far as, if not farther than, most Continental legislatures ventured to advance up to 1902. It excluded the husband from control over the wife's personal wages and earnings, and the investments of such independent wages and earnings, and by

and leaving to the parties concerned to add any religious ceremony or ceremonies they may think proper."

it contractual capacity to the extent of this independent property was necessarily by implication granted to her. The Act of 1882 was practically the extension of the operation of this Act from one kind of married women's property to the whole of it. The married woman thenceforth became capable of acquiring, holding, and disposing by will or otherwise of all her real or personal property, as if she were unmarried, and without the intervention of any trustee, and her contractual capacity and liability were extended to the whole of her separate property. She also became liable, like anybody else, to the bankruptcy laws. As a consequence of these provisions, investments standing in the wife's name are deemed to form part of her separate property till the contrary is proved, and she can transfer her stock and receive the dividends or interest of it on her sole signature. This is the *régime* under which she now lives in Great Britain and Ireland.

Scottish Acts (40 and 41 Vict. c. 29, and 44 and 45 Vict. c. 21) placed her in a similar but not identical position in Scotland. The Married Women's Property (Scotland) Act, 1881, does not, in fact, give the wife as much independence as the English Act of 1882. It extends the operation of a previous one of 1877, which secured to her the sole and exclusive disposal of her earnings, to personalty owned by her at the date of her marriage or which may come to her by bequest, but, while giving her the disposal of the income of it, it precludes her from assigning the prospective income and from disposing of the fund itself without her husband's consent.

There is an unfortunate omission in the otherwise excellent English Act of 1882. It does not deal with the devolution of the wife's property on intestacy. The surviving husband's rights therefore remain unaltered, and he remains exclusively entitled to all her personal estate, though, no property acquired by the wife (since the Act of 1882) vesting in the husband, he has to take out letters of administration to get possession of it.

An Act of 1884 made husband and wife competent witnesses in criminal proceedings against each other under the 1882 Act.

A further Act in 1893 repealed two clauses in that of 1882, the exact bearing of which had been a subject of controversy. It provided specifically that every contract thereafter entered into by a married woman, otherwise than as an agent, should be deemed to be a contract entered into by her with respect to and be binding upon her separate property, whether she was or was not in fact possessed of or entitled to any separate property at the time when she entered into such contract, that it should bind all separate property which she might at any time or thereafter be possessed of or entitled to, and that it should be enforceable by process of law against all property which she might thereafter, while discoverable, be possessed of or entitled to.

One of the most interesting and significant changes in the law affecting married women was that introduced by the Guardianship of Infants Act, 1886 (49 and 50 Vict. c. 27), providing that the mother of any infant may by deed or will appoint any person or persons to be guardian or guardians of her child after the death of herself and the father of such infant, and that where guardians are appointed by both parents they shall act jointly, and that the mother of any infant may by deed or will provisionally nominate some fit person or persons to act as guardian or guardians of such infant after her death jointly with the father of such infant. The Court, after her death, if it be shown to its satisfaction that the father is for any reason unfitted to be the sole guardian of his children, may confirm the appointment of such guardian

Married women's powers in appointment of guardians.

or guardians, who thereupon are authorized and empowered so to act. (See also INFANTS.)

In spite of active and ceaseless agitation on behalf of the legalization in England of marriage with a deceased wife's sister, the advocates of the abolition of the existing disability had not succeeded up to 1902 in carrying any measure for its removal through both Houses of Parliament.

In all the self-governing colonies, on the other hand, with the exception of Newfoundland, the restriction has ceased to exist. The first Act legalizing marriage with a deceased wife's sister was adopted by South Australia. The royal assent, however, was not given till the Parliament of that state had five times passed the Bill. In quick succession similar statutes followed in Victoria, Tasmania, New South Wales, Queensland, New Zealand, West Australia, Barbados, Canada, Mauritius, Natal, and Cape Colony. As regards the Channel Islands, marriages of the kind in question were made legal some years ago in Jersey, but neither in the other islands, nor in the Isle of Man, has similar progress been made.

In England the Bill to render marriage with a deceased wife's sister valid was first adopted by the House of Commons in 1850, and rejected by the House of Lords in 1851. It was subsequently brought before the legislature in 1855, 1856, 1858, 1859, 1861, 1862, 1866, 1869, 1870, 1871, 1872, 1873, 1875, 1877 and 1878 (Colonial Bills), 1879 (6th May, when in the House of Lords the prince of Wales and the duke of Edinburgh voted in favour of it), 1880, 1882, 1883, 1884, 1886, 1888, 1889, 1890, 1891, 1896, and 1898 and 1900 (Colonial Bills). In most cases it has been passed by the House of Commons and rejected in the House of Lords. In fact, few subjects have such power of exciting interest among the Peers as the Marriage with a Deceased Wife's Sister Bill. It was observed that they mustered to deal with it as if the destiny of the nation depended on its rejection. (See *Annual Register*, 1901, p. 121.) The Bill of 1896, however, which was judiciously drafted to avoid the compulsory celebration by clergymen of marriages against which they had conscientious scruples, was carried in the Lords. Both the prince of Wales and the duke of York were among the "ayes." The prime minister and eighteen bishops, including the two archbishops, voted against the Bill, the Earl of Rosebery and Lord Kimberley for it. At the third reading the Bill was carried by 142 to 104 votes. Its promoters, however, did not succeed in getting an opportunity of bringing it before the House of Commons.

From 1896 to 1901 no further direct steps were taken, but in 1898 and again in 1900 (28th May) the subject was brought forward in the House of Lords by Lord Strathcona in the form of a Bill under which marriages with a deceased wife's sister contracted in any British colony should be deemed valid for all purposes within the United Kingdom. In 1898 the Bill was carried on the second reading by 129 to 46 votes, the prince of Wales, the duke of Devonshire, and most of the Liberal Unionist peers voting in the majority, and on the third reading without a dissentient vote. The House of Commons took no action. In 1900 the Bill was supported by Lord Carrington, a former colonial governor, and Lord Kimberley, a former colonial secretary, and in spite of the opposition of the Lord Chancellor and the archbishop of York, it was carried on the second reading by 116 to 31 votes, and on the third reading again without a dissentient vote. The House of Commons, however, again took no action. An Imperial Bill reached a second reading in the House of Commons in 1901 and

again in 1902, but it was blocked by the opponents of the measure when attempts were made to get it to the committee stage (5th February and 6th June).

The Foreign Marriage Act, 1892, has consolidated the English law relating to marriages celebrated abroad, and brings it into harmony with the current tendencies of marriage law reform generally. Under it a marriage between British subjects on land abroad is as valid as a marriage duly solemnized in England (as heretofore), if celebrated in accordance with the local law or in the presence of a "marriage officer." "Marriage officers" are diplomatic or consular agents who are appointed to act as such. The old fiction of assimilation of a British embassy to British soil can no longer be relied upon to uphold a marriage at a British embassy solemnized by an ordained clergyman. An Order in Council of 28th October 1892, moreover, provides that in the case of any marriage under the Act, if it appears to the marriage officer that the woman about to be married is a British subject, and that the man is an alien, he must be satisfied that the marriage will be recognized by the law of the foreign country to which the alien belongs.

A marriage may be solemnized on board one of His Majesty's ships at a foreign station, provided a warrant of a secretary of state has authorized the commanding officer to be a marriage officer. At sea, marriages on British public or private ships seem still valid at common law, if performed by an episcopally-ordained minister. The Merchant Shipping Act, 1894 (sect. 240), provides that the master of a ship for which an official log is required shall enter in it every marriage taking place on board, with the names and ages of the parties.

Again, under the Foreign Marriage Act all marriages solemnized within the British lines by a chaplain or officer or other person officiating under the orders of the commanding officer of a British army serving abroad, are as valid in law as if they had been solemnized within the United Kingdom subject to due observance of all forms required by law.

The principle of the English law of marriage, that a marriage contracted abroad is valid if it has been solemnized according to the *lex loci*, may be now taken to apply just as much to a marriage in a heathen as in a Christian country. Whether the marriage has or has not been celebrated according to Christian laws has no bearing upon the question, provided it is a monogamous marriage—a marriage which prevents the man who enters into it from marrying any other woman while his wife continues alive.¹ In *Hyde v. Hyde and Wolmansee* Lord Penzance refused relief on the ground that Mormon marriages are polygamous, although both parties were single at the time the marriage was contracted; and in *Bethell v. Hildyard*, Stirling J. decided against the validity of the marriage on the ground that the marriage which Mr Bethell intended to contract was not a marriage in the Christian sense, but a marriage in the sense in which the term was used among the Barologs, which implies the power of taking another wife—that it was, in fact, a polygamous marriage. In *Brinkley v. The Attorney-General*, on a petition to establish the validity of a marriage between a British subject, temporarily resident in Japan, and a Japanese woman in Japan, according to the forms required by the law of the latter country, the marriage was upheld, the President of the Court observing that the phrase "Christian marriage" had been used, only for convenience' sake, to express the idea that

¹ Compare the duke of Argyll's somewhat tempestuous assertion, in the debate of 1896 on the Marriage with a Deceased Wife's Sister Bill, that marriage as understood all over the Christian world was the product of Christianity and of Christianity alone.

Marriage with a deceased wife's sister.

Private international law.

the only marriage recognized in Christian countries is marriage of the exclusive kind, which the Japanese marriage was proved to be.

II. UNITED STATES.

If we define marriage as a physical, legal, and moral union between man and woman in complete community of life for the establishment of a family,¹ it is possible to discriminate between three stages in the history of the institution—the animal or physical stage, the proprietary or legal stage, and the personal or moral stage. In the first or physical stage the relation of the sexes was unregulated, and in many cases of brief duration. In the second or legal stage greater permanence was secured in marriage by assigning the husband a property right in his wife or wives. In the last stage the proprietary relation falls more and more into the background, and the relation of husband and wife approximates that of two individuals entirely equal before the law. Although in the history of marriage these three stages have been roughly successive, the order of their entering the conscious experience of the individual is usually the reverse of their order in the development of the race; and in the solemnization of a marriage based upon affection and choice the growth of the relation begins with the moral, advances to the legal, and culminates in the physical union, each one of these deriving its meaning and its worth from the preceding. It seems probable that in the United States marriage has

advanced into this personal or moral stage farther than it has in many countries, and certain of its characteristic features as a social relation flow from this fact. Thus it is probable that the equality of property rights between husband and wife is established in America more completely than in any other civilized country. Indeed, in many states the movement has gone so far as to give the wife in matters of property and in reference to divorce greater privileges than the husband. Thus a husband is often liable for a wife's debts where a wife would not be, *mutatis mutandis*, for a husband's; and a wife may usually obtain a decree of divorce for any ground on which one may be awarded to the husband, and, in addition, for neglect to provide sustenance or support. Emphasis on the personal or moral relation of the parties in marriage tends to throw into the background the legal aspects and requirements; and in the United States, where the separation of Church and State is probably as complete as in any civilized country, it tends also to minimize, so far as the State is concerned, the religious and sacramental aspect of marriage. In distinction from these two, the purely personal aspects of the relation are brought into the foreground. Marriage tends to become a relation established by parties between themselves, and one in which the consent of the parties becomes the only constitutive element. In the theory of American law no ceremony is essential to create the marriage relation. The dictates of social expediency find expression mainly in certain prohibitions, as upon the marriage of persons under a certain limit of age, of persons within certain degrees of relationship, of persons already married, or of persons incapable for any reason of entering into marriage. Under such a theory of the law, persons marry themselves, and it might be claimed as a legitimate corollary of this theory that they should be allowed to divorce themselves. But while in theory of law parties marry themselves, and a ceremony is unnecessary, this position has never been endorsed by any considerable proportion of the community, and in fact probably $\frac{1}{10}$ and perhaps $\frac{2}{10}$ of the marriages in the United States are contracted through some ceremony. In every state, too, some legal decree is necessary in order to terminate the marriage relationship, although in all but two a complete separation of the parties continued for from one to five years is a legal ground of divorce.

The prevalence of the institution of marriage in a community is best measured by the percentage of the population of marriageable age who are married. According to the United States census, the earlier limit of marriageable age is twenty; but in the best practice elsewhere it is fifteen, and in 1890 about 330,000 persons in the United States between fifteen and twenty were married. It seems wise therefore to assign fifteen as the earlier limit of marriageable age. Of all persons in the United States over fifteen in 1890, 55.3 per cent. were reported as married; if we add those who were reported as widowed or divorced, the percentage is raised to 63. As a measure of the prevalence of marriage these figures are too low, owing to the fact that a very large number of persons who are unmarried between fifteen and thirty marry in later years. Few marriages are contracted after the age of forty-five, and such as do occur are less important socially than those contracted earlier and when the likelihood of parentage is greater. Of the total population in the United States over the age of forty-five in 1890, 93 per cent. were or had been married. This proportion in the United States is greater than in any of the countries in Western Europe. In European countries generally the proportion of elderly spinsters is greater than the proportion of elderly bachelors, but in the United States the reverse is true. This difference is due mainly to the

¹ It is doubtless true, as anthropologists have pointed out, that in the history of the race "marriage is rooted in the family rather than the family in marriage" (Westermarck, *History of Human Marriage*, p. 22); but in that conscious experience of the individual with which law and ethics are especially concerned, this relationship is reversed, and the family originates in marriage.

unequal distribution of the sexes. Among the adults in western Europe there is an excess of females, in the United States generally an excess of males; and therefore the likelihood of a man's marrying is somewhat greater in western Europe, and that of a woman's marrying is somewhat greater in the United States. The same difference appears within the limits of the United States itself, for in the states of the Atlantic coast women outnumber the men, while in the rest of the country the reverse is true. Consequently, states on the Atlantic coast from Maine to the Carolinas have the largest percentage of spinsters among the women between fifty-five and sixty-five, and the states west of the Mississippi have the smallest percentage. On the contrary, the percentage of bachelors among the men between fifty-five and sixty-five is largest in the Rocky Mountain states, in some of which it is nearly or quite one-third, and smallest in the southern states east of the Mississippi.

Regarding the age of marriage in the United States we have little direct evidence. In Massachusetts the average age at which men marry for the first time was in 1897 rather over twenty-seven, and the average age at which women marry for the first time was $24\frac{1}{2}$ years; but in other parts of the country, and especially in the southern states, marriage occurs much earlier. For in Massachusetts in 1890 the percentage of girls between fifteen and twenty who were married was less than 4, and below that of any other state, while in the states of the far south the percentage ranged from 15 to 20. In Massachusetts, of the men between twenty and twenty-five, about 15 per cent. were returned in 1890 as married, while in the states of the far south the ratio was more than twice as great. Nor is this due to the many coloured people in the southern states, for, although they marry earlier than the whites, the whites also marry earlier than the whites in the north. While the percentage of married persons in the United States is probably greater than in most countries of western Europe, the tendency in this as in most other social respects is for the conditions on the two sides of the Atlantic to approximate. So far as fragmentary returns from certain states enable one to judge, the percentage of persons over fifteen in the United States who are married tends to decrease, and the age at which marriage occurs tends to rise. In Massachusetts the percentage of married persons among those over fifteen decreased by 4 between 1875 and 1895, and the average age at which marriage occurred increased nearly a year for each sex between 1871 and 1897. One reason for the decreasing marriage-rate characteristic of most industrial countries calls for more attention than has thus far been given it by social students, and that is a tendency to establish a separation of the sexes whereby a decided excess of women is found in industrial or manufacturing towns, offset more or less completely by an excess of men in the rural districts. For example, in the United States there are more women than men in the 1522 cities of over 2500 inhabitants taken as a whole, and in nearly all states east of the Mississippi the excess is marked. In the rural districts, on the contrary, there are over a million and a half more males than females. Under such conditions a certain number of women in cities and of men in the country will be debarred from marriage.

One inference derivable from the figures of the census of 1890 is that in the large cities girls do not marry so early as they do in the rural districts of the same states. For example, in Chicago among the young women between fifteen and twenty years of age about 6 per cent. are married, but in the rest of the state the percentage of the married at those ages is about $7\frac{1}{2}$. This early marriage of the young women in the rural districts is not paralleled by a similarly early marriage of young men, for in two-

thirds of the largest cities in the country the proportion of married men between twenty and twenty-five years of age was smaller than in the state at large. The early marriage of women in the rural districts is probably closely connected with the excess of men, which makes women more in demand. The same influence may be traced in the differences between the several states. As one passes westwards, the percentage of males in the total population increases; and in a general way it is also true that as one passes west the percentage of women between fifteen and twenty who are married increases; while the percentage of men between twenty and twenty-five who are married diminishes—that is, the sex in the minority marries in larger numbers and at earlier ages than the sex which is in the majority. (W. F. W.)

Mars. See ASTRONOMY, vol. xxv.

Marsala, a seaport town of the province of Trapani, Sicily, Italy, on the west coast, 19 miles by rail south of Trapani. It is the centre of the production of "Marsala" wine, and has also iron works, cooperages, and macaroni factories. There is an export trade (declining) in wine (£227,000 to £533,000), wine lees, cheese, &c., to the average value of £465,000 annually; and an import trade to the annual value of £20,000 to £50,000. In 1899 the port was cleared by 1072 vessels of 230,400 tons. In 1898 the construction of a mole was begun to protect the harbour against west and south-west winds. Population (1881), 19,732; (1900), about 37,000.

Marseilles, capital of the department of the Bouches-du-Rhône, France, 516 miles from Paris by rail. It is the headquarters of the 15th army corps, of a rear-admiral in command of the local naval defences, and of an episcopal see.

Population.—The census of 1900 has shown that Marseilles, by distancing Lyons to the extent of 27,000 inhabitants, has become the second town of France. Of its 498,610 inhabitants, 98,835 are foreigners, comprising 91,536 Italians and 469 British subjects, including the Maltese and British seamen in the port.

Trade and Commerce.—Since the opening of the Suez Canal, Marseilles has been the French gate of the Far East, in addition to being the western emporium for the Levant trade. But, as large ships now discharge cargo at all small ports, Marseilles is no longer the storehouse for the western Mediterranean. It has also suffered from the competition of Genoa since the opening of the St Gothard railway route to Switzerland and Germany. But its local industries—its oil mills, soap manufactories, sugar refineries, and others of minor importance—provide commercial activity to its port. Marseilles has suffered from the monopolies of the Dock Company and the Paris-Lyons-Mediterranean Railway Company. The Dock Company's warehouses, built at a time when goods were stored for prolonged periods, are no longer needed, and the company's rates for working cargo are far in excess of the rates charged by the Chamber of Commerce on the free quays. This obstruction to the full development of trade is being met (1) by the gradual increase of the quay space under the control of the Chamber of Commerce; (2) by the gradual completion of the seventh dock, the Bassin de la Pinède; and (3) by the proposal to make the Old Port accessible to steamers drawing 24 feet. The Chamber of Commerce proposes to deepen it to 24 feet 7 inches, to widen the quays, and connect them with the Joliette dock by rail. The monopoly of the "P.L.M." Railway Company is to be met by the construction of a ship canal from Marseilles to the Rhône at Arles. The competition will bring about a reduction in the exorbitant railway rates. The Chamber of Deputies voted 91,400,000 francs for the canal in January 1902. A large anchorage basin is to be constructed to the west of the Bassin de

la Pinède by utilizing the small stream of La Madrague. The proposed canal will start from this Bassin de la Madrague, and, communicating by a passage 100 metres long with the Bassin de la Pinède, will pass under the Estaque mountain range by a tunnel to Port de Bouc, on the famous Étang de Berre; thence to Arles on the Rhône. The canal which connects the Étang de Berre with the sea, near the mouths of the Rhône, will be enlarged, and the Étang de Berre will become a great port of refuge for the protection of naval and mercantile shipping in time of war. The utility of the Marseilles-Arles canal will be ultimately enormously enhanced by the construction of a canal parallel to the Rhône from Arles to Lyons. The Chamber has also voted 123,000,000 francs for the construction of a canal to connect the Rhône with the Loire, which will place Marseilles in connexion with the north of France. The canal to Arles was first planned by Vauban, and the terrain surveyed by skilled engineers in the early part of the 19th century, and mapped out as now proposed by Guérard in 1879. Owing to the unhealthy and swampy nature of the Rhône delta, Marseilles was not built at the mouth of that river, but on a sheltered bay facing west, a little to the east of the river mouth, separated from it by a high range of hills and a dangerous bit of sea round Cape Couronne. Hence the urgent need for this canal.

Education.—Marseilles has a lycée (grammar school) for boys and one for girls, a school of medicine, a law college, a higher school of commerce (with a colonial section and a mercantile marine section attached to it), and, since 1899, a lower-grade commercial school for the training of boys from 12 to 15.

Public Health.—Marseilles has for many years been free from the epidemics which in former days gave it an unenviable reputation. The extensive drainage works, on the *tout à l'égout* system, were completed in 1898, and the sewage is carried miles away to sea beyond Cape Croisette. The old harbour frequented by yachts is no longer polluted by drainage. Every house is fitted with sanitary appliances on the flush system, the adoption of which was rendered feasible by the completion of the Durance canal, which brings the water of that river across a range of granite mountains to Marseilles and its once arid suburbs. Marseilles has a Pasteur Anti-Rabic Vaccination Institute, and three large hospitals. But owing to the rapid increase of the population, hospital accommodation is still lamentably deficient.

Public Buildings.—The Roman Catholic cathedral, built in Byzantine style, and overlooking the Joliette dock, was opened for public worship in 1893. All Saints', an English church, has been built in the Rue de Belloi, close to the Cours Pierre Puget, the heart of the fashionable quarter of the town. The town has extended principally on the south-eastern slope of the Notre-Dame-de-la-Garde hill, between the southern end of the Rue Paradis and the Prado avenues, which is more protected than most other quarters from the mistral that blows down the Rhône valley, and where in summer the temperature is always a little lower than in the centre of the town.

Industries.—Marseilles produces sugar, soap, seed, oil, oil-cake, tiles and bricks, candles, flour, bran, macaroni and other pastes, semolina, and liqueurs. It exported during 1901, 4584 tons of almonds and nuts, 17,987 tons of bran, 10,618 tons of bricks and tiles, 4916 tons of candles, 1390 tons of dried and preserved fruits, 22,930 tons of grain and flour, 28,828 tons of semolina, 14,989 tons of crushed ochre, 7246 tons of castor oil, 5672 tons of cocoanut oil, 4149 tons of cotton-seed oil, 10,664 tons of olive oil, 54,364 tons of oil-cake, 24,146 tons of potatoes, 19,509 tons of soap, 52,360 tons of refined sugar, 12,748 tons of cotton tissues, 8,019,412 gallons of wine, 4436

tons of raw wool, &c. There were imported during 1901, 1,200,338 head of cattle and sheep, 1,110,262 tons of coal, 21,900 tons of coffee, 14,292 tons of raw cotton, 469,236 tons of grain, 16,602 tons of hides, 162 tons of indigo, 77,467 tons of maize, 37,375 tons of cotton-seed oil, 15,112 tons of palm oil, 26,866 tons of castor-oil seed, 80,468 tons of copra, 65,817 tons of ginglyly, 126,976 tons of ground-nuts, 10,575 tons of linseed, 8825 tons of palm-nuts, 11,352 tons of rice, 4966 tons of raw silk, 5703 tons of floss silk, 31,969 tons of sugar, 1617 tons of sulphate of copper, 1278 tons of tea, 11,447,744 gallons of wine, 29,319 tons of wool, &c. Marseilles has also a branch of the Forges et Chantiers de la Méditerranée, where boilers and engines are turned out for the navy and merchant ships, and a shipbuilding yard, the Chantiers de Provence, where large liners are built.

Communications.—Marseilles is the terminus of three lines of railway, all forming part of the Paris-Lyons-Mediterranean system, viz., a main line to Paris, *via* Lyons; a main line to Nice and Italy; a branch line to Aix, Grenoble, and the Alps. There are five stations, three of which are practically confined to the service of the port. There are also four suburban stations. The station in the Old Port belongs to an English, the others to the "P.L.M." company. Thirty-six shipping companies make the city a port of call in their regular service, besides those whose headquarters are at Marseilles. The Messageries Maritimes has a fleet of 52 vessels, of a total tonnage of 96,517 net. Their mail boats leave for the Far East every fortnight, and twice monthly for Zanzibar, Madagascar, Réunion, and Mauritius; and there is a weekly service to the Levant, and also to London. Other well-known companies are the Fraissinet Company, the Société Générale des Transports Maritimes, and the Navigation Mixte Company. Of British companies touching at Marseilles the most important are the Peninsular and Oriental, the Orient-Pacific, the British India, the Anchor Line, and the Bibby Line.

Shipping.—Marseilles is the chief port of France, having accommodation for over 2500 vessels at one time. During 1901 the number of ships entered and cleared amounted to 16,478, whereof 11,558 were French, 1355 British, 1296 Italian, 801 Spanish, and 327 Austro-Hungarian. The total tonnage of ships entering and clearing during 1901 was 13,040,814 net, of which French shipping claimed only 6,573,373 tons, and foreign shipping 6,467,441 tons. British shipping amounted to 3,264,698 tons, more than a quarter of the total tonnage of the port, and half the tonnage of all foreign nations combined. The volume of merchandise loaded and discharged during 1902 amounted to 5,763,553 tons, whereof 1,085,701 went to the credit of British shipping. The water space available for shipping purposes at Marseilles comprises some 297 acres, inclusive of the various canals of communication between the different harbours. The length of quay space for purposes of loading and discharging cargo is 42,988 feet in all at present. Of this some 3000 feet belong to the Old Port. The Joliette dock has 5260 feet, the Lazaret and Arenc docks 7483 feet, the Gare Maritime dock 7000 feet, the National dock has 12,316 feet of quay space in length. For the storage of merchandise there are 3,400,000 square feet of space available. Of this total 261,383 feet are around the old harbour and the Canal des Douanes. The Joliette dock has 339,246 square feet; the "Stationnement" dock, annexed to it, another 25,000 feet; the Lazaret and Arenc docks have together 754,283 square feet; the Gare Maritime dock, 586,671 feet; the National dock, the most commodious of all, has 1,000,000 square feet; the graving dock, 50,000 square feet; and the outer harbour has 341,730. The Chamber of Commerce owns and works appliances for manipulating cargo on the Gare Maritime and National docks, and the old harbour. (M. C. G.)

Marsh, Othniel Charles (1831-1899), American palæontologist, was born in Lockport, New York, on 29th October 1831. He graduated at Yale College in 1860, and having from boyhood been deeply interested in collecting birds, insects, minerals, and fossils, spent five years after his college graduation in studying (in the Sheffield Scientific School, New Haven, and in Germany)

geology, palæontology, and mineralogy. Becoming professor of vertebrate palæontology at Yale in 1866, he continued his researches, particularly in the fossil deposits of the western states, greatly aided by a private fortune from his uncle, George Peabody, whom he also induced to establish the Peabody Museum of Natural History (especially devoted to zoology, geology, and mineralogy) in the college. In May 1871 he discovered the first pterodactyle remains found in America, and in subsequent years he brought to light other important objects, most of which he described in monographs of periodical articles. His discovery in 1872 of remains of the toothed bird *Hesperornis* and of *Ichthyornis*, a cretaceous bird with biconcave vertebræ, and of various fossil mammalia in Wyoming, aroused active discussion, and in some cases led to real or alleged proof of the existence of hitherto unknown ancestors of extant mammalia, or to the establishment of extinct transitional links between existent birds and reptiles. Still more earnest discussion followed, in 1874 and in later years, on his discoveries of remains of peculiar fossil horses in America. On becoming vice-president of the American Association for the Advancement of Science in 1875 he gave an address on the "Introduction and Succession of Vertebrate Life in America," summarizing his conclusions, to that date, in the branch to which his life was devoted. He repeatedly organized, and often accompanied, scientific exploring expeditions in the Rocky Mountains, not infrequently at personal risk; and their results, as set forth in his writings, tended in an important degree to support the doctrines of natural selection and evolution. Although he failed to complete several works of importance, he published many papers in addition to those mentioned, and found time—besides that necessarily given to the accumulation and care of the most extensive collection of fossils in the world—to write *Odontornithes: A Monograph on the Extinct Toothed Birds of North America* (1880), and *Dinocerata: A Monograph on an Extinct Order of Gigantic Mammals* (1886). He was long in charge of the division of vertebrate palæontology in the United States Geological Survey, and received many scientific honours, medals, and degrees, American and foreign. He died in New Haven on 18th March 1899. (C. F. R.)

Marshall, a city of Missouri, U.S.A., capital of Saline county, on the high prairie, near the Salt Fork of Lamine river, a little west of the centre of the state, at an altitude of 570 feet. Its site is undulating and its plan regular. It is at the intersection of the Missouri Pacific and the Chicago and Alton railways. Marshall is the seat of Missouri River College, a Presbyterian institution, founded in 1889, which in 1899 had 14 instructors and 222 students, 95 of whom were women. Population (1890), 4297; (1900), 5086, of whom 129 were foreign-born and 724 were negroes.

Marshall, a city of Texas, U.S.A., capital of Harrison county, in the north-eastern part of the state, on the Texas and Pacific and the Texas Southern railways, at an altitude of 366 feet. It is in an agricultural and lumber region, and contains works of the Texas and Pacific railway, saw and planing mills, and other manufactories. It is the seat of Wiley University, a Methodist Episcopal institution, opened in 1873, which had in 1899 a faculty of 9 and an attendance of 54 students. Population (1890), 7207; (1900), 7855, of whom 258 were foreign-born and 3769 were negroes.

Marshall Islands, an island group in the North Pacific, belonging to Germany since 1886. The group consists of a number of atolls ranged in two almost parallel lines, which run from north-west to south-east,

between 4° and 15° N. The north-east group, with fifteen islands, is called Ratak, the other, numbering eighteen, Ralik. These atolls are of coralline formation and of irregular shape. They rise but little above high-water mark. The highest elevation occurs on the island of Likieb, but is only 33 feet. The lagoon is scarcely more than 150 feet deep, and is accessible through numerous breaks in the reef. On the outward side the shore sinks rapidly to a great depth. The surface of the atolls is covered with sand, except in a few places where it has been turned into soil through the admixture of decayed vegetation. The reef in scarcely any instance exceeds 600 feet in width. The climate is moist and hot, the mean temperature being 80-50° Fahr. Easterly winds prevail all the year round. There is no difference between the seasons, which, though the islands belong to the northern hemisphere, have the highest temperature in January and the lowest in July. Vegetation, on the whole, is very poor. There are many cocoanut palms, bread-fruit trees (*Artocarpus incisa*), and pandanus, of which the natives eat the seeds. From the bark of another plant they manufacture mats. Animals are scarce. Pigs, cats, dogs, rats are imported. There are a few pigeons and aquatic birds, few butterflies and beetles. Crustacea and fish abound on the reefs. The natives are of dark brown colour, though lighter shades occur. They belong to the Micronesian races. Their hair is not woolly, but straight and long. They are expert navigators, and construct curious charts of little sticks. Their canoes carry sails, and are made of the trunk of the bread-fruit tree. The people are divided into four classes, of which only two are allowed to own land. They practise tattooing, and consequently wear few clothes. The islands lie entirely within the German sphere of interest, and the boundaries were agreed upon between Great Britain and Germany on the 10th April 1889. Their area is estimated at 150 square miles, with 15,000 inhabitants, who are apparently beginning to increase again, though the contrary was long believed. In 1899 there were 79 Europeans (50 German). The administrator of the islands is at present the Governor of German New Guinea, but a number of officials reside on the islands. There is no military force, the natives being of peaceful disposition. The chief island and seat of government is Jaluit. The most populous island is Majeru, with 2600 inhabitants. The natives are pagans. A Roman Catholic mission has been established, and the American Mission Board maintains coloured teachers on many of the islands. There is communication with Sydney by private steamer, and a steamer sails between Jaluit and Ponape to catch the French boats for Singapore. The islands belong to the Postal Union. The chief products for export are copra, tortoise-shell, mother-of-pearl, sharks' fins, and trepang. For consumption Nature offers the bread-fruit, various kinds of bananas, taro, yams, the bulbous roots of the *Tacca pinnatifida*, and the seeds of a pandanus. Cereals are entirely unknown. The natives plant cocoa-palms in yearly increasing numbers. Cattle do not thrive on these islands, and even fowl are scarce. The natives are clever boat-builders, and sell their canoes not only on their own but to neighbouring islands. They have made such progress in their art that they have even built seaworthy little schooners of from 30 to 40 tons. The only other things they make are a few shell ornaments. In 1898-99 the value of the imports was 465,700 marks; exports, 900,000 marks, mainly copra. (J. VON F.)

Marshall, John (1818-1891), British surgeon and physiologist, was born at Ely, 11th September 1818, his father being a lawyer of that city. He entered University College, London, in 1838 (M.R.C.S. 1844, F.R.C.S. 1849). In 1847 he was appointed assistant-surgeon at

the hospital, and in 1866 surgeon and professor of surgery. He was professor of anatomy at the Royal Academy from 1873 till his death. In 1882 he was president of the College of Surgeons, also Bradshaw lecturer (on "Nerve-stretching for the relief or cure of pain"), Hunterian orator in 1885, and Morton lecturer in 1889. In 1867 he published his well-known text-book *The Outlines of Physiology* in two volumes. He died 1st January 1891. "Marshall's fame," wrote Sir W. Mac Cormac in his volume on the *Centenary of the College of Surgeons* (1900), "rests on the great ability with which he taught anatomy in relation to art, on the introduction into modern surgery of the galvano-cautery, and on the operation for the excision of varicose veins. He was one of the first to show that cholera might be spread by means of drinking water, and issued a report on the outbreak of cholera in Broad Street, St James's, 1854. He also invented the system of circular wards for hospitals, and to him are largely owing the details of the modern medical student's education."

Marshalltown, a city of Iowa, U.S.A., capital of Marshall county, on the Iowa river, near the centre of the state, at an altitude of 895 feet. It is at the intersection of the Chicago Great Western, the Chicago and North-Western, and the Iowa Central railways. It is in a rich agricultural region, and has grain elevators and varied manufactures. Population (1890), 8914; (1900), 11,544, of whom 1590 were foreign-born and 148 were negroes.

Marshfield, a city of Wood county, Wisconsin, U.S.A., in the central part of the state, on three railway lines. It is in a timber region, and has extensive manufactures of furniture, barrels, and other wooden goods. Population (1890), 3450; (1900), 5240, of whom 1161 were foreign-born.

Marsivan, or MERZIFÜN, a town in the Amasia sanjak of the Sivas vilâyet of Asia Minor, situated at the foot of the Tavshan Dag. It is a centre of American missionary and educational enterprise, and is the seat of Anatolia College, a theological seminary, and schools. In November 1895 many Armenians were massacred. Population, 30,000, one-third Armenian.

Marston, Philip Bourke (1850-1887), English poet, was born in London on 13th August 1850. His father, JOHN WESTLAND MARSTON (1819-1890), of Lincolnshire origin, the friend of Dickens, Macready, and Charles Kean, was the author of a series of metrical dramas which held the stage in succession to the ambitious efforts of Tobin, Talfourd, Bulwer, and Sheridan Knowles. His chief plays were *The Patrician's Daughter* (1841), *Strathmore* (1849), *A Hard Struggle* (1858), and *Donna Diana* (1863). He was looked up to as the upholder of the outworn tradition of the acted poetic drama, but his plays showed little vitality, and Marston's reviews for the *Athenæum*, including one of Swinburne's *Atalanta in Calydon*, and his dramatic criticisms embodied in *Our Recent Actors* (2 vols. 1888) will probably claim a more enduring reputation. The son, PHILIP BOURKE, was born in a literary atmosphere. His sponsors were Philip James Bailey and Dinah Mulock (Mrs Craik). At his father's house near Chalk Farm he met authors and actors of his father's generation, and subsequently the Rossettis, Swinburne, Arthur O'Shaughnessy, and Irving. From his earliest years his striking literary precocity was overshadowed by misfortunes which make his career one of the most pathetic in literary history. In his fourth year, in part owing to an accident, his sight began to decay, and he gradually became almost totally blind. His mother, who had devoted herself to him, died in 1870.

His promised bride, Mary Nesbit, died in 1871; his closest friend, Oliver Madox Brown, in 1874; his sister Cicely, his amanuensis and second self, in 1878; in 1879 his remaining sister, Eleanor, who was followed to the grave after a brief interval by her husband, the poet O'Shaughnessy (1846-1881), and her two children. In 1882 the death of his chief poetic ally and inspirer, Rossetti, was followed closely by the tragedy of another kindred spirit, the sympathetic pessimist, James Thomson, who was carried dying from his blind friend's rooms, whither he had sought refuge from his latest miseries early in June of the same year. It is said that Marston came to dread making new friendships, for fear of evil coming to the recipients of his affection. In the face of such calamities it is not surprising that Marston's verse, in which a plaintive minor key was always apparent, became more and more persistently sorrowful and melancholy. The idyls of flower-life, such as the early and very beautiful "The Rose and the Wind," were succeeded by longing dreams of sleep and the repose of death. These qualities and gradations of feeling, reflecting the poet's successive ideals of action and quiescence, are traceable through his three published collections, *Songtide* (1871), *All in All* (1875), and *Wind Voices* (1883). The first and third, containing his best work, went out of print, but Marston's verse was collected in 1892 by Mrs Louise Chandler Moulton, a most loyal and devoted friend, and herself a poet. Marston read little else but poetry, and of poetic values, especially of the intenser order, his judgment could not be surpassed in sensitiveness. As a creative artist he rarely approached supreme excellence, though in delicate facility and melodious prettiness and, it must be added, diffuseness, he was a prince among minor poets. He was saturated with Rossetti and Swinburne, and his imitative power was most remarkable. His tendency was ever to transpose into a minor key, and there was an absence of the "masculine bass" in all that he wrote. In his later years he endeavoured to make a little money by writing short stories, and succeeded in finding a market for them in *Home Chimes* and other American magazines, through the agency of Mrs Chandler Moulton. His popularity in America far exceeded that in his own country. With an outlook more and more sombre owing to the loss of friends, the narrowing of resources, and the development of insomnia, Marston gradually lost the buoyancy which he had retained through grievous misfortunes. His health showed definite signs of collapse from 1883; in January 1887 he lost his voice, and suffered intensely from the failure to make himself understood. He died on 13th February 1887 at his lodgings, 191 Euston Road, and, like his friend "B. V." (Thomson), he was by express desire hurried in unconsecrated ground in Highgate cemetery. He was commemorated in Dr Gordon Hake's "Blind Boy," and in a fine sonnet by Swinburne, commencing "The days of a man are three score years and ten." There is an intimate sketch of the blind poet by a friend, Mr Coulson Kernahan, in *Sorrow and Song* (1894), p. 127.

(T. SE.)

Martel de Janville [SIBYLLE-GABRIELLE-MARIE-ANTOINETTE DE RIQUETI DE MIRABEAU], COMTESSE DE (best known as "GYP"), French writer, was born in 1850 at Koëtsal in the Morbihan. Her father, who was grandson of Mirabeau *Tonneau*, and great-nephew of the orator, served in the Papal Zouaves, and died during the campaign of 1860. Her mother, the comtesse de Mirabeau, in addition to some graver compositions, contributed to the *Figaro* and the *Vie Parisienne*, under various pseudonyms, papers in the manner successfully developed by her daughter. Under the pseudonym of "Gyp" Madame de

Martel, who was married in 1869, sent to the *Vie Parisienne*, and later to the *Revue des Deux Mondes*, a large number of social sketches and dialogues, afterwards reprinted in volumes. Her later work includes stories of a more formal sort, essentially differing but little from the shorter studies. The following list includes some of the best known of Madame de Martel's publications, nearly seventy in number: *Petit Bob* (1882); *Autour du mariage* (1883); *Ce que femme veut* (1883); *Le monde à côté* (1884); *Sans voiles* (1885); *Autour du divorce* (1886); *Dans le train* (1886); *Mademoiselle Loulou* (1888); *Bob au Salon* (1888-89); *L'éducation d'un prince* (1890); *Passionette* (1891); *Ohé! La grande vie* (1891); *Une élection à Tigresur-Mer* (1890), an account of "Gyp's" experiences in support of a Boulangist candidate; *Mariage civil* (1892); *Ces bons docteurs* (1892); *Du haut en bas* (1893); *Mariage de chiffon* (1894); *Leurs dames* (1895); *Le cœur d'Ariane* (1895); *Le bonheur de Ginette* (1896); *Totote* (1897); *Lune de miel* (1898); *Israel* (1898); *L'entrevue* (1899); *Le pays des champs* (1900); *Trop de chic* (1900); *Le Friquet* (1901). From the first "Gyp" writing of a society to which she belonged, displayed all the qualities which have given her a distinct, if not pre-eminent, position among writers of her class. Those qualities included an intense faculty of observation, much skill in innuendo, a mordant wit combined with some breadth of humour, and a singular power of animating ordinary dialogue without destroying the appearance of reality. Her Parisian types of the spoiled child, of the precocious schoolgirl, of the young bride, and of various masculine figures in the gay world, have become almost classical, and may probably survive as faithful pictures of luxurious manners in the 19th century. Some later productions, inspired by a violent anti-Semitic and Nationalist bias, deserve little consideration. An earlier attempt to dramatize *Autour du mariage* was a failure, not owing to the audacities which it shares with most of its author's works, but from lack of cohesion and incident. "Gyp's" successes are indeed all achieved without a trace of dramatic faculty. In 1901 Madame de Martel furnished a sensational incident in the Nationalist campaign during the municipal elections in Paris. She was said to have been the victim of a kidnapping outrage or piece of horseplay provoked by her political attitude, but though a most circumstantial account of the outrages committed on her and of her adventurous escape was published, the affair was never clearly explained or verified.

Martello Tower.—The name is a corruption of Mortella, and the large adoption of towers so styled for purposes of coast defence is due to incidents in the war of the French Revolution. In September 1793, Commodore Linzee, in command of the line-of-battle ships *Alcide*, *Courageux*, *Ardent*, with the frigates *Lowestoffe* and *Nemesis*, was ordered by Lord Hood, then in possession of Toulon, to support the Corsican insurgents under General Paoli, who had sought British assistance. Linzee determined to attack Fornielli, and in the first place to take a tower on Cape Mortella which commanded the only secure anchorage in the Gulf of San Fiorenzo. This tower, according to James, was named "after its inventor"; but the real derivation appears to be the name of a wild myrtle which grew thickly on the spot. The tower, which mounted one 24-pounder and two 18-pounders on its top, was bombarded for a short time by the *Lowestoffe* and *Nemesis* frigates, was then deserted by its little garrison, and occupied by a landing party of 30 men under Lieutenants Gibbs and Annesley. The attack on Fornielli failed, and the tower was abandoned, and afterwards retaken by the French from the Corsicans. So far it had done nothing to justify its subsequent reputation. Early in 1794, how-

ever, a fresh attempt was decided upon by Lord Hood and Major-General Dundas, to support the Corsican insurgents. On the 7th February, 1400 troops were landed in a bay to the west of Cape Mortella, and the tower was attacked by land and sea on the following day. The *Fortitude* and *Juno* kept up a bombardment for 2½ hours and then hauled off, the former being on fire, and having 62 men killed and wounded. The fire from the batteries on shore produced no impression, until a hot shot set fire to the "bass junk with which to the depth of 5 feet the immensely thick parapet" of the tower "was lined." The garrison of 33 men under Ensign Le Tellier then surrendered. The armament was found to consist only of two 18-pounders and one 6-pounder, and the strong resistance offered by these three guns seems to have led to the conclusion that towers of this description were specially formidable. There appears to be nothing in the circumstances to justify this conclusion. As a result of the invasion scares which it was Napoleon's policy to promote and maintain, Martello towers were built in large numbers, and at heavy expense, along the shores of England, especially on the southern and eastern coasts, which in certain parts are lined with these species of fortification placed at short intervals. Their principal characteristics are solid masonry containing vaulted rooms in the interior for the garrison, and providing a platform at the top for two or three guns, firing over a low masonry parapet. Access, as in the far older Irish towers, is provided by a wooden ladder, communicating with a door about 20 feet above the ground. In some cases a deep ditch is provided around the base of the tower; in others, the ditch is absent. It is interesting to note that the towers of Linz begun in 1833 by the Archduke Maximilian were similar in conception, as also was the Malakoff tower built by subscription among the merchants of Sebastopol, which was the one completed example of permanent fortification existing on the south side when the Allies commenced the siege. The Malakoff tower proved a positive disadvantage to the defence by adding greatly to the losses of the defenders of the extemporized redoubt which was built round it. While the Martello tower owes its reputation as a work of defence and its widespread adoption in Great Britain to the misconception arising out of a single incident of war, the round masonry structure entered by a single door raised high above the base is far older than the events of 1794. Such structures are to be found in many lands, and are amongst the earliest examples of masonry fortification. (G. S. C.)

Martensen, Hans Larsen (1808-1884), Danish bishop and theologian, was born at Flensburg on 19th August 1808. He was ordained in the Danish Church, and ultimately became professor of theology at Copenhagen, as well as court preacher. His life was uneventful, but his contributions to theological literature were neither few nor unimportant. Among them were treatises on Christian ethics and dogmatics, on moral philosophy, on baptism, and a sketch of the life of the celebrated mystic Jacob Böhme, who exercised so marked an influence on the mind of the great English theologian of the 18th century, William Law. Martensen was a distinguished preacher, and his works were translated into various languages. His treatises on Christian ethics and dogmatics, in particular, have been widely read in Great Britain. He was made bishop of Zealand in 1854, and died at Copenhagen on 4th February 1884. He was a man of original mind, departed in many ways from the strict standards of Lutheran orthodoxy, and showed a disposition towards mysticism in many of his works. The "official" eulogy he pronounced upon Bishop Mynster, on

the death of this dignitary in 1854, brought down upon his head the scathing invectives which the philosopher Kierkegaard poured forth on the text, "A witness of the truth."
(J. J. L*.)

Martial Law.—"Martial law" is an unfortunate term, and in a sense a misnomer. It describes a suspension of ordinary law, rendered necessary by circumstances of war or rebellion. The confusion arose from the fact that the Marshal's Court administered military law before the introduction of articles of war, which were in their turn merged in the Army Act. But martial law is not a law in the proper sense of the term. It is the exercise of the will of the military commander, who takes upon himself the responsibility of suspending ordinary law in order to ensure the safety of the State. It is declared, by a proclamation issued by the executive, that ordinary law is inadequate to cope with the actual circumstances, and provides exceptional means of arrest and punishment of persons who resist the Government, or who aid and abet the enemy. But such a proclamation, whilst it is invariably issued in order to give publicity to the suspension of ordinary law, does not invest the step with the force of law. In short, martial law arises out of the will of the commander, and he acts from necessity, and in order to deal more summarily with civilians. It is simply military authority exercised in accordance with the laws and usages of war, and is limited by military necessity. Yet in reality it is part of common law which justifies acts done by necessity for the defence of the Commonwealth when there is war. Halleck in his work on International Law (vol. i. p. 544), says, "Martial law originates either in the prerogative of the Crown, as in Great Britain, or from the exigency of the occasion, as in other states: it is one of the rights of sovereignty, and is essential to the existence of a state, as is the right to declare or to carry on war."

This opinion, however, must be read, as regards the British Empire, with the passage in the Petition of Right which is reproduced in the preamble of each annual Army Act, and asserts the illegality of martial law in time of peace in the following terms:—"No man shall be forejudged or subjected in time of peace to any kind of punishment within this realm by martial law." Therefore, whilst martial law is declared illegal in time of peace, it is indirectly declared lawful in time of war and intestinal commotion when the courts are closed, or when there is no time for their cumbrous action. Clode, in *Military Forces of the Crown*, argues that the words of the Petition of Right and of the Military Act since the reign of Anne are plain in this respect "that . . . the Crown possesses the right of issuing commissions in war and rebellion." But he rightly adds that the military commander may permit the usual courts to continue their jurisdiction upon such subjects as he thinks proper. Legislative enactments have also sanctioned this special jurisdiction at various times, notably in 1798, 1799, 1801, and in 1803. These enactments lay down that exceptional powers may be exercised "whether the ordinary courts shall or shall not be open." As an invariable rule an Act of Indemnity has been passed on the withdrawal of martial law, but that has been done only to protect any person in charge of the execution of martial law who has exceeded his powers in good faith, honestly believing his action was necessary for the safety of the country.

There has been much discussion as to whether, in districts where martial law has not been proclaimed, a person can be sent for trial from such district into a district where martial law was in operation. It is argued that if the ordinary courts were open and at work in the non-proclaimed district recourse should be had to them.

The Privy Council in 1902 (*re Marais*) refused leave to appeal where the Supreme Court of Cape Colony had declined to issue a writ of Habeas Corpus in these circumstances. Mr Justice Blackburn in his charge in *Queen v. Eyre* says, "I have come to the conclusion that, looking at what martial law was, the bringing of a person into the proclaimed district to be tried might, in a proper case, be justified." The learned judge admits that there should be a power of summary trial, observing all the substantial of justice, in order to stamp out an insurrection by speedy trial.

Whilst martial law is the will of the commanders, and is only limited by the customs of war and the discretion of those who administer it, still, as far as practicable, the procedure of military law is followed, and a military court is held on the same lines as a court-martial. Charges are simply framed without technicalities. The prisoner is present, the evidence of prosecution and prisoner is taken on oath, the proceedings are recorded, and the sentence of the court must be confirmed according to the rules of the Army Act. Sentences of death and penal servitude must be referred to headquarters for confirmation. In the South African war (1899-1902) these limits of procedure were observed, and when possible will always be.

Entering more into detail, the term martial law has been employed in several senses:—(1) As applied to the military forces of the Crown, apart from the military law under the old Mutiny Acts, and the present annual Army Acts. (2) As applied to the enemy. (3) As applied to rebels. (4) As applied to civilian subjects who are not in rebellion, but in a district where the ordinary course of civil life cannot be maintained owing to war or rebellion.

Different applications of martial law.

1. In regard to the military forces of the Crown, the superseding of justice as administered under the Army Act could only occur in a time of great need; *e.g.*, mutiny of five or six regiments in the field, with no time to take the opinion of any executive authority. The officer in command would then be bound to take measures for the purpose of suppressing such mutiny, even to putting soldiers to death if necessary. It would be a case where necessity forced immediate action.

2. Martial law as applied to the enemy or the population of the enemy's country is, in the words of the duke of Wellington, "the will of the general of the army, though it must be administered in accordance with the customs of war."

3, 4. But it is as affecting the subjects of the Crown in rebellion that the subject of martial law really obtains its chief importance; and it is in this sense that the term is generally used; *i.e.*, the suspension of ordinary law and the temporary government of the country, or parts of it, or all of it, by military tribunals. It has often been laid down that martial law in this sense is unknown to the law of England. Mr Dicey, for instance, restricts martial law to only another expression for "the common right of the Crown and its servants to repel force by force, in the case of invasion, insurrection, or riot, or generally of any violent resistance." But more than this is understood by the term martial law.

When the proposition was laid down that martial law in this sense is unknown to the law of England, it is to be remembered that fortunately in England there never had been a state at all similar to that prevailing in Cape Colony in 1900-1902, and it may perhaps be questioned whether the statement would have been made with such certainty if similar events had been present to the writers' minds.

In the charge delivered by Mr Justice Blackburn in the Jamaica case, which has already been cited, the law as

affecting the general question of martial law is well set out.

"By the laws of this country," said Mr Justice Blackburn, "beginning at Magna Charta and getting more and more established, down to the time of the Revolution, when it was finally and completely established, the general rule was that a subject was not to be tried or punished except by due course of law; all crimes are to be determined by juries subject to the guidance of the judge; that is the general rule, and is established law. But from the earliest times there was this also which was the law, and is the law still, that when there was a foreign invasion or an insurrection, it was the duty of every good subject, in obedience to the officers and magistrates, to resist the rebels, . . . in such a case as that of insurrection prevailing so far that the courts of law cannot sit, there must really be anarchy unless there is some power to keep the people in order, . . . before that principle the Crown claimed the prerogative to exercise summary proceedings by martial law . . . in time of war when this disturbance was going on, over others than the army. And further than that, the Crown made this further claim against the insurgents, that whilst it existed, pending the insurrection and for a short time afterwards, the Crown had . . . the power to proclaim martial law in the sense of using summary proceedings, to punish the insurgents and to check and stop the spread of the rebellion by summary proceedings against the insurgents, so as . . . to stamp out the rebellion. Now no doubt the extent to which the Crown had power to do that has never been yet decided. Our law has been declared from time to time and has always been a practical science, that is, the judges have decided so much as was necessary for the particular case, and that has become part of the law. But it never has come to be decided what this precise power is."

So far as the United Kingdom is concerned, the need has never arisen. It has always been found possible to employ the ordinary courts directly the rebels have been defeated in the field and have been made prisoners or surrendered. "Fortunately in England only three occasions have arisen since the Revolution when the authority of the civil power was for a time, and then only partially, suspended," 1715, 1745 and 1780. Clode, *Military Forces*, vol. ii. p. 163, says: "Upon the threat of invasion followed by rebellion in 1715, the first action of the Government was to issue a proclamation authorizing all officers, civil and military, by force of arms (if necessary) to suppress the rebellion." This, therefore, would only seem to fall within the limited sense in which Mr Dicey understands martial law to be legal, "the right of the Crown and its servants to repel force by force." There was no attempt to bring persons before courts-martial who ought to be tried by the common law, and all the extraordinary acts of the Crown were sanctioned by Parliament. After the rebellion had been suppressed two statutes were passed, one for indemnity and the other for pardon. Before the revolution of 1745 similar action was adopted, a proclamation charging civil magistrates to do their utmost to prevent and suppress all riots, and Acts of Parliament suspending Habeas Corpus, providing for speedy trials; and of indemnity. In the Gordon Riots of 1780 a very similar course was pursued, and nothing was done which would not fall within Mr Dicey's limitation. No prisoners were tried by martial law.

In Ireland the ordinary law was suspended in 1798-1801 and in 1803. In 1798 an Order in Council was issued to all general officers commanding H.M. forces to punish all persons acting in, aiding, or in any way assisting the rebellion, according to *martial law*, either by death or otherwise, as to them should seem expedient for the suppression and punishment of all rebels; but the order was communicated to the Irish Houses of Parliament, who expressed their approval by addresses to the viceroy. It was during the operation of this order that Wolfe Tone's case arose. Tone, a subject of the king, was captured on board a French man-of-war, and condemned to death by a court-martial. Curran, his counsel, applied to the King's Bench at Dublin for a

Habeas Corpus, on the grounds that only when war was raging could courts-martial be endured, not while the Court of King's Bench sat. The court granted his application; but no ultimate decision was ever given, as Tone died before it could be arrived at.

In 1799 application was made to Parliament for express sanction to martial law. The preamble of the Act declared that "The Rebellion still continues . . . and stopped the ordinary course of justice and of the common law; and that many persons . . . who had been taken by H.M. forces . . . had availed themselves of such partial restoration of the ordinary course of the common law to evade the punishment of their crimes, whereby it had become necessary for Parliament to interfere." The Act declared that martial law should prevail and be put in force whether the ordinary courts were or were not open, &c. And nothing in the Act could be held to take away, abridge, or eliminate the acknowledged prerogative of war, for the public safety to resort to the exercise of martial law against open enemies or traitors, &c.

After the suppression of the rebellion an Act of Indemnity was passed in 1801.

In 1803 a similar Act was passed by the Parliament of the United Kingdom as it was after the Act of Union. In introducing it Mr Pitt stated, "The Bill is not one to enable the Government in Ireland to declare martial law in districts where insurrection exists, for that is a power which His Majesty already possesses—the object will be to enable the Lord Lieutenant, when any persons shall be taken in rebellion, to order them to be tried immediately by a court-martial."

During the 19th century martial law was proclaimed by the British Government in the following places:—

- | | |
|---------------------------|------------------------------|
| 1. Barbados, 1805-16. | 7. Cape of Good Hope, 1834— |
| 2. Demerara, 1823. | 1849-51. |
| 3. Jamaica, 1831-32—1865. | 8. St Vincent, 1863. |
| 4. Canada, 1837-38. | 9. Jamaica, 1865. |
| 5. Ceylon, 1817 and 1848. | 10. South Africa, 1899-1901. |
| 6. Cephalonia, 1848. | |

The proclamation was always based on the grounds of necessity, and where any local body of a representative character existed it would seem that its assent was given, and an Act of Indemnity obtained after the suppression of the rebellion. (JNO. S.)

Martin, Bon Louis Henri (1810-1883), French historian, was born on the 20th of February 1810 at St Quentin (Aisne), where his father was a judge. Trained as a notary, he followed this profession for a while, but having by his twentieth year achieved success with a historical romance, *Wolfthurm* (1830), applied himself seriously to historical research. Becoming associated with Paul Lacroix ("le Bibliophile Jacob"), he planned with him a history of France, which was to consist of excerpts from the chief chroniclers and historians, with original matter filling up the gaps in the continuity. The first volume, which appeared in 1833, encouraged the author to make the work his own, and his *Histoire de France*, in fifteen volumes (1833-36), was the result. This *magnum opus*, rewritten and further elaborated (1837-54), gained for the author in 1856 the first prize of the Academy, and in 1869 the grand biennial prize of 20,000 francs. A popular abridgment in seven volumes was published in 1867. This, together with the continuation, *Histoire de France moderne depuis 1789 jusqu'à nos jours*, gives a complete history of France, and superseded Sismondi's *Histoire des Français*. Henri Martin's reputation is that of a conscientious, impartial, and scrupulously accurate writer, although he can hardly be ranked among the world's great historians. He sat in the Assembly as deputy for Aisne in 1871, and was elected life senator for

the same province in 1878, but he did not leave any real mark as a politician. He died in Paris on 14th December 1883.

Among minor works which proceeded from his pen may be mentioned. *De la France, de son génie et de ses destinées* (1847), *La Russie et l'Europe* (1866), *Les Napoléon et les frontières de la France* (1874).

Martin, Helena Saville (1817–1898), English actress, best known under her maiden name as HELEN FAUCIT, was born in London in 1817. Her stage *début* was made in January 1836 at Covent Garden Theatre, as Julia in *The Hunchback*. Her success in this was so definitely confirmed by her subsequent acting of such parts as Juliet, Lady Teazle, Beatrice, Imogen, and Hermione, that within eighteen months from her first appearance she was engaged by Macready as leading lady at Covent Garden. There, besides appearing in several Shakespearian characters, she “created” the heroine’s part in Lytton’s *Duchess de la Vallière* (1836), *Lady of Lyons* (1838), *Richelieu* (1839), *The Sea Captain* (1839), *Money* (1840), and Browning’s *Strafford* (1837). After a visit to Paris and a short season at the Haymarket Theatre, she joined the Drury Lane company under Macready early in 1842. At Drury Lane she played for the first time the parts of Lady Macbeth, Constance in *King John*, Desdemona and Imogen, and took part in the first production of Westland Marston’s *Patrician’s Daughter* (1842) and Browning’s *Blot in the Scutcheon* (1843). The next two years were occupied with tours in England, Scotland, and Ireland, her acting meeting everywhere with unstinted praise, and a visit to Paris (in the winter of 1844–45), when she acted with Macready in several Shakespearian plays. After six more years passed almost entirely in acting in various parts of the United Kingdom, she was married in August 1851 to Mr (afterwards Sir) Theodore Martin. She did not relinquish her profession after marriage, but appeared on the stage at frequent intervals during the next twenty years, until her definite retirement in 1871. After that she would only consent to act in public for charitable purposes. In 1881 there appeared in *Blackwood’s Magazine* the first of her *Letters on Some of Shakespeare’s Heroines*, which were ultimately published in book form (under the title of *On Some of Shakespeare’s Female Characters*) in 1885. The latter years of her life were spent in a seclusion which increased as her health declined, but was marked by numerous marks of honour and admiration from the highest personages and the greatest intellects in the land. She died at her home in Wales on 31st October 1898. (R. F. S.)

Martin, Sir Theodore (1816—), author and translator, the son of a solicitor, was born in Edinburgh on 16th September 1816, and educated at the Royal High School and the University, from which he subsequently received the honorary degree of LL.D. He practised for some time as a solicitor in Edinburgh, but in 1846 went to London, where he became senior partner in the firm of Martin and Leslie, parliamentary agents. He early contributed to *Fraser’s Magazine* and *Tait’s Magazine*, under the signature of “Bon Gaultier,” and in 1856, in conjunction with Professor Aytoun, he published the *Book of Ballads* under the above pseudonym. This work at once obtained popular favour. In 1858 he published a volume of translations of the *Poems and Ballads of Goethe*, and this was followed by a rendering of the Danish poet Henrik Hertz’s noble lyric drama, *King René’s Daughter*. The principal character in this drama, Iolanthe, was sustained by Miss Helen Faucit, who in 1851 became the author’s wife. Martin’s translations of Ohlenschläger’s dramas, *Correggio* (1854), and

Aladdin, or the Wonderful Lamp (1857), widened the fame of the great Danish poet in England, and materially assisted in familiarizing readers with his dramatic masterpieces. In 1860 appeared Martin’s metrical translation of the *Odes of Horace*; and in 1870 he wrote a volume on Horace for the series of “Ancient Classics for English Readers.” In 1882 his Horatian labours were concluded by a translation of the poet’s whole works, with a life and notes, in two volumes. A poetical translation of *Catullus* was published in 1861, followed by a privately printed volume of *Poems, Original and Translated*, in 1863. Then came translations of the *Vita Nuova* of Dante, and the first part of Goethe’s *Faust*. A metrical translation of the second part of *Faust* appeared in 1866. Martin wrote a memoir of his friend Aytoun in 1867, and while engaged upon this work he was requested by Queen Victoria to undertake the *Life of His Royal Highness the Prince Consort*. The first volume of this well-known work was published in 1874. In 1878 Martin’s translation of Heine’s *Poems and Ballads* appeared. Two years later the *Life of the Prince Consort* was brought to a successful conclusion by the publication of the fifth volume. A knighthood was then conferred upon Martin, whose association with the Queen added to the influence which his literary position had already achieved. In the following November he was elected Lord Rector of the University of St Andrews. Martin’s *Life of Lord Lyndhurst*, based on papers furnished by the family, was published in 1883. In 1889 appeared *The Song of the Bell, and other Translations from Schiller, Goethe, Uhland, and Others*; in 1894 *Madonna Pia, a Tragedy, and three other Dramas*, and in 1900 he published a biography of his accomplished wife. All Sir Theodore Martin’s translations are distinguished for their singular fidelity to the originals, but perhaps the finest and most spirited are those from Goethe and Horace.

Martin, Sir William Fanshawe (1801–1895), British admiral, son of Admiral of the Fleet Sir Thomas Byam Martin, Comptroller of the Navy, and grandson, on the mother’s side, of Captain Robert Fanshawe, who commanded the *Namur* under Rodney on 12th April 1782, was born on 5th December 1801. Entering the navy at the age of twelve, his father’s interest secured his rapid promotion: he was made a lieutenant on 15th December 1820; on 8th February 1823 he was promoted to be commander of the *Fly* sloop, his good service in which in support of the interests of British merchants at Callao during one of the continually recurring civil wars gave the Admiralty a legitimate excuse—if one had been needed—for promoting him to be captain on 5th June 1824. He afterwards served in the Mediterranean and on the home station, but without any opportunities of distinction, though known in the navy as a good officer. In 1849–52 he was commodore commanding the Channel squadron, and at once gave evidence of a remarkable aptitude for command—of being a man who knew what he wanted and how to get it done. He was made rear-admiral in May 1853, and for the next four years was superintendent of Portsmouth dockyard. He was made vice-admiral in February 1858, and after a year as a Lord of the Admiralty, was appointed commander-in-chief in the Mediterranean. The discipline of the navy was just then at a very low ebb. It was an evil tradition, sprung from the wholesale shipment of gaol-birds during the old war, that the men were to be treated as brute beasts; and though the practice was better than the theory, it was still very bad. At this time, too, the ships had been largely filled up with “bounty men”—men who had been bought into the service with a £10 note, without being sailors or having

even an elementary notion of cleanliness or obedience. Out of this very unpromising material Martin formed the fleet which was at the time the ideal of excellence, and may be said to have laid the foundations of the magnificent organization of a later day. It is solely in this connexion that his name stands out among the naval officers of the century, for he had no war service, and, beyond the Italian disturbance of 1860-61, no opportunity for showing any diplomatic ability. But his memory will deservedly live as that of the reformer of discipline and the originator of a comprehensive system of steam manœuvres. He became an admiral in November 1863, and on 4th December succeeded to the baronetcy which had been originally conferred on his grandfather. His last appointment was the command at Plymouth, 1866-69, and in 1870 he was put on the retired list. In 1873 the G.C.B. was conferred on him, and in 1878 he was made rear-admiral of the United Kingdom. He died at Upton Grey, near Winchfield, on 24th March 1895. He was twice married, and left, besides daughters, one son, who succeeded to the baronetcy.

(J. K. L.)

Martineau, James (1805-1900), English philosopher and divine, was born at Norwich, 21st April 1805, the seventh child of Thomas Martineau and Elizabeth Rankin, the sixth, his senior by almost three years, being his sister Harriet (*Ency. Brit.* vol. xv. pp. 583-584). He was descended from Gaston Martineau, a Huguenot surgeon and refugee, who married in 1693 Marie Pierre, and settled soon afterwards in Norwich. His son and grandson—respectively the great-grandfather and grandfather of James Martineau—were surgeons in the same city, while his father was a manufacturer and merchant. Affinity of faith made the French Huguenot an English Presbyterian, and the Martineaus could not fail to share the discipline, the culture, and the intellectual changes of the society within which they lived. James was educated at Norwich Grammar School under Edward Valpy, as elegant a classic and as fastidious a scholar as his better-known brother Richard. But the boy proving too sensitive for the rough-and-tumble life of a public day school, was sent to Bristol to the private academy of Dr Lant Carpenter, a conscientious master, an earnest philanthropist, and a laborious divine, well known for his part in the Socinian controversies of the day, under whom he studied for two years. On leaving there he was apprenticed to a civil engineer at Derby, where he acquired “a store of exclusively scientific conceptions,”¹ but where he also experienced the hunger of mind which forced him to look to religion for satisfaction. Hence came his “conversion,” and the sense of vocation for the ministry which impelled him in 1822 to enter Manchester College, then lodged at York. Here he “woke up to the interest of moral and metaphysical speculations.” Of his teachers, one, the Rev. Charles Wellbeloved, was, Martineau said, “a master of the true Lardner [*Ency. Brit.* vol. xiv. p. 313] type, candid and catholic, simple and thorough, humanly fond indeed of the counsels of peace, but piously serving every bidding of sacred truth.” “He never justified a prejudice; he never misdirected our admiration; he never hurt an innocent feeling or overbore a serious judgment; and he set up within us a standard of Christian scholarship to which it must ever exalt us to aspire.”² The other, the Rev. John Kenrick, he described as a man so learned as to be placed by the late Dean Stanley “in the same line with Blomfield and Thirlwall,”³ and as “so far above the level of either vanity

or dogmatism, that cynicism itself could not think of them in his presence.”⁴

On leaving the college in 1827 Martineau returned to Bristol to teach in the school of Lant Carpenter; but in the following year he was ordained for a Unitarian church in Dublin whose senior minister was a relative of his own. But his career there was in 1832 suddenly cut short by difficulties growing out of the “Regium donum,” which had on the death of the senior minister fallen to him. He conceived it as “a religious monopoly,” to which “the nation at large contributes” while “Presbyterians alone receive,” and which placed him in “a relation to the State” so “seriously objectionable” as to be “impossible to hold.”⁵ The invidious distinction it drew between Presbyterians on the one hand, and Catholics, Friends, freethinking Christians, unbelievers, and Jews on the other, who were compelled to support a ministry they “conscientiously disapproved,” offended his always delicate conscience; while possibly the intellectual and ecclesiastical atmosphere of the city proved uncongenial to his liberal magnanimity. From Dublin he was called to Liverpool, and there for a quarter of a century he exercised extraordinary influence as a preacher, and achieved a high reputation as a writer in religious philosophy. In 1840 he was appointed professor of mental and moral philosophy and political economy in Manchester New College, the seminary in which he had himself been educated, and which had now removed from York to the city after which it was named. This position he held for forty-five years. In 1853 the college removed to London, and four years later he followed it thither. In 1858 he was called to occupy the pulpit of Little Portland Street Chapel in London, which he did at first for two years in conjunction with the Rev. J. J. Tayler, who was also his colleague in the college, and then for twelve years alone. In 1866 the chair of the philosophy of mind and logic in University College, London, fell vacant, and Martineau became a candidate. But potent opposition was offered to the appointment of a minister of religion, and the chair went to George Croom Robertson—then an untried man—between whom and Martineau a cordial friendship came to exist. From 1869 to 1880 he was one of the most active, as he was possibly the most distinguished philosophical, member of the famous Metaphysical Society, which, though it might contribute little to thought or knowledge, yet accomplished the immense indirect good of making eminent men, who held diverse views in religion and philosophy, personally acquainted. In 1885 he retired, full of years and honours, from the principalship of the college he had so long served and adorned. It ought to be recorded, were it only as significant of the happier spirit of the time, that Martineau, who was in his youth denied the benefit of a university education, yet in his age found famous universities eager to confer upon him their highest distinctions. He [was made LL.D. of Harvard in 1872, S.T.D. of Leyden in 1874, D.D. of Edinburgh in 1884, D.C.L. of Oxford in 1888, and D.Litt. of Dublin in 1891. He died in London on 11th January 1900.

The life of Martineau was so essentially the life of the thinker, and was so typical of the century in which he lived and the society within which he moved, that he can be better understood through his spoken mind than through his outward history. He was a man happy in his ancestry: he inherited the dignity, the reserve, the keen and vivid intellect, and the picturesque imagination of the French Huguenot, though they came to him chastened

⁵ Martineau's “Letter to the Dissenting Congregation of Eustace Street” (Dublin).

and purified by generations of Puritan discipline exercised under the gravest ecclesiastical disabilities, and of culture maintained in the face of exclusion from academic privileges. He had the sweet and patient temper which knew how to live, unrepining and unsoared, in the midst of the most watchful persecution, public and private; and it is wonderful how rarely he used his splendid rhetoric for the purposes of invective against the spirit and policy from which he must have suffered deeply, while, it may be added, he never hid an innuendo under a metaphor or a trope. He had the advantage of being educated by men who had no inducement to seek knowledge, save such as came from love of truth; and though he knew how much he had lost by never having lived within a learned society full of the great traditions of ancient and modern scholarship, yet he would have been the first to claim that he who has had to follow in feebleness, and amid storm and stress, the truth that drew him on, has received an education that may do more than the discipline of any college to dignify the conscience, to quicken the intellect, and to enrich the imagination. For these and similar reasons he was lifted above the temptations which beset the mere scholar or the thinker bound to maintain his formulated beliefs. He was fundamentally too much a man of strong convictions to be correctly described as open-minded, for if nature ever determined any man's faith, it was his; the root of his whole intellectual life, which was too deep to be disturbed by any superficial change in his philosophy, being the feeling for God. He has, indeed, described in graphic terms the greatest of the more superficial changes he underwent; how he had "carried into logical and ethical problems the maxims and postulates of physical knowledge," and had moved within the narrow lines drawn by the philosophical instructions of the classroom "interpreting human phenomena by the analogy of external nature"; how he served in willing captivity "the 'empirical' and 'necessarian' mode of thought," even though "shocked" by the dogmatism and acrid humours "of certain distinguished representatives";¹ and how in a period of "second education" at Berlin, "mainly under the admirable guidance of Professor Trendelenburg," he experienced "a new intellectual birth" which "was essentially the gift of fresh conceptions, the unsealing of hidden openings of self-consciousness, with unmeasured corridors and sacred halls behind; and, once gained, was more or less available throughout the history of philosophy, and lifted the darkness from the pages of Kant and even Hegel."² But though this momentous change of view illuminated his old beliefs

and helped him to re-interpret and re-articulate them, yet it made him no more of a theist than he had been before. And as his theism was, so was his religion and his philosophy. Certainly it was true of him, in a far higher degree than of John Henry Newman, that the being of God and himself were to his mind two absolutely self-luminous truths—though both his God and his self were almost infinitely remote from Newman's. And as these truths were self-evident, so the religion he deduced from them was sufficient, not only for his own moral and intellectual nature, but also for man as he conceived him, for history as he knew it, and for society as he saw it.

JAMES MARTINEAU.

(From a photograph by Elliott and Fry, London.)

so he became a positive religious teacher by virtue of the very ideas that made the words of the Hebrew prophets so potent and sublime. But he did more than interpret to his age the significance of man's ultimate theistic beliefs, he gave them vitality by reading them through the consciousness of Jesus Christ. His religion was what he conceived the personal religion of Jesus to have been; and He was to him more a person to be imitated than an authority to be obeyed, rather an ideal to be revered than a being to be worshipped.

Martineau's mental qualities fitted him to fulfil these high interpretative functions. He had the imagination that invested with personal being and ethical qualities the most abstruse notions. To him space became a mode of divine activity, alive with the presence and illumined by the vision of God: time was an arena where the divine hand guided and the divine will reigned. And though he did not believe in the Incarnation, yet he held deity to be in a sense manifest in Humanity; its saints and heroes became, in spite of innumerable frailties, after a sort divine; man underwent an apotheosis, and all life was touched with the dignity and the grace which it owed to its source. The 19th century had no more reverent thinker than Martineau; the awe of the Eternal was the very atmosphere that he breathed, and he looked at man with the compassion of one whose thoughts were full of God.

To his function as a preacher we owe some of his most characteristic and stimulating works, especially the discourses by

We may, alternatively, describe Martineau's religion as his applied philosophy, or his philosophy as his explicated religion, and both as the expression of his singularly fine ethical and reverent nature. But to understand these in their mutual and explanatory relations, it will be necessary to exhibit the conditions under which his thought grew into consistency and system. His main function made him in his early life a preacher even more emphatically than a teacher. In all he said and all he thought he had the preacher's end in view. He was, indeed, no mere orator or speaker to multitudes. He addressed a comparatively small and select circle, a congregation of thoughtful and devout men, who cultivated reverence and loved religion all the more that their own beliefs were limited to the simplest and sublimest truths. He felt the majesty of these truths to be the greater that they so represented to him not only the most fundamental of human beliefs, but also all that man could be reasonably expected to believe, though to believe with his whole reason. Hence the beliefs he preached were never to him mere speculative ideas, but rather the ultimate realities of being and thought, the final truths as to the character and ways of God interpreted into a law for the government of conscience and the regulation of life. And

which it may be said he won his way to wide and influential recognition—*Endeavours after the Christian Life*, 1st series, 1843; 2nd series, 1847; *Hours of Thought*, 1st series, 1876; 2nd series, 1879; the various hymn-books he issued at Dublin in 1831, at Liverpool in 1840, in London in 1873; and the *Home Prayers* in 1891. But besides the vocation he had freely selected and assiduously laboured to fulfil, two more external influences helped to shape Martineau's mind and define his problem and his work; the awakening of English thought to the problems which underlie both philosophy and religion, and the new and higher opportunities offered for their discussion in the periodical press. The questions which lived in the earlier and more formative period of his life concerned mainly the idea of the Church, the historical interpretation of the documents which described the persons who had created the Christian religion, especially the person and work of its Founder; but those most alive in his later and maturer time chiefly related to the philosophy of religion and ethics. In one respect Martineau was singularly happy; he just escaped the active and, on the whole, belittling period of the old Socinian controversy. When his ministry began its fires were slowly dying down, though the embers still glowed. We feel its presence in his earliest notable work, *The Rationale of Religious Enquiry*, 1836; and may there see the rigour with which it applied audacious logic to narrow premisses, the tenacity with which it clung to a limited literal supernaturalism which it had no philosophy to justify, and so could not believe without historical and verbal authority. This traditional conservatism survived in the statement, which, while it caused vehement discussion when the book appeared, was yet not so much characteristic of the man as of the school in which he had been trained, that "in no intelligible sense can any one who denies the supernatural origin of the religion of Christ be termed a Christian," which term, he explained, was used not as "a name of praise," but simply as "a designation of belief."¹ He censured the German rationalists "for having preferred, by convulsive efforts of interpretation, to compress the memoirs of Christ and His apostles into the dimensions of ordinary life, rather than admit the operation of miracle on the one hand, or proclaim their abandonment of Christianity on the other."² The echoes of the dying controversy are thus distinct and not very distant in this book, though it also offers in its larger outlook, in the author's evident uneasiness under the burden of inherited beliefs, and his inability to reconcile them with his new standpoint and accepted principles, a curious forecast of his later development, while in its positive premisses it presents a still more instructive contrast to the conclusions of his later dialectic. Nor did the sound of the ancient controversy ever cease to be audible to him. In 1839 he sprang to the defence of Unitarian doctrine, which had been assailed by certain Liverpool clergymen, of whom Fielding Ould was the most active and Hugh M'Neile the most famous. As his share in the controversy, Martineau published five discourses, in which he discussed "the Bible as the great autobiography of human nature from its infancy to its perfection," "the Deity of Christ," "Vicarious Redemption," "Evil," and "Christianity without Priest and without Ritual."³ He remained to the end a keen and vigilant apologist of the school in which he had been nursed. But the questions proper to the new day came swiftly upon his quick and susceptible mind—enlarged, deepened, and developed it. Within his own fold new light was breaking. To Channing, whom Martineau had called "the inspirer of his youth," Theodore Parker had succeeded, introducing more radical ideas as to religion and a more drastic criticism of sacred history. Blanco White, "the rationalist & Kempis," who had dared to appear as "a religious sceptic in God's presence," had found a biographer and interpreter in Martineau's friend and colleague, John Hamilton Thom. Within the English Church men with whom he had both personal and religious sympathy rose—Whately, of whom he said, "We know no living writer who has proved so little and disproved so much";⁴ and Arnold, "a man who could be a hero without romance";⁵ Maurice, whose character, marked by "religious realism," sought in the past "the witness to eternal truths, the manifestation by time-samples of infinite realities and unchanging relations";⁶ and Kingsley, "a great teacher," though one "certain to go astray the moment he becomes didactic."⁷ Beside these may be placed men like Pusey, and Newman, whose mind Martineau said was "critical, not prophetic, since without immediateness of religious vision," and whose faith is "an escape from an alternative scepticism, which receives the *veto* not of his reason but of his will,"⁸ as men for whose teachings and methods he had a potent and

stimulating antipathy. The philosophic principles and religious deductions of Dean Mansel he disliked as much as those of Newman, but he respected his arguments more. Apart from the Churches, men like Carlyle and Matthew Arnold—with whom he had much in common—influenced him; while Herbert Spencer in England and Comte in France afforded the antithesis needful to the dialectical development of his own views. He came to know German philosophy and criticism, especially the criticism of Baur and the Tübingen school, which affected profoundly his construction of Christian history. And these were strengthened by French influences, notably those of Rénan and the Strasburg theologians. The rise of evolution, and the new scientific way of looking at nature and her creative methods, compelled him to rethink and reformulate his theistic principles and conclusions, especially as to the forms under which the relation of God to the world and His action within it could be conceived. Under the impulses which came from these various sides Martineau's mind lived and moved, and as they successively rose he promptly, by appreciation of criticism, responded to the dialectical issues which they raised.

In the discussion of these questions the periodical press supplied him with the opportunity of taking an effective part. At first his literary activity was limited to sectional publications, and he addressed his public, now as editor and now as leading contributor, in *The Monthly Repository*, *The Christian Reformer*, *The Prospective*, *The Westminster*, and *The National Review*. Later, especially when scientific speculation had made the theistic problem urgent, he was a frequent contributor to the literary monthlies. And when in 1890 he began to gather together the miscellaneous essays and papers written during a period of sixty years, he expressed the hope that, though "they could lay no claim to logical consistency," they might yet show "beneath the varying complexion of their thought some intelligible moral continuity," "leading in the end to a view of life more coherent and less defective than was presented at the beginning."⁹ And though it is a proud as well as a modest hope, no one could call it unjustified. For his essays are fine examples of permanent literature appearing in an ephemeral medium, and represent work which has solid worth for later thought as well as for the speculation of their own time. There is hardly a name or a movement in the religious history of the century which he did not touch and illuminate. It was in this form that he criticized the "atheistic mesmerism" to which his sister Harriet had committed herself, and she never forgave his criticism. But his course was always singularly independent, and, though one of the most affectionate and most sensitive of men, yet it was his fortune to be so fastidious in thought and so conscientious in judgment as often to give offence or create alarm in those he deeply respected or tenderly loved.

The theological and philosophical discussions which thus appeared he later described as "the tentatives which gradually prepared the way for the more systematic expositions of the *Types of Ethical Theory* and *The Study of Religion*, and, in some measure, of *The Seat of Authority in Religion*."¹⁰ These books expressed his mature thought, and may be said to contain in what he conceived as a final form the speculative achievements of his life. They appeared respectively in 1885, 1888, and 1890, and were without doubt remarkable feats to be performed by a man who had passed his eightieth year. Their literary and speculative qualities are indeed exceptionally brilliant; they are splendid in diction, elaborate in argument, cogent yet reverent, keen while fearless in criticism. But they have also most obvious defects: they are unquestionably the books of an old man who had thought much as well as spoken and written often on the themes he discusses, yet who had finally put his material together in haste at a time when his mind had lost, if not its dialectic vigour, yet its freshness and its sense of proportion; and who had been so accustomed to amplify the single stages of his argument that he had forgotten how much they needed to be reduced to scale and to be built into an organic whole. In the first of these books his nomenclature is unfortunate; his division of ethical theories into the "unpsychological," "idiopsychological," and the "hetero-psychological," is incapable of historical justification; his exposition of single ethical systems is, though always interesting and suggestive, often arbitrary and inadequate, being governed by dialectical exigencies rather than historical order and perspective. In the second of the above books his idea of religion is somewhat of an anachronism; as he himself confessed, he "used the word in the sense which it invariably bore half a century ago" as denoting "belief in an ever-living God, a divine mind and will ruling the universe and holding moral relations with mankind." As thus used, it was a term which governed the problems of speculative theism rather than those connected with the historical origin,

the evolution and the organization of religion. And these are the questions which are now to the front. These criticisms mean that his most elaborate discussions came forty years too late, for they were concerned with problems which agitated the middle rather than the end of the 19th century. But if we pass from this criticism of form to the actual contents of the two books, we are bound to confess that they constitute a wonderfully cogent and persuasive theistic argument. That argument may be described as a criticism of man and his world used as a basis for the construction of a reasoned idea of nature and being. Man and nature, thought and being, fitted each other. What was implicit in nature had become explicit in man; the problem of the individual was one with the problem of universal experience. The interpretation of man was therefore the interpretation of his universe. Emphasis was made to fall on the reason, the conscience, and the will of the finite personality; and just as these were found to be native in him they were held to be immanent in the cause of his universe. What lived in time belonged to eternity; the microcosm was the epitome of the macrocosm; the reason which reigned in man interpreted the law that was revealed in conscience and the power which governed human destiny, while the freedom which man realized was the direct negation both of necessity and of the operation of any fortuitous cause in the cosmos.

It was not possible, however, that the theistic idea could be discussed in relation to nature only. It was necessary that it should be applied to history and to the forces and personalities active within it. And of these the greatest was of course the Person that had created the Christian religion. What did Jesus signify? What authority belonged to Him and to the books that contain His history and interpret His person? This was the problem which Martineau attempted to deal with in *The Seat of Authority in Religion*. The workmanship of the book is very unequal: historical and literary criticism had never been Martineau's strong point; for years he had deserted it, and when as an old man he returned to it he found its problems changed from what they had been in his earlier manhood. Nor did he allow himself time to digest the new material; indeed, he had lost the inclination to occupy the later points of view or follow the exacter critical methods. In its speculative parts the book is quite equal to those that had gone before, but in its literary and historical parts it is in an even higher degree than they the book of an old man in whom a long-practised logic had become a rooted habit. It does not represent a mind that had throughout its history lived and worked in the delicate and judicial investigations he here tried to conduct.

Martineau's theory of the religious society or Church was that of a dreamer rather than of a statesman or practical politician. He stood equally remote from the old Voluntary principle, that "the State had nothing to do with religion," and from the sacerdotal position that the clergy stood in an apostolic succession, and either constituted the Church or were the persons into whose hands its guidance had been committed. He hated two things intensely, a sacrosanct priesthood and an enforced uniformity. He may be said to have believed in the sanity and sanctity of the State rather than of the Church. Statesmen he could trust as he would not trust ecclesiastics. And so he would have rejoiced in any scheme that would have repealed uniformity, taken the Church out of the hands of a clerical order, and allowed the co-ordination of sects or churches under the State. Not that he would have allowed the State to touch doctrine, to determine polity or discipline; but he would have had it to recognize historical achievement, religious character and capacity, and endow out of its ample resources those societies which had vindicated their right to be regarded as making for religion. His ideal may have been academic, but it was the dream of a mind that thought nobly both of religion and of the State.

(A. M. F.)

Martinique, a French West Indian colony, one of the Antilles, 50 miles from St Vincent, 33 miles south of Dominica and 22 miles north of St Lucia. It has an area of about 390 square miles, and was considered, previously to the disaster of 1902 (see below), one of the most fertile parts of the West Indies; it was regarded almost as a pet colony by the French. Apart from other circumstances, Martinique is historically interesting as being the birth-place and early home of the Empress Josephine, and also the residence for some years of Françoise d'Aubigné, who married Scarron, and was afterwards celebrated as Madame de Maintenon. The island has had more than an ordinary share of tropical visitations. In 1767, 1600 persons perished in a terrible hurricane, whereby M. de la Pagerie, the father of the empress, was practically ruined; on

11th January 1839 the island experienced another severe storm; and in 1891, on 18th August, a hurricane devastated town and country, with the loss of 600 lives; and within recent years an epidemic of small-pox and several large fires have added to its misfortune. The greatest disaster of all, however, was that caused by the eruption of Mont Pelée in May 1902, by which the entire town of St Pierre and some 30,000 persons were destroyed in an incredibly short space of time. An account of this disaster is given below. Martinique is administered by a governor, assisted by a privy council, and controlled by an elective general council of 36 members. According to the state of things before May 1902 there was a court of appeal at Fort de France, and an assize court was held at St Pierre; there are two tribunals of first instance, and nine justices of the peace. The local budget for 1900 balanced at £229,190, the expenditure of France being £101,230. At Fort de France there is a law school; at St Pierre there was a *lycée* for boys and one for girls, and in the island there are primary schools with 11,500 pupils. Between 1893 and 1902 the bishop resided at St Pierre. The island is divided into 2 arrondissements—Fort de France and St Pierre—9 cantons, and 32 communes, regulated by the French law of 1884.

In 1888 the population was estimated at 175,863; in 1894 it was 187,692; and in 1902, 203,781. The number of Indian labourers had fallen from 13,000 in 1883 to 4700 in 1898; the women numbered 67,000; in the whole population blacks and half-breeds predominate. The towns, with their populations in the latter year, were Fort de France (17,274), with a harbour, said to be the finest in the Antilles, defended by three forts; St Pierre (25,792), the commercial town of the island (see below); Laurentin (10,854), Pilote River (7092), François (10,310), Robert (8056). About 180 square miles, or rather less than half the island, are under cultivation. The most important product is the sugar-cane. In 1875 the yield of sugar amounted to 50,000 tons; but the output afterwards decreased, as in all the Antilles, and in 1898 the quantity was between 37,000 and 38,000 tons. There were in 1901 in all 564 sugar works, of which 88 employed steam power. Sugar growing and refining in 1901 contributed about 85 per cent. of the exports, and even after the disasters of May 1902 it was estimated that 80 per cent. of the plantations and factories remained intact. About 38,000 acres are devoted to cereal crops. The yield of cocoa has since 1887 amounted annually to about 500 tons; but that of coffee fell to about 5½ tons. The cocoa plantations in the north of the island were overwhelmed by the eruption of 1902, but the coffee plantations were mostly uninjured. Tobacco and cotton are no longer grown, but indigo, mahogany, cinnamon, plums, and cherries figure among the products of the island. An agricultural laboratory was instituted at St Pierre in 1884. The cultivation of caoutchouc is being encouraged. The difficulty of transport is a serious hindrance to the cutting of the forests. The island contains about 50,000 head of live-stock, of which 20,000 are cattle, 20,000 pigs, and the remainder sheep, horses, and mules. The industries, besides the preparation of sugar, comprise the manufacture of arrack and rum (about 2½ millions of gallons), and of tiles and earthenware. The trade in 1882 amounted to £2,360,000; in 1898 to £7,868,540, the imports from France being of the value of £476,000, and the exports to France £752,000, the combined value being £1,228,000, the lowest during the century. After France, the United States carries on the most active trade with Martinique. In 1901 the total imports amounted to £1,078,940, and the total exports to £953,100. In 1898 the shipping entered and cleared with cargoes consisted of 168 vessels,

aggregating 67,000 tons. Of the vessels, 81 were foreign. The roads are 165 miles long. As yet there is no railway. Fort de France is connected by regular monthly services with Bordeaux, St Nazaire, Marseilles, and Colon or Cayenne; there is also an English service connecting it with Southampton, and an American with New York. A cable connects Fort de France with the United States and with South America; a French cable was laid in 1890 between Martinique and Guadeloupe.

The following contemporary account of the eruption of Mont Pelée and the destruction of St Pierre in May 1902 was given in a letter to *The Standard* by Mr F. H. Watkins, the Commissioner of Montserrat. We quote from it in this article as giving the best available story of the disaster in the circumstances. From the geological point of view the conditions still remained to be investigated, but at the date when it was necessary for this volume to go to press no scientific report was to hand.

"St Pierre, nearly a mile in length, lay to the north-east of the island, in a cup-shaped valley enclosed by well-defined spurs of hills running down to the sea. It contained a fine cathedral, a bishop's palace, a governor's residence, and spacious barracks. Towering over the back of St Pierre rose the lofty, solitary, and majestic peak, Mont Pelée (4428 feet high). For three months prior to the great outburst signs of active disturbance were manifest, and on 25th April 1902, at 8 A.M., the neighbourhood was darkened as by a total eclipse of the sun. A shower of fine white ashes fell steadily for two hours, covering the district north of St Pierre to the depth of nearly half an inch. When the fall of ashes ceased the weather remained gloomy and calm, and the crater still continued to emit smoke. Excessive heat was experienced throughout the West Indies at this time. The volcano increased in activity until 2nd and 3rd May, when a tremendous outburst of fire and lava overwhelmed the large Guérin sugar estate situated to the north of St Pierre, burying, it is estimated, more than 150 persons. Although the fall of ashes did not cease and some of the inhabitants left for St Lucia, most persons in Martinique were in hopes that this was the culminating effort of Mont Pelée; and these hopes were heightened on Wednesday, 7th May, by the news that the St Vincent *soufrière* was in eruption, and by the thought that the Martinique volcano would thereby be relieved. After the destruction of the Guérin and other estates to the north the terrified and destitute labourers crowded into St Pierre to the number of 5000, thus adding considerably to those destined to meet their fate in the crowning act of destruction.

"The morning of 8th May dawned on St Pierre with nothing to distinguish it from the others of the previous week. With the exception of smoke issuing from Mont Pelée, no signs of impending disaster was apparent. Being Ascension Day, a *fête d'obligation*, the stores and shops were closed. In the roadstead lay about seventeen vessels of different sizes, among them being the *Roraima*, a fine steamer of the Quebec line. To the north, opposite what had been the Guérin estate, the cable-ship *Grappler* was busily restoring telegraphic communication with the northern islands. About seven o'clock the Scrutton steamer *Roddam* steamed up, but owing to some quarantine difficulties she was ordered to the place set apart for ships in quarantine, and one anchor had been let go about eight o'clock. By being thus moored slightly out of the full force of the eruption the *Roddam* probably escaped the fate of the other vessels. In a moment, without warning, came the awful catastrophe. Those who survived stated that the whole side of the mountain seemed to gape open, and from the fissure belched a lurid whirlwind of fire, wreathing itself into vast masses of flame as it descended with terrible speed upon the doomed town. Before the true extent of their peril could be grasped the fiery mass swept like a river over the town, and, pushing the very waters of the sea before it, set the ships ablaze. In a few seconds, when the flames of the volcano had spent themselves, molten masses of lava and ashes, accompanied by a dense sulphurous vapour, asphyxiated those who had escaped death by fire and shock. The sulphurous fumes hung over the town for some minutes before being dissipated by a faint breeze, and then succeeded utter darkness, illumined by the burning houses and ships, from which proceeded the shrieks of the few survivors. The *Grappler* was the first vessel to catch fire, and was soon seen to turn over and disappear, capsized probably by a sort of tidal wave caused by the force of the explosion. Some of those down in the hold and in the forepart of the *Roraima* managed to escape, but the steamer was burned to a mere shell. The *Roddam* alone escaped. Soon after her anchoring in the quarantine ground the eruption took place, and immediately afterwards molten lava fell on the ship. In a few minutes a second explosion took place, causing the sea to become a raging cauldron,

and this appears to have parted her anchor and caused her to drift. On board were fifteen labourers from Grenada looking after the cargo, seven of whom were roasted alive on the deck, and eight jumped overboard. The chief engineer, the first and second officers, and the supercargo lost their lives. Of forty persons who left St Lucia only ten or twelve returned alive, after taking nine hours to steam about 40 miles. Severely burned on his hands and face, Captain Freeman managed to bring his vessel to port.

"The French cruiser *Suchet* landed search parties at 1 A.M. on the 9th, but they were unable to penetrate into the town, which was still in flames. Some of the streets were lined with corpses. The only person in the town reported to be saved was a prisoner condemned for murder, who was discovered two days afterwards in his cell."

Consternation was caused not only in the West Indies, but in France and throughout the world, by this awful occurrence, and at first it was seriously suggested that the island should be totally evacuated, but no countenance was lent to this proposal by the French Government. Relief measures were at once undertaken, voluntary subscriptions raised, and it was considered probable in July 1902 that, with subsidies from the Government, the effects of the disaster might gradually be repaired. The material losses were estimated at £4,000,000; but, though St Pierre was destroyed, only one-tenth part of the island had been devastated, and the economic situation was fairly reassuring. The Bank of Martinique (which actually profited by the destruction of a large amount of its bank-notes) was sound, and in the absence of further eruptions or similar disasters the agricultural resources of the island bade fair to reassert themselves in time. During July, however, further activity was reported on the part of the volcano, and more destruction was done, and it remained doubtful what the future of the island was to be.

See HENRIQUE. *Les Colonies Françaises*. PARIS, 1890.—HENRI MOUET. *La Martinique*. PARIS, 1892.—LEVASSEUR. *La France*, t. ii. PARIS, 1893.—*L'Année Coloniale*, 1900. (P. L.)

Martinsburg, a city of West Virginia, U.S.A., capital of Berkeley county, in the Shenandoah valley, in the north-eastern part of the state, on the Baltimore and Ohio and the Cumberland Valley railways, at an altitude of 435 feet. It has railway repair works and varied manufactures, with (1900) a capital of \$1,633,024, 1105 wage-earners, and products valued at \$1,410,514. Population (1890), 7226; (1900), 7564, of whom 197 were foreign-born and 678 were negroes.

Martins Ferry, a city of Belmont county, Ohio, U.S.A., on the Ohio river, opposite Wheeling, West Virginia, in the eastern part of the state, at an altitude of 658 feet. It is on the Cleveland, Lorain and Wheeling, the Pennsylvania, the Wheeling and Lake Erie, and the Wheeling Terminal railways. Its manufactures, which are extensive, consist mainly of iron and steel goods. The city has also a large river trade. Population (1890), 6250; (1900), 7760, of whom 1033 were foreign-born and 253 were negroes.

Martin Vaz. See TRINIDAD (Brazil).

Martos, a town of Spain, in the province of Jaen, to the south-west of the town of that name. Its much-frequented sulphurous springs and bathing establishment have been improved. The local trade is almost exclusively agricultural, and in the neighbourhood much live stock is reared. Population (1887), 16,356; (1897), 17,086.

Martos, Christino (1830-1893), Spanish politician, was born at Granada 13th September 1820. He was educated in his native town, and at Madrid University, where his Radicalism soon got him into trouble, and he narrowly escaped being expelled for his share in student

riots and other demonstrations against the governments of Queen Isabella. He distinguished himself as a journalist on *El Tribuno*. He joined O'Donnell and Espartero in 1854 against a revolutionary cabinet, and shortly afterwards turned against O'Donnell to assist the Democrats and Progressists under Prim, Rivero, Castelar, and Sagasta in the unsuccessful movements of 1866, and was obliged to go abroad. His political career had not prevented Martos from rising into note at the bar, where he was very successful for forty years. After remaining abroad three years, he returned to Spain to take his seat in the Cortes of 1869 after the revolution of 1868. Throughout the revolutionary period he represented in cabinets with Prim, Serrano, and Ruiz Zorrilla, and lastly under King Amadeus, the advanced Radical tendencies of the men who wanted to give Spain a Democratic monarchy. After the abdication of Amadeus of Savoy Martos played a prominent part in the proclamation of the federal republic, in the struggle between the executive of that republic and the permanent committee of the Cortes, backed by the generals and militia, who very nearly put an end to the executive and republic in April 1873. When the republicans triumphed Martos retired into exile, and soon afterwards into private life. He reappeared for a few months after General Pavia's *coup d'état* in January 1874, to join a coalition cabinet formed by Marshal Serrano, with Sagasta and Ulloa. Martos again returned to the bar in May 1874, and quietly looked on when the restoration took place at the end of that year. He stuck to his Democratic ideals for some years, even going to Biarritz in 1881 to be present at a sort of republican congress presided over by Ruiz Zorrilla. Shortly afterwards Martos joined the dynastic Left organized by Marshal Serrano, General Lopez Dominguez, and Moret, Becerra, Balaguer, and other quondam Revolutionaries. He sat in several parliaments of the reign of Alphonso XII. and of the regency of Queen Christina, joined the dynastic Liberals under Sagasta, and gave Sagasta not a little trouble when the latter allowed him to preside over the House of Deputies. Having failed to form a rival party against Sagasta, Martos subsided into political insignificance, despite his great talent as an orator and debater, and died in Madrid 16th January 1893.

(A. E. H.)

Marx, Heinrich Karl (1818–1883), the greatest theorist of modern revolutionary Socialism, and head of the International Working Men's Association, was born on the 5th of May 1818 in Trèves (Rhenish Prussia). His father, a Jewish lawyer, in 1824 went over to Christianity, and he and his whole family were baptized as Christian Protestants. The son went to the high grammar school at Trèves, and from 1835 to the universities of Bonn and Berlin. He studied first law, then history and philosophy, and in 1841 took the degree of doctor of philosophy. In Berlin he had close intimacy with the most prominent representatives of the young Hegelians—the brothers Bruno and Edgar Bauer and their circle, the so-called "Freien." He at first intended to settle as a lecturer at Bonn University, but his Radical views made a university career out of the question, and he accepted work on a Radical paper, the *Rheinische Zeitung*, which expounded the ideas of the most advanced section of the Rhenish Radical *bourgeoisie*. In October 1842 he became one of the editors of this paper, which, however, after an incessant struggle with press censors, was suppressed in the beginning of 1843. In the summer of this year Marx married Jenny von Westphalen, the daughter of a high government official. Through her mother Jenny von Westphalen was a lineal descendant of the earl of Argyle, who was beheaded under

James II. She was a most faithful companion to Marx during all the vicissitudes of his career, and died on the 2nd of December 1881, he outliving her only fifteen months.

Already in the *Rheinische Zeitung* some Socialist voices had been audible, couched in a somewhat philosophical strain. Marx, though not accepting these views, refused to criticize them until he had studied the question thoroughly. For this purpose he went in the autumn of 1843 to Paris, where the Socialist movement was then at its intellectual zenith, and where he, together with Arnold Ruge, the well-known literary leader of Radical Hegelianism, was to edit a review, the *Deutsch-Französische Jahrbücher*, of which, however, only one number appeared. It contained two articles by Marx—a criticism of Bruno Bauer's treatment of the Jewish question, and an introduction to a criticism of Hegel's philosophy of the law. The first concluded that the social emancipation of the Jews could only be achieved together with the emancipation of society from Judaism, *i.e.*, commercialism. The second declared that in Germany no partial political emancipation was possible; there was now only one class from which a real and reckless fight against authority was to be expected, namely, the proletariat. But the proletariat could not emancipate itself except by breaking all the chains, by dissolving the whole constituted society, by recreating man as a member of the human society in the place of established states and classes. "Then the day of German resurrection will be announced by the crowing of the Gallican cock." Both articles thus relegated the solution of the questions then prominent in Germany to the advent of Socialism, and so far resembled in principle other Socialist publications of the time. But the way of reasoning was different, and the final words of the last quoted sentence pointed to a political revolution, to begin in France as soon as the industrial evolution had created a sufficiently strong proletariat. In contradistinction to most of the Socialists of the day, Marx laid stress upon the political struggle as the lever of social emancipation. In some letters which formed part of a correspondence between Marx, Ruge, Ludwig Feuerbach, and Michael Bakounine, published as an introduction to the review, this opposition of Marx to Socialistic "dogmatism" was enunciated in a still more pronounced form: "Nothing prevents us," he said, "from combining our criticism with the criticism of politics, from participating in politics, and consequently in real struggles. We will not, then, oppose the world like doctrinaires with a new principle: here is truth, kneel down here! We expose new principles to the world out of the principles of the world itself. We don't tell it: 'Give up your struggles, they are rubbish, we will show you the true war-cry.' We explain to it only the real object for which it struggles, and consciousness is a thing it *must* acquire even if it objects to it."

In Paris Marx met FRIEDRICH ENGELS, from whom the *Deutsch-Französische Jahrbücher* had two articles—a powerfully written outline of a criticism of political economy, and a letter on Carlyle's *Past and Present*. Engels, the son of a wealthy cotton-spinner, was born in 1820 at Barmen. Although destined by his father for a commercial career, he attended a classical school, and during his apprenticeship and whilst undergoing in Berlin his year's military service, he had given up part of his free hours to philosophical studies. In Berlin he had frequented the society of the "Freien," and had written letters to the *Rheinische Zeitung*. In 1842 he had gone to England, his father's firm having a factory near Manchester, and had entered into connexion with the Owenite and Chartist movements, as well as with German communists. He contributed to Owen's *New Moral World*

and to the Chartist *Northern Star*, gave up much of his abstract speculative reasoning for a more positivist conception of things, and took to economic studies. Now, in September 1844, on a short stay in Paris, he visited Marx, and the two found that in regard to all theoretical points there was perfect agreement between them. From that visit dates the close friendship and uninterrupted collaboration and exchange of ideas which lasted during their lives, so that even some of Marx's subsequent works, which he published under his own name, are more or less also the work of Engels. The first result of their collaboration was the book *Die heilige Familie oder Kritik der kritischen Kritik, gegen Bruno Bauer und Konsorten*, a scathing exposition of the perverseness of the high-sounding speculative Radicalism of Bauer and the other Berlin "Freie." By aid of an analysis, which though not free from exaggeration and a certain diffuseness, bears testimony to the great learning of Marx and the vigorous discerning faculty of both the authors, it is shown that the supposed superior criticism—the "critical criticism" of the Bauer school, based upon the doctrine of a "self-conscious" idea, represented by or incarnated in the critic—was in fact inferior to the older Hegelian idealism. The Socialist and working-class movements in Great Britain, France, and Germany are defended against the superior criticism of the "holy" Bauer family.

In Paris, where he had very intimate intercourse with Heinrich Heine, who always speaks of him with the greatest respect, and some of whose poems were suggested by Marx, the latter contributed to a Radical magazine, the *Vorwärts*, but in consequence of a request by the Prussian Government, nearly the whole staff of the magazine soon got orders to leave France. Marx now went to Brussels, where he shortly afterwards was joined by Engels. In Brussels he published his second great work, *La misère de la philosophie*, a sharp rejoinder to the *Philosophie de la misère ou contradictions économiques* of J. P. Proudhon. In this he deals with Proudhon, whom in the former work he had defended against the Bauers, not less severely than with the latter. It is shown that in many points Proudhon is inferior to both the middle-class economists and the Socialists, that his somewhat noisily proclaimed discoveries in regard to political economy were made long before by English Socialists, and that his main remedies, the "constitution of the labour-value" and the establishment of exchange bazaars, were but a repetition of what English Socialists had already worked out much more thoroughly and more consistently. Altogether the book shows remarkable knowledge of political economy. In justice to Proudhon, it must be added that it is more often his mode of speaking than the thought underlying the attacked sentences that is hit by Marx's criticism. In Brussels Marx and Engels also wrote a number of essays, wherein they criticized the German literary representatives of that kind of Socialism and philosophic Radicalism which was mainly influenced by the writings of Ludwig Feuerbach, and deduced its theorems or postulates from speculations on the "nature of man." They mockingly nicknamed this kind of Socialism "German or True Socialism," and ridiculed the idea that by disregarding historical and class distinctions a conception of society and Socialism superior to that of the English and French workers and theorists could be obtained. Some of these essays were published at the time, two or three, curiously enough, by one of the attacked writers in his own magazine; one, a criticism of Feuerbach himself, was in a modified form published by Engels in 1885, but others have remained in manuscript. They were at first intended for publication in two volumes as a criticism of post-Hegelian German philosophy, but the revolution

of 1848 postponed for a time all interest in theoretical discussions.

In Brussels Marx and Engels came into still closer contact with the Socialist working-class movement. They founded a German workers' society, acquired a local German weekly, the *Brüsseller Deutsche Zeitung*, and finally joined a communistic society of German workers, the "League of the Just," a secret society which had its main branches in London, Paris, Brussels, and several Swiss towns. For this league, which till then had adhered to the rough-and-ready communism of the gifted German workman Wilhelm Weitling, but which now called itself "League of the Communists," and gave up its leanings towards conspiracy and became an educational and propagandistic body, Marx and Engels at the end of 1847 wrote their famous pamphlet, *Manifest der Kommunisten*. It was a concise exposition of the history of the working-class movement in modern society according to their views, to which was added a critical survey of the existing Socialist and communist literature, and an explanation of the attitude of the communists towards the advanced opposition parties in the different countries. Scarcely was the manifesto printed when, in February 1848, the Revolution broke out in France, and "the crowing of the Gallican cock" gave the signal for an upheaval in Germany such as Marx had prophesied. After a short stay in France, Marx and Engels went to Cologne in May 1848, and there with some friends they founded the *Neue Rheinische Zeitung*, with the sub-title "An Organ of Democracy," a political daily paper on a large scale, of which Marx was the chief editor. They took a frankly revolutionary attitude, and directed their criticism to a great extent against the middle-class democratic parties, who, by evading all decisive issues, delayed the achievement of the upheaval. When in November 1848 the king of Prussia dissolved the National Assembly, Marx and his friends advocated the non-payment of taxes and the organization of armed resistance. Then the state of siege was declared in Cologne, the *Neue Rheinische Zeitung* was suspended, and Marx was put on trial for high treason. He was unanimously acquitted by a middle-class jury, but in May 1849 he was expelled from Prussian territory. He went to Paris, but was soon given the option of either leaving France or settling at a small provincial place. He preferred the former, and went to England. He settled in London, and remained there for the rest of his life.

At first he tried to reorganize the Communist League; but soon a conflict broke out in its ranks, and after some of its members had been tried in Germany and condemned for high treason, Marx, who had done everything to save the accused, dissolved the Communist League altogether. Nor was a literary enterprise, a review, also called the *Neue Rheinische Zeitung*, more successful; only six numbers of it were issued. It contained, however, some very remarkable contributions; and a series of articles on the career of the French Revolution of 1848, which first appeared there, was in 1895 published by Engels in book form under the title of *Die Klassenkämpfe in Frankreich von 1848* "by Karl Marx." Carlyle's *Latter Day Pamphlets*, published at that time, met with a very vehement criticism in the *Neue Rheinische Zeitung*. The endeavours of Ernest Jones and others to revive the Chartist movement were heartily supported by Marx, who contributed to several of the Chartist journals of the period, mostly, if not wholly, without getting or asking payment. He lived at this time in great financial straits, occupied a few small rooms in Dean Street, Soho, and all his children then born died very young. At length he was invited to write letters for the *New York Tribune*, whose staff consisted of

advanced democrats and Socialists of the Fourierist school. For these letters he was paid at the rate of a guinea each. Part of them, dealing with the Eastern Question and the Crimean war, were republished in 1897 (London, Sonnenschein). Some were even at the time reprinted in pamphlet form. The co-operation of Marx, who was determinedly anti-Russian, since Russia was the leading reactionary power in Europe, was obtained by David Urquhart and his followers. A number of Marx's articles were issued as pamphlets by the Urquhartite committees, and Marx wrote a series of articles on the diplomatic history of the 18th century for the Urquhartite *Free Press* (Sheffield and London, 1856-57). When in 1859 the Franco-Austrian war about Italy broke out, Marx denounced it as a Franco-Russian intrigue, directed against Germany on the one hand and the revolutionary movement in France on the other. He opposed those democrats who supported a war which in their eyes aimed at the independence of the Italian nation and promised to weaken Austria, whose superiority in Germany was the hindrance to German unity. Violent derogatory remarks directed against him by the well-known naturalist Karl Vogt, gave occasion to a not less violent rejoinder, *Herr Vogt*, a book full of interesting material for the student of modern history. Marx's contention, that Vogt acted as an agent of the Bonapartist clique, seems to have been well founded, whilst it must be an open question how far Vogt acted from dishonourable motives. The discussions raised by the war also resulted in a great estrangement between Marx and Ferdinand Lassalle. Lassalle had taken a similar view of the war to that advocated by Vogt, and fought tooth and nail for it in letters to Marx. In the same year, 1859, Marx published as a first result of his renewed economic studies the book *Zur Kritik der politischen Oekonomie*. It was the first part of a much larger work planned to cover the whole ground of political economy. But Marx found that the arrangement of his materials did not fully answer his purpose, and that many details had still to be worked out. He consequently altered the whole plan and sat down to rewrite the book, of which in 1867 he published the first volume under the title *Das Kapital*.

In the meantime, in 1864, the International Working Men's Association was founded in London, and Marx became in fact, though not in name, the head of its general council. All its addresses and proclamations were penned by him and explained in lectures to the members of the council. The first years of the International went smoothly enough. Marx was then at his best. He displayed in the International a political sagacity and toleration which compare most favourably with the spirit of some of the publications of the Communist League. He was more of its teacher than an agitator, and his expositions of such subjects as education, trade unions, the working day, and co-operation were highly instructive. He did not hurry on extreme resolutions, but put his proposals in such a form that they could be adopted by even the more backward sections, and yet contained no concessions to reactionary tendencies. But this condition of things was not permitted to go on. The anarchist agitation of Bakounine, the Franco-German war, and the Paris Commune created a state of things before which the International succumbed. Passions and prejudices ran so high that it proved impossible to maintain any sort of centralized federation. At the Congress of The Hague, September 1872, the general council was removed from London to New York. But this was only a makeshift, and in July 1876 the rest of the old International was formally dissolved at a conference held in Philadelphia. That its spirit had not passed away was shown by sub-

sequent international congresses, and by the growth and character of Socialist labour parties in different countries. They have mostly founded their programmes on the basis of its principles, but are not always in their details quite in accordance with Marx's views. Thus the programme which the German Socialist party accepted at its Congress in 1875 was very severely criticized by Marx. This criticism, reprinted in 1891 in the review *Die Neue Zeit*, is of great importance for the analysis of Marx's conception of Socialism.

The dissolution of the International gave Marx an opportunity of returning to his scientific work. He did not, however, succeed in publishing further volumes of *Das Kapital*. In order to make it, and especially the part dealing with property in land, as complete as possible, he took up, as Engels tells us, a number of new studies, but repeated illness interrupted his researches, and on the 14th of March 1883 he passed quietly away.

From the manuscripts he left Engels compiled a second and a third volume of *Das Kapital* by judiciously and elaborately using complete and incomplete chapters, rough copies and excerpts, which Marx had at different times written down. Much of the copy used dates back to the 'sixties, i.e., represents the work as at first conceived by Marx, so that, e.g., the matter published as the third volume was in the main written much earlier than the matter which was used for compiling the second volume. The same applies to the fourth volume. Although the work thus comprises the four volumes promised in the preface to the book, it can only in a very restricted sense be regarded as complete. In substance and demonstration it must be regarded as a torso. And it is perhaps not quite accidental that it should be so. Marx, if he had lived longer and had enjoyed better health, would have given the world a much greater amount of scientific work of high value than is now the case. But it seems doubtful whether he would have brought *Das Kapital*, his main work, to a satisfactory conclusion.

Das Kapital proposes to show up historically and critically the whole mechanism of capitalist economy. The first volume deals with the processes of producing capital, the second with the circulation of capital, the third with the movements of capital as a whole, whilst the fourth gives the history of the theories concerning capital. Capital is, according to Marx, the means of appropriating *surplus-value* as distinguished from ground rent (rent on every kind of terrestrial property, such as land, mines, rivers, &c., based upon the monopolist nature of such property). Surplus-value is created in the process of production only, it is this part of the value of the newly created product which is not given to the workman as a return—the *wage*—of the labour force he expended in working. If at first taken by the employer, it is in the different phases of economic intercourse split up into the profit of industrial enterprise, commercial or merchants' profit, interest, and ground rent. The value of every commodity consists in the labour expended on it, and is measured according to the time occupied by the labour employed on its production. Labour in itself has no value, being only the measure of value, but the labour-force of the workman has a value, the value of the means required to maintain the worker in normal conditions of social existence. Thus, in distinction to other commodities, in the determination of the value of labour-force, besides the purely economical, a *moral* and *historical* element enter. If to-day the worker receives a wage which covers the bare necessities of life, he is underpaid—he does not receive the real value of his labour-force. For the value of any commodity is determined by its socially necessary costs of production (or in this case, maintenance). "Socially necessary" means, further, that no more labour is embodied in a commodity than is required by applying labour-force, tools, &c., of average or normal efficiency, and that the commodity is produced in such quantity as is required to meet the effective demand for it. As this generally cannot be known in advance, the market value of a commodity only gravitates round its (abstract) value. But in the long run an equalization takes place, and for his further deductions Marx assumes that commodities exchange according to their value.

That part of an industrial capital which is employed for installations, machines, raw and auxiliary materials, is called by Marx *constant capital*, for the value of it or of its wear and tear reappears in equal proportions in the value of the new product. It is otherwise with labour. The new value of the product must by necessity be always higher than the value of the employed labour-force. Hence the capital employed in buying labour-force, i.e., in wages, is called *variable capital*. It is the tendency of capitalist production to reduce the amount spent in wages

and to increase the amount invested in machines, &c. For with natural and social, legal and other limitations of the working day, and the opposition to unlimited reduction of wages, it is not possible otherwise to cheapen production and beat competition. According to the proportion of constant to variable capital, Marx distinguishes capitals of *lowest average* and *highest composition*, the highest composition being that where proportionately the least amount of variable (wages) capital is employed.

The ratio of the wages which workmen receive to the surplus-value which they produce Marx calls the *rate of surplus-value*; that of the surplus-value produced to the whole capital employed is the *rate of profit*. It is evident, then, that at the same time the rate of surplus-value can increase and the rate of profit decrease, and this in fact is the case. There is a continuous tendency of the rates of profit to decrease, and only by some counteracting forces is their decrease temporarily interrupted, protracted, or even sometimes reversed. Besides, by competition and movement of capitals the rates of profit in the different branches of trade are pressed towards an *equalization* in the shape of an *average rate of profits*. This average rate of profits, added to the actual cost price of a given commodity, constitutes its *price of production*, and it is this price of production which appears to the empirical mind of the business man as the value of the commodity. The real law of value, on the contrary, disappears from the surface in a society where, as to-day, commodities are bought and sold against money and not exchanged against other commodities. Nevertheless, according to Marx, it is also to-day this law of value ("labour-value") which in the last resort rules the prices and profits.

The tendency to cheapen production by increasing the relative proportion of constant capital—the fixed capital of the classical economist plus that portion of the circulating capital which consists of raw and auxiliary materials, &c.—leads to a continuous increase in the size of private enterprises, to their growing concentration. It is the larger enterprise that beats and swallows the smaller. The number of dependent workmen—"proletarians"—is thus continually growing, whilst employment only periodically keeps pace with their number. Capital alternately attracts and repels workmen, and creates a constant surplus-population of workmen—a *reserve-army* for its requirements—which helps to lower wages and to keep the whole class in economic dependency. A decreasing number of capitalists usurp and monopolize all the benefits of industrial progress, whilst the mass of misery, of oppression, of servitude, of depravation, and of exploitation increases. But at the same time the working class continuously grows in numbers, and is disciplined, united, and organized by the very mechanism of the capitalist mode of production. The centralization of the means of production and the socialization of the mode of production reach a point where they will become incompatible with their capitalist integument. Then the knell of capitalist private property will have been rung. Those who used to expropriate will be expropriated. Individual property will again be established, based upon co-operation and common ownership of the earth and the means of production produced by labour.

These are the principal outlines of *Das Kapital*. Its purely economic deductions are dominated throughout by the *theory of surplus-value*. Its leading sociological principle is the *materialist conception of history*. This theory is in *Das Kapital* only laid down by implication, but it has been more connectedly explained in the preface of *Zur Kritik* and several works of Engels. According to it the material basis of life, the manner in which life and its requirements are produced, determines in the last instance the social ideas and institutions of the time or historical epoch, so that fundamental changes in the former produce in the long run also fundamental changes in the latter. A set of social institutions answers to a given mode of production, and periods where the institutions no longer answer to the mode of production are periods of social revolution, which go on until sufficient adjustment has taken place. The main *subjective* forces of the struggle between the old order and the new are the *classes* into which society is divided after the dissolution of the communistic or semi-communistic tribes and the creation of states. And as long as society is divided into classes a class war will persist, sometimes in a more latent or disguised, sometimes in a more open or acute form, according to circumstances. In advanced capitalist society the classes between whom the decisive war takes place are the capitalist owners of the means of production and the non-propertied or wage-earning workers, the "proletariat." But the proletariat cannot free itself without freeing all other oppressed classes, and thus its victory means the end of exploitation and political repression altogether. Consequently the state as a repressive power will die out, and a free association will take its place.

Almost from the first *Das Kapital* and the publications of Marx and Engels connected with it have been subjected to all kinds of criticisms. The originality of its leading ideas has been disputed, the ideas themselves have been declared to be false or

only partially true, and consequently leading to wrong conclusions; and it has been said of many of Marx's statements that they are incorrect, and that many of the statistics upon which he bases his deductions do not prove what he wants them to prove. In regard to the first point, it must be conceded that the *dissecta membra* of Marx's value theory and of his materialist conception of history are already to be found in the writings of former Socialists and sociologists. It may even be said that just those points of the Marxist doctrine which have become popular are in a very small degree the produce of Marx's genius, and that what really belongs to Marx, the methodical conjunction and elaboration of these points, as well as the finer deductions drawn from their application, are generally ignored. But this is an experience repeated over and over again in the history of deductive sciences, and is quite irrelevant for the question of Marx's place in the history of Socialism and social science.

It must further be admitted that in several places the statistical evidence upon which Marx bases his deductions is insufficient or inconclusive. Moreover, and this is one of the most damaging admissions, it repeatedly happens that he points out all the phenomena connected with a certain question, but afterwards ignores some of them and proceeds as if they did not exist. Thus, *e.g.*, he speaks at the end of the first volume, where he sketches the historical tendency of capitalist accumulation, of the decreasing number of magnates of capital as of an established fact. But all statistics show that the number of capitalists does not decrease, but increase; and in other places in *Das Kapital* this fact is indeed fully admitted, and even accentuated. Marx was, as the third volume shows, also quite aware that limited liability companies play an important part in the distribution of wealth. But he leaves this factor, too, quite out of sight, and confuses the concentration of private enterprises with the centralization of fortunes and capitals. By these and other omissions, quite apart from developments he could not well foresee, he announces a coming evolution which is very unlikely to take place in the way described.

In this and in other features of his work a *dualism* reveals itself which is also often observable in his actions in life—the alternating predominance of the spirit of the scholar and the spirit of the Radical revolutionary. Marx originally entitled his great social work *Criticism of Political Economy*, and this is still the sub-title of *Das Kapital*. But the conception of *critic* or *criticize* has with Marx a very pronounced meaning. He uses them mostly as identical with fundamentally opposing. Much as he had mocked the "critical criticism" of the Bauers, he is in this respect yet of their breed and relapses into their habits. He retained in principle the Hegelian dialectical method, of which he said that in order to be rationally employed it must be "turned upside down," *i.e.*, put upon a materialist basis. But as a matter of fact he has in many respects contravened against this prescription. Strict materialist dialectics cannot conclude much beyond actual facts. Dialectical materialism is revolutionary in the sense that it recognizes no finality, but otherwise it is necessarily positivist in the general meaning of that term. But Marx's opposition to modern society was fundamental and revolutionary, answering to that of the proletarian to the *bourgeois*. And here we come to the main and fatal contradiction of his work. He wanted to proceed, and to a very great extent did proceed, scientifically. Nothing was to be deduced from preconceived ideas; from the observed evolutionary laws and forces of modern society alone were conclusions to be drawn. And yet the final conclusion of the work, as already noted, is a preconceived idea; it is the announcement of a state of society logically opposed to the given one. Imperceptibly the dialectical movement of *ideas* is substituted for the dialectical movement of facts, and the real movement of facts is only considered so far as is compatible with the former. Science is violated in the service of speculation. The picture given at the end of the first volume answers to a conception arrived at by speculative socialism in the 'forties. True, Marx calls this chapter "the historical tendency of capitalist accumulation," and "tendency" does not necessarily mean realization in every detail. But on the whole the language used there is much too absolute to allow of the interpretation that Marx only wanted to give a speculative picture of the goal to which capitalist accumulation would lead if unhampered by Socialist counteraction. The epithet "historical" indicates rather that the passage in question was meant to give in the main the true outline of the forthcoming social revolution. We are led to this conclusion also by the fact that, in language which is not in the least conditional, it is there said that the change of capitalist property into social property will mean "only the expropriation of a few usurpers by the mass of the people." In short, the principal reason for the undeniable contradictions in *Das Kapital* is to be found in the fact that where Marx has to do with details or subordinate subjects he mostly notices the important changes which actual evolution had

brought about since the time of his first Socialist writings, and thus himself states how far their presuppositions have been corrected by facts. But when he comes to general conclusions, he adheres in the main to the original propositions based upon the old uncorrected presuppositions. Besides, the complex character of modern society is greatly underestimated, so that, e.g., such important features as the influence of the changes of traffic and aggregation on modern life are scarcely considered at all; and industrial and political problems are viewed only from the aspect of class antagonism, and never under their administrative aspect. With regard to the theory of surplus-value and its foundation, the theory of labour-value, so much may be safely said that, its premisses accepted, it is most ingeniously and most consistently worked out. And since its principal contention is in any case so far true that the wage-earning workers as a whole produce more than they receive, the theory has the great merit of demonstrating in an admirably lucid way the relations between wages and surplus-produce and the growth and movements of capital. But the theory of labour-value as the determining factor of the exchange or market value of commodities can with justification be disputed, and is surely not more true than those theories of value based on social demand or utility. Marx himself, in placing in the third volume what he calls the *law of value* in the background and setting out the formation of the "price of production" as the empirical determinant of prices in modern society, justifies those who look upon the conception of labour-value as an abstract formula which does not apply to individual exchanges of commodities at all, but which only serves to show an imagined typical example of what in reality to-day is only true with regard to the production of the whole of social wealth. Thus understood, the conception of labour-value is quite unobjectionable, but it loses much of the significance attributed to it by most of the disciples of Marx and occasionally by Marx himself. It is a means of analysing and exemplifying surplus labour, but quite inconclusive as to the proof of the surplus value, or as an indication of the degree of the exploitation of the workers. This becomes the more apparent the more the reader advances in the second and third volumes of *Das Kapital*, where commercial capital, money capital, and ground rent are dealt with. Though full of fine observations and deductions, they form, from a revolutionary standpoint, an anti-climax to the first volume. It is difficult to see how, after all that is explained there on the functions of the classes that stand between industrial employers and workers, Marx could have returned to those sweeping conclusions with which the first volume ends.

The great scientific achievement of Marx lies, then, not in these conclusions, but in the *details* and yet more in the *method* and *principles* of his investigations in his *philosophy of history*. Here he has, as is now generally admitted, broken new ground and opened new ways and new outlooks. Nobody before him had so clearly shown the *rôle* of the productive agencies in historical evolution; nobody so masterfully exhibited their great determining influence on the forms and ideologies of social organisms. The passages and chapters dealing with this subject form, notwithstanding occasional exaggerations, the crowning parts of his works. If he has been justly compared with Darwin, it is in these respects that he ranks with that great genius, not through his value theory, ingenious though it be. With the great theorist of biological transformation he had also in common the indefatigable way in which he made painstaking studies of the minutest details connected with his researches. In the same year as Darwin's epoch-making work on the origin of species there appeared also Marx's work *Zur Kritik der politischen Ökonomie*, where he explains in concise sentences in the preface that philosophy of history which has for the theory of the transformation or evolution of social organisms the same significance that the argument of Darwin had for the theory of the transformation of biological organisms.

The main writings of Karl Marx and Friedrich Engels are as follows (we give only the titles of the original works and of their English translations):—1. Of KARL MARX alone: *La misère de la philosophie, réponse à La philosophie de la misère de M. Proudhon*, Paris, 1847, new edition, 1892; English edition, *The Poverty of Philosophy*, London, 1900. *Lohnarbeit und Kapital*, pamphlet, written 1848, new edition, Berlin, 1891; English edition, *Wage-Labour and Capital*, London, 1900. *Die Klassenkämpfe in Frankreich, 1848 to 1850*, Berlin, 1895. *Der achtzehnte Brumaire des Louis Bonaparte*, New York, 1852, 3rd edition, Hamburg, 1889; English edition, New York, 1889. *Enthüllungen über den Kölner Kommunistenprozess*, Basel, 1852; new edition, Zürich-Berlin, 1885. *European Revolutions and Counter-Revolution* (reprints from the *New York Tribune*, 1851-1852), London, 1896. *The Eastern Question* (reprints from the *New York Tribune*, 1853-56), London, 1898. *Zur Kritik der politischen Ökonomie*, Berlin, 1859; new edition, Stuttgart, 1897. *Herr Vogt*, London, 1860. *Inaugural Address of the Inter-*

national Working Men's Association, London, 1864. *Value, Price, and Profit*; written 1865, published London, 1898. *Das Kapital, Kritik der politischen Ökonomie*, 3 vols., Hamburg, 1867, 1885, and 1895; English edition of 1st vol. 1886. *The Civil War in France*, 1871, London, 1871; new edition, 1894. *L'Alliance de la démocratie socialiste*, London, 1873. Articles printed or reprinted in *Rheinische Zeitung*, 1842-43; *Deutsch-Französische Jahrbücher*, Paris, 1844; *Das Westphälische Dampfboot*, Bielefeld und Paderborn, 1845-48; *Der Gesellschaftsspiegel*, Elberfeld, 1846; *Deutsche Brüsseler Zeitung*, Bruxelles, 1847; *Neue Rheinische Zeitung* (daily), Cologne, 1848-49 (monthly), Hamburg, 1850. *The People*, London, 1852-58; *The New York Tribune*, New York, 1853-60; *The Free Press*, Sheffield and London, 1856-57; *Das Volk*, London, 1859; *Der Vorbote*, Geneva, 1866-75; *Der Volkstaat*, Leipzig, 1869-76; *Die Neue Zeit*, Stuttgart, 1883, *sqq.*; *Sozialistische Monatshefte*, Berlin, 1895, *sqq.*—2. Of FRIEDRICH ENGELS alone: *Die Lage der arbeitenden Klassen in England*, Leipzig, 1845, new edition, Stuttgart, 1892; English edition, London, 1892. *Zur Wohnungsfrage*, Leipzig, 1873-74; new edition, Zürich-Berlin, 1887. *Herrn Eugen Dührings Umwälzung der Wissenschaft*, Leipzig, 1877; 3rd edition, Stuttgart, 1894. Three chapters of the first-named are published in English under the title *Socialism, Utopian and Scientific*, London, 1892. *Der Ursprung des Eigenthums, der Familie und des Staates*, Zürich and Stuttgart, 1885 and 1892. *Ludwig Feuerbach und der Ausgang der Klassischen deutschen Philosophie*, Stuttgart, 1886. Introductions to most of the posthumous works of K. Marx and articles in the same periodicals as Marx.—3. Of KARL MARX and FRIEDRICH ENGELS together: *Die Heilige Familie oder Kritik der Kritischen Kritik*, Frankfurt, 1845. *Manifest der Kommunistischen Partei*, London, 1848; English edition, 1848 and 1888.—4. With regard to Marx generally, his theory and his school, see J. STAMHAMMER, *Bibliographie des Sozialismus und Kommunismus*, Jena, 1893; and Th. G. MASARYK, *Die philosophischen und soziologischen Grundlagen des Marxismus*, Vienna, 1899. Much biographical and bibliographical information on Marx and Engels is to be found in Dr FRANZ MEHRING, *Geschichte der deutschen Sozialdemokratie*, Stuttgart, 1897-98, and in the collection, edited also by Dr Fr. MEHRING, *Aus dem literarischen Nachlass von Karl Marx, Friedrich Engels und Ferdinand Lassalle*, Stuttgart, 1902. Of the criticisms of Marx's economics, one of the most comprehensive is E. VON BOEHM-BAWERK's *Karl Marx and the Close of his System*, London, 1898. Marx's historic theory is, apart from Masaryk, very exhaustively analysed by R. STAMMLER in *Wirtschaft und Recht*, Leipzig, 1896. (E. EN.)

Maryborough, town, Queensland, Australia, in the county of March, 25 miles from the mouth of the river Mary, about 180 miles north of Brisbane by rail. It is the port of shipment for a wide agricultural district yielding maize and sugar, and also for the Gympie goldfield. Large smelting works are 5 miles distant, in which ore from all the states is treated. There are also foundries and a large shipbuilding yard. Population (1891), 9700; (1901), 10,159.

Maryborough, a borough of Victoria, Australia, in the county of Talbot, 112 miles by rail north-west of Melbourne. It is an important railway centre, and has extensive railway workshops. The gold-mining of the district is deep alluvial. Population (1901), 5623.

Maryland, one of the original states of the American Union, bounded on the N. by Pennsylvania and Delaware, on the E. by Delaware and the Atlantic Ocean, and on the S. and W. by Virginia and West Virginia. It is divided into three physiographic areas known as the Coastal Plain, the Piedmont Plateau, and the Appalachian Region. The Coastal Plain, embracing about 5000 square miles, represents in its formations the various epochs of geological history from the late Jurassic or early Cretaceous to the present time. The trough of the Chesapeake Bay was cut across the Coastal Plain by the predecessor of the present Susquehanna river, the bay being only the submerged lower valley of that stream. The Piedmont Plateau borders this plain on the west, and, extending to the base of the Catoctin Mountain, includes about 2500 square miles. The most widely extended formation of this area is the gneiss, enfolded with which are quartz-schist and marble bands and several types of

igneous rocks. The Appalachian Region extends from the Piedmont Plateau to the western limits of the state, and comprises about 2000 square miles. This region is divided into three distinct physiographic districts based upon clearly defined geological differences, *i.e.*, an eastern (Blue Ridge and Great Valley), a central (Alleghany Ridges), and a western (Alleghany Plateau) division. Dr William Bullock Clark says the "Great Appalachian Valley, commonly known in Maryland as the Hagerstown Valley, is underlain by the Shenandoah limestone of late Cambrian and early Silurian age, which also outcrops to the east of the Catoctin Mountain in the Frederick Valley. Beyond the Great Valley there is a succession of sharp ridges and deep valleys formed of the folded sediments of Silurian, Devonian, and Carboniferous age, the Silurian and Devonian rocks predominating in the eastern ridges, and the Devonian and Carboniferous in the west. The coal deposits of the Carboniferous occupy a succession of troughs to the west of Cumberland, and are the most important geological deposits from a commercial standpoint within the limits of the state."

The total area of Maryland is 12,210 square miles, of which 2350 are water. The total land area is 9860 square miles, and is divided among the counties of the state as follows:—

County.	Square Miles.	County.	Square Miles.
Alleghany	442	Harford	388
Anne Arundel	425	Howard	240
Baltimore	656	Kent	281
Baltimore City	30	Montgomery	490
Calvert	222	Prince George's	482
Caroline	320	Queen Anne's	376
Carroll	437	St Mary's	372
Cecil	360	Somerset	362
Charles	451	Talbot	286
Dorchester	608	Washington	458
Frederick	662	Wicomico	365
Garrett	660	Worcester	487

Population.—The figures of the decennial census from 1880 to 1900 are as follows for the whole state:—

Year.	Population.	Increase.	Percentage of Increase.
1880	934,943	154,049	19.7
1890	1,042,390	107,447	11.5
1900	1,188,044	145,654	14.1

In 1900 the total white population amounted to 952,424, of whom 473,119 were male and 479,305 female. The total negro population at the same date was 235,064, of whom 115,617 were male and 119,447 female. There were also 544 Chinese, 9 Japanese, and 3 Indians taxed. The native-born population amounted to 1,094,110; the foreign-born to 93,934. There were within the state only five cities with a population in 1900 of over 6000—namely, Baltimore, 508,957; Cumberland, 17,128; Hagerstown, 13,591; Frederick, 9296; and Annapolis, 8525. The urban population was 46.9 per cent. of the total population. The average number of persons to the square mile was 120.7 in 1900, as compared with 105.7 in 1890. In 1901 the registered voters of the state (males twenty-one years of age and over) numbered 272,231, as against 293,389 voters in 1900.

Education.—Maryland has an excellent system of free public schools supported by state, county, and municipal taxation. In 1899 the number was as follows:—Schools in Baltimore city, 185; in the counties, 2334; pupils in Baltimore city, 80,146; in the counties, 142,227; teachers in Baltimore city, 1802; in the counties, 3314; cost of maintenance in Baltimore city, \$1,218,734; in the counties, \$1,469,063. Total number of schools, 2519; total number of pupils, 222,373; total number of teachers, 5116; total cost, \$2,687,797. The State Normal School, St John's College, Western Maryland College, Maryland Agricultural College, Washington College, Frederick School for the Deaf and Dumb, St Mary's Female Seminary, Charlotte Hall Academy, and Maryland Institute, with a total of 1353 students and 110 teachers, received from the state in 1899 an aggregate of \$139,400. Thirteen other schools and academies, with a total of 1289 students, received aid from the state to the amount of \$8900. The chief educational institution of the state is the Johns Hopkins University (including a graduate school, a college, and a medical school), which had (in 1900) 131 professors and instructors and 651 enrolled students.

Also situated in Baltimore city are the Woman's College, the City College, the University of Maryland (including a law school, a medical school, and a school of dental surgery), the College of Physicians and Surgeons, College of Dental Surgery, Baltimore Medical College, &c.

Libraries.—The Peabody Library in Baltimore contains 135,000 volumes, designed especially for students, and is well catalogued. It is open daily, without charge. The Enoch Pratt Free Library, also in Baltimore (income \$50,000 per annum), is a free circulating library, with branches throughout the city, and numbers upwards of 200,000 volumes. There are also in Baltimore the library of the Johns Hopkins University, 94,000 volumes; the Maryland Historical Society's Library, 30,000 volumes; the New Mercantile Library, 50,000 volumes; the Bar Library, 17,000 volumes; the Medical and Chirurgical Library, 14,000 volumes; and the library of the Maryland Institute, 23,000 volumes. The State Library at Annapolis contains 60,000 volumes.

Charities.—The Maryland Hospital for the Insane at Catonsville treats and cares for an average of 535 patients, and reports 4 per cent. of cures of those treated. The second hospital for the insane, situated in Sykesville, annually treats an average of 206 patients. These two institutions received from the state \$50,000 in 1900. The State Lunacy Commission reports a total of 2531 insane confined in almshouses, gaols, penitentiary, public and private institutions, in 1899. The Sheppard and Enoch Pratt Hospital for Mental and Nervous Diseases was founded by Moses Sheppard, and became the residuary legatee of the estate of Enoch Pratt. The design of the founder, based on the belief that many cases of curable insanity become chronic through lack of proper care and treatment, was for a home treatment on the principle of non-restraint, and the removal of all features suggestive of an asylum. By reason of the plan, the scope is necessarily limited. From 1892 to 1899, 553 patients were admitted and 462 discharged, of whom 99 were cured and 166 greatly improved. The Maryland Asylum and Training School for Feeble-Minded, at Owings Mills, cares for an average of 100 annually. A large number of the leading charitable institutions—hospitals, asylums, and training schools—are private corporations, which are made the almoners of the state's charity by annual legislative appropriations, while they are supported in part by endowments of their own and by private subscription. In 1900 the state gave \$263,000 to 48 institutions of this character.

Penal Institutions.—The new penitentiary, completed at a cost of \$1,000,000, is a model of its kind. Its inmates number 918 men and 48 women. The institution is self-supporting, and annually yields a surplus to the state treasury. In addition to learning trades, all convicts are allowed to work overtime, and the amount thus made is credited to them when they leave the institution. In 1899 the convicts earned for themselves in this way \$22,697. The Maryland House of Correction, a prison for minor offences, is supported by an annual legislative appropriation of \$25,000 and the labour of the inmates. The average number of committals yearly is 1483. The House of Refuge at Baltimore had, in 1900, 223 boys committed. Manual training is given to all inmates. The female House of Refuge had 127 inmates, who are taught useful occupations, and are supplied with homes at the expiration of their detention.

Banks.—The national banks presented the following statement of their condition in September 1900:—

	Number.	Capital Stock paid in.	Individual Deposits.
Counties	53	\$4,014,400	\$13,912,473
Baltimore	19	11,108,260	29,029,006

Seventeen state banks reported in 1900 shares of stock assessed at \$1,718,130, and owned real estate valued at \$226,442. The aggregate deposits of the 35 savings banks amounted in 1899 to \$56,140,168. The real estate owned by these banks was assessed at \$1,045,271. The bank clearances in Baltimore city amounted in 1887 to \$659,346,471, rose in 1896 to \$720,089,733, and in 1899 to \$1,209,777,742.

Agriculture.—The total number of farms in 1900 was 46,012; occupied by owners, 30,565, occupied by tenants, 15,447. The total value of farms was \$204,645,407. Total acreage of farms, 5,170,075; improved, 3,516,352; unimproved, 1,653,723. Value of implements, &c., \$8,611,220; live stock, \$20,855,877. Value of farm products (1899), \$43,823,419. Horses (1900), 179,486; mules, 19,325; neat cattle on farms, 292,646; sheep, 194,076; swine, 359,812. Amount paid to farm labourers, \$5,715,520.

Coal Mining.—The total production of coal in the state in 1901 was 4,481,403 long tons, and the value of mines and equipments was \$20,000,000; paid for labour, \$1,464,826. In 1898 the shipments of coal by the companies operating in George's Creek region amounted to 4,120,870 tons, and the number of men employed was 4651.

Oysters.—During the season of 1898–99 the quantity of oysters officially inspected was 5,547,793 bushels, but this did not include all the products of the beds of Chesapeake Bay.

Tobacco.—The tobacco received for inspection at the state warehouses in 1898 amounted to 36,219 hogsheads.

Manufactures.—The number of manufacturing establishments reporting in 1900 was 9880, with an aggregate capital of \$163,422,260. Number of labourers, 108,361. Total wages, \$38,761,551. Salaried employes, 7589; salaries paid, \$7,383,263. Cost of materials used, \$144,639,680. Value of products, \$242,752,990. The greater part of the manufacturing is carried on in Baltimore. There were in this city 6361 manufacturing establishments, with a capital of \$117,869,175, products valued at \$161,945,811, and 79,084 wage-earners (exclusive of salaried officials, clerks, &c.), who received wages amounting to \$29,304,520.

Commerce.—The size of the foreign commerce is seen in the following statistics relating to Baltimore city, the chief port:—

Exports for the year ending 30th June 1901 . . .	\$106,239,081
Imports " " " " . . .	18,899,473
Custom house receipts, 1898 . . .	\$1,870,038
" " " " 1899 . . .	2,549,725
Internal revenue collections, 1898 . . .	6,657,360
" " " " 1899 . . .	8,667,652
Immigration through Baltimore, 1898 . . .	12,853
" " " " 1899 . . .	20,233

Finances.—The funded debt amounted on 1st January 1899 to \$6,009,326. As an offset to this the state held interest-bearing securities and cash to the credit of the sinking funds amounting in value to \$3,121,283, leaving the net debt \$2,888,043. The value of the property assessed for taxation in 1899 was \$611,539,646. In 1890 this value was \$482,184,824.

History, &c.—Since 1895 the two great parties—Democratic and Republican—have been nearly equal in numbers, and the control of the state government is sometimes with one and sometimes with the other. The statutory law of the state was codified in 1888, and a supplement to the code, embracing the subsequent statutes, was adopted in 1900. The most important work relating to the history of the state is the Maryland Archives, published by the Maryland Historical Society under the authority of the legislature (1882 to date). Twenty volumes have so far appeared, containing principally the proceedings of the executive and legislative departments in the 17th and 18th centuries. The annual reports of the Maryland Geological Survey, beginning in 1897, convey the result of much original investigation relating to the soils and the physical features.

(W. T. B.)

Maryport, market-town and seaport in the Cocker-mouth parliamentary division of Cumberland, England, at the mouth of the river Ellen, 25 miles west-south-west of Carlisle by rail. The harbour is easy of access, and with the river offers 3800 feet of quayage. In 1892 it became an independent port with Workington, Whitehaven, and Millom subordinate to it. In 1888, 1459 vessels of 239,981 tons entered and 1456 of 244,501 tons cleared; in 1898, 3171 vessels of 606,922 tons entered and 3164 of 612,022 tons cleared. The registered shipping in 1898 totalled 26 vessels of 17,826 tons. Steel rails and coal are exported; timber, iron-ore, and grain imported. Population (1891), 12,410; (1901), 11,896.

Mascara, a town of Algeria, department of Oran, 60 miles south-east of the town of Oran. The principal industry is wine, for which it has a high repute. Over 3000 acres in the neighbourhood have been planted with vines, and, notwithstanding an attack of phylloxera, the area of vineyards is extending. Population (1886), 15,400; (1896), 20,410, of whom 10,104 were French.

Maseru. See BASUTOLAND.

Mashonaland. See RHODESIA (SOUTH).

Mason City, a city of Iowa, U.S.A., capital of Cerro Gordo county, on the Shell Rock river, in the northern part of the state, at an altitude of 1132 feet. It is on the Chicago, Milwaukee, and St Paul, the Iowa Central, the Mason City and Fort Dodge, the Mason City and Clear Lake, and the Chicago and North-western railways. It is in a rich agricultural region, for which it serves as a collecting and distributing point. Population

(1890), 4007; (1900), 6746, of whom 914 were foreign-born and 55 were negroes.

Massa, a town, bishop's see, and capital of the province of Massa and Carrara, Tuscany, Italy, situated near the Mediterranean coast, 27 miles north-west of Pisa by rail. Like Carrara, it is a centre of the marble industry, in which some 1100 men were employed in 1898. It also carries on the manufacture of cotton, silk, and tobacco. Population (1881), 16,246; (1901), 26,325.

Massachusetts, one of the New England states of the American Union, bounded on the N. by New Hampshire and Vermont, on the W. by New York, on the S. by Connecticut and Rhode Island, and on the E. by the Atlantic.

Population.—The population in 1890 was 2,238,943, and in 1900 it was 2,805,346, an increase during 1890–1900 of 25·2 per cent. With the exception of Rhode Island, it is the most densely settled state in the Union, the average number of persons to the square mile at the census of 1900 being 348·9, and the urban population being 76·0 per cent. of the total population. In 1900 females constituted 51·3 per cent. of the total population. Only 1·3 per cent. of the population was coloured. The percentage of the population that was foreign-born in 1885 was 27·13, and in 1900 it was 30·2. Ireland contributed the largest proportion of the foreign-born population, although since 1875 the numbers born in that country and living in Massachusetts have increased but slowly. The Irish-born proportion of the population of the state, which in 1875 was 14 $\frac{1}{2}$ per cent., was in 1895, 10 $\frac{1}{2}$ per cent. In 1895 a very nearly similar percentage were immigrants from British America. These were chiefly of French origin, and large numbers of them found employment in the textile industries. Other countries which in 1895 contributed more than 15,000 each to the population were England, Sweden and Norway, Germany, Scotland, and Italy, in the order named. During the period 1885–90 the largest proportional increase from any foreign country was from Italy. For the year ending 30th September 1899 the number of passengers arriving from foreign ports was 72,682. Of these there were aliens from the Dominion of Canada to the number of 24,084, and aliens from transatlantic ports to the number of 20,065. A large part of the transatlantic immigrants pass speedily to permanent homes in the West, but by far the greater part of the Canadian influx remains, and may become citizens. According to the census of 1900, there were 33 incorporated cities in Massachusetts, of which 8 had between 12,000 and 20,000 inhabitants; 5 between 20,000 and 25,000; 10 between 25,000 and 50,000; 7 between 50,000 and 100,000; and 3 more than 100,000 inhabitants, namely, Boston (560,892), Worcester (118,421), and Fall River (104,863). In 1890 the urban population (classing as such all persons in places of more than 8000 inhabitants) was 69·9 per cent. of the total population; in 1900 it was 76 per cent. The aggregate number of state, city, and town poor (including the insane) remaining in institutions was, on 30th September 1899, 12,795. The total number of prisoners was 6772, a reduction of 679 from the year before. The birth-rate in 1895 was 27·02 per thousand, and was the highest in any census year since 1860. In 1898 it is estimated to have been 27·37. Of all the children born in Massachusetts in 1898, 32·35 per cent. were of native-born parents, 48·24 per cent. were of foreign-born parents, 19·02 per cent. were of parents of whom one was foreign-born, and 39 per cent. were of unreported parentage. The death-rate in 1895 was 19·01 per thousand, which is less than in any census year since 1870. The death-rate of 1900 was 17·7.

Politics.—Since 1820 the payment of at least a poll-tax had been one of the pre-requisites to the exercise of the suffrage, but this requirement was annulled by a constitutional amendment adopted by the people in 1891. An educational test is exacted for the privilege of voting, every voter being required to read the constitution of the commonwealth in the English language, and to write his name. The number of legal voters in 1895 was 560,802. In the Presidential election of 1896, when an unprecedentedly large vote was cast, the number of voters registered was 490,554, or nearly 20 per cent. of the population, and of these 401,568 actually voted, or nearly 82 per cent. Massachusetts is one of the only two states in the Union in which elections for state officers are now held annually. In 1896 two amendments to the constitution, establishing biennial elections of state officers and of members of the general court, were defeated by a large majority. At all elections official ballots are furnished, and are marked and cast by the voter under provisions of the so-called Australian Ballot Act, which ensure absolute secrecy. A limited suffrage was conferred upon women in 1879. At the present time every female citizen having the qualifications of a male voter may vote in the

city and town elections for members of the school committee. This privilege has not been very generally exercised. In 1899 there were 36,110 registered women voters, and of these only 35 $\frac{1}{2}$ per cent. voted, whereas of the registered male voters 77 $\frac{1}{2}$ per cent. voted. In the city of Boston, however, where much interest was felt in the election, 67 $\frac{3}{10}$ of the registered women voted, a larger proportion than that of men who voted at the state election a month earlier. Efforts are annually made to extend female suffrage to the election of other municipal officers and to state officers, but these efforts have not proved successful. In 1895 all persons qualified to vote for the school committee were given an opportunity to vote upon the question, "Is it expedient that municipal suffrage be granted to women?" with the following results:—

	Yes.	No.
Male voters	87,000	186,976
Female ,,	22,204	861

Since 1880, with the exception of 1883, and of 1891-94, Massachusetts has annually elected a Republican governor, and the majority of the Republican party in both branches of the legislature has usually been very large. The division in the Democratic party, due to its declaration in favour of the free coinage of silver at the ratio to gold of 16 to 1, has tended to increase the Republican preponderance.

Liquor Laws.—In 1881 a local option law was passed, providing for the granting of licences for the sale of liquor only in cities and towns voting at the annual election to authorize their issue. In 1888 the number of licences which may be granted in municipalities voting in favour of their issue was limited to one for each 1000 inhabitants, except in Boston, where one licence may be issued for every 500 inhabitants. The vote varies from year to year, and it is not unusual for a certain number of municipalities to change from "licence" to "no licence," and *vice versa*. The general result has been that centres of population, especially where the foreign element is large, usually vote "Yes," while those in which native population predominates, as well as the smaller towns, usually vote "No." Through a growing acquiescence in the operation of the local option law, the relative importance of the vote of the Prohibition party has of late years diminished.

Patents and Post.—The number of patents for inventions issued was in 1898 one to every 1428 persons in the population, this ratio being exceeded in Connecticut only. The total postal receipts for 1898 were \$5,759,154, an amount exceeded in Illinois, New York, and Pennsylvania only.

Finances.—The aggregate valuation made by local assessors of property, real and personal, was, in 1899, \$2,876,021,222. Certain descriptions of personal property—of which the largest items are the taxable excess of the valuation of corporations over their visible and tangible property which is locally taxed, and the taxable savings banks deposits—are not subject to valuation by municipal assessors, but are made to contribute to the revenues of the commonwealth. If these descriptions of property are included, the valuation in 1899 was: real estate, \$2,247,094,547; personal property, \$1,515,605,757; total, \$3,762,700,304. The total valuation of the capital stock of corporations in 1899 was \$707,183,138, an increase of \$81,588,118 over that of 1898. The aggregate net state debt, *i.e.*, after deduction of the several sinking funds, has increased rapidly from \$6,140,380 in 1896 to \$16,869,171 in 1900. This increase has been chiefly due to the erection of important public buildings, to the construction of state highways and metropolitan park roadways, to the improvement of Boston harbour, to the abolition of grade crossings of railways, and to the expenses incurred in the Spanish war of 1898. The aggregate net debt of the municipalities was, in 1899, \$128,051,487, or 4 $\frac{1}{10}$ per cent. of the local valuation, a proportion greater than that in any other year subsequent to 1870, when it was the same.

Banks.—The increase in savings banks deposits in 1899 over those of the previous year was \$29,559,124, the greatest gain in any year since 1834, when reports were first required by law. In 1895 the average deposit to each account was \$337, and to each person of the population, \$175; both of these proportions are steadily mounting, and furnish an accurate test of the general prosperity and thrift. In 1899, when the deposits aggregated \$518,202,048, there were 1,477,447 accounts, with an average of \$350 to each. The number of national banks in operation in Massachusetts on 31st October 1899 was 250, a number exceeded only in New York, Pennsylvania, and Ohio. The paid-up capital of these banks was \$80,827,500, second only to the amount so invested in New York. There are 36 trust companies transacting business, with deposits of \$129,652,632 and total assets of \$156,337,419.

Railways.—The total length of railway lines within the commonwealth in 1899 was 2107. The total length of main track of street railways worked by electricity was 1537, and is increasing

rapidly. The aggregate capital stock of the 46 railway corporations, 30th June 1899, was \$213,255,282. The aggregate capital stock of the 116 street railway companies, 30th September 1899, \$41,380,143.

Commerce.—In the magnitude of its foreign commerce Boston is the second port in the United States, being surpassed only by New York. For the year ending 30th June 1900, the total value of exports was \$143,708,232, or nearly one-tenth of the total exports of the United States. The total value of imports for the same period was \$61,452,370.

Manufactures.—In 1900 Massachusetts ranked third among the states of the Union in the amount of capital invested in manufactures and in the number of hands employed, and fourth in the value of manufacturing products. In the textile industry Massachusetts continues to be the foremost state in the Union. In 1900 its textile products exceeded those of Pennsylvania, the state ranking next to it, by 35·2 per cent. The growth of manufactures during the decade 1890-1900 is shown by the following general statistics:—

	1890.	1900.	Per cent. of Increase.
Number of establishments	26,923	29,180	8·4
Capital	\$630,032,341	\$823,264,287	30·7
Salaried officials, clerks, &c.	37,912 ¹	27,860	26·5 ²
Salaries	33,826,172 ¹	\$31,257,630	7·6 ²
Wage-earners	447,270	497,448	11·2
Total wages	\$205,844,337	\$228,240,442	10·9
Miscellaneous expenses	\$63,083,782	\$73,209,015	16·1
Cost of materials used	\$473,199,434	\$552,717,955	16·8
Value of products	\$888,160,403	\$1,035,198,989	16·6

The following table shows the statistics of the principal manufacturing industries, with the number of establishments, capital, average number of wage-earners (exclusive of salaried officials, clerks, &c.), and the value of products:—

Industries.	Number of Establishments.	Capital.	Wage-earners.	Value of Products.
Boot and shoe cut stock	270	\$5,476,277	4,390	\$13,238,922
Boots and shoes, factory product	640	87,577,680	58,645	117,115,248
Boots and shoes, rubber	6	13,157,321	5,250	16,490,015
Carriages and waggons	888	5,594,939	3,164	6,118,121
Clothing, men's	194	3,738,174	3,393	9,830,954
" women's	119	1,616,991	3,443	5,201,650
Confectionery	249	2,212,359	2,942	7,014,532
Cordage and twine	19	7,687,434	3,308	9,635,571
Electrical apparatus and supplies	54	8,259,612	5,202	10,490,361
Foundry and machine-shop products	825	62,498,989	32,234	56,290,159
Furniture, factory product	120	10,957,220	6,092	11,244,508
Iron and steel	8	13,738,593	6,125	18,491,159
Jewellery	188	4,917,105	5,696	10,315,334
Leather—tanned, curried, and finished	119	15,317,940	7,010	26,067,714
Liquors, malt	40	18,186,623	1,651	11,255,618
Lumber	696 ²	10,378,208	5,202	12,818,511
Paper and wood pulp	93	26,692,922	9,001	22,741,461
Printing and publishing	981	19,325,956	10,850	25,964,650
Rubber and elastic goods	70	11,518,650	5,944	18,855,059
Slaughtering and meat-packing, wholesale	11	9,016,672	2,337	27,505,698
Sugar and molasses, refining	7	13,974,045	592	19,626,882
Textiles	512	274,332,129	149,346	214,600,980

The textile industries employed 30 per cent. of the wage-earners engaged in manufactures, and the products were valued at 20·7 per cent. of the total value of the products. Of these industries the most important subdivisions, with the value of their products, are the following: carpets and rugs, \$6,966,237; cotton goods, including cotton smallwares, \$111,125,175; dyeing and finishing textiles, \$8,868,290; hosiery and knitted goods, \$6,620,257; silk and silk goods, \$5,957,532; woollen goods, \$30,888,104; and worsted goods, \$40,557,363.

Agriculture, &c.—In 1900 there were 37,715 farms, containing 3,147,064 acres, of which 41·1 per cent. was improved land. The total value of farm property was \$182,646,704, and was made up as follows: land, improvements, and buildings, \$158,019,290; implements and machinery, \$8,828,950; live stock, \$15,798,464. During the preceding year the expenditure for labour was \$7,487,280; and for fertilizers, \$1,320,600. Of the total number of farms 90·4 per cent. were worked by the owners, 8·3 per cent. by cash tenants,

¹Includes proprietors and firm members, with their salaries.

²Decrease.

and 1·3 per cent. by share tenants. The total value of farm products in 1899 was \$42,298,274; the acreages, quantities, and values of the principal crops are shown by the following table:—

Products.	Aeres.	Quantity.	Value.
Indian corn . . .	39,131	1,539,980 bushels	\$771,277
Hay and forage . . .	610,023	856,505 tons	9,056,854
Tobacco	3,827	6,406,570 lb	956,399
Potatoes	27,521	3,346,590 bushels	1,800,937
Small fruits	8,346	...	1,493,714
Orchard fruits	57,268	3,158,781 bushels	1,170,868
Forest products	1,944,714
Flowers and plants	584	...	1,639,760

The most important orchard fruit was apples; in 1900 the number of trees was 1,852,046, which yielded the preceding year 3,023,436 bushels of fruit. The number and value of farm animals in 1900 were as follows:—184,562 dairy cows, \$6,546,951; 101,382 other neat cattle, \$1,583,963; 75,034 horses, \$5,826,457; 33,869 sheep (not including lambs), \$142,076; 78,925 swine, \$549,617.

The amount of capital invested in the fishing industry in 1895 was \$5,338,828, and the value of the products \$5,703,143.

Education.—The aggregate sum raised by taxation and expended upon the public schools was, in 1899, \$13,624,814, or an average amount for each child in the average membership of the public schools of \$34. The ratio of pupils in high schools to the whole number in all the schools is 8½ per cent., and is increasing. The ratio of private school pupils to all the pupils in the state is less than 1 to 7. Fifty cities and towns maintain free evening schools. The proportion of women employed as teachers in the public schools to that of men so employed is about 10 to 1. The average pay of male teachers per month is \$136, of female teachers \$51. The average number of months (20 school days each) during which the public schools are kept open is 9½. The commonwealth maintains ten normal schools. In 1894 manual training was made a part of the school system of all municipalities having 20,000 inhabitants. By a recent law, cities in which there are in operation 450,000 spindles may maintain textile schools, the commonwealth contributing, up to \$25,000, a sum equal to the amount appropriated for the purpose by such city or paid by individuals. Two such schools in Lowell and New Bedford are already in successful operation. The commonwealth maintains on board the U.S.S. *Enterprise* a nautical training-school for instruction in the science and practice of navigation. The regular course is two years, and the average number of pupils is rather over 100. During the Spanish war more than 50 per cent. of the graduates and cadets of this school enlisted in the United States service. Of the 353 cities and towns only five, representing less than one-half of 1 per cent. of the population, are without free library privileges, and in three of these there are association libraries which charge a small fee. The Boston Public Library is the largest free municipal library in the world, and the Harvard University Library is exceeded in the United States only by this and by the Congressional Library at Washington. Of the adult male population of the state in 1900, 6·4 per cent. were illiterate (unable both to read and write). Of the 53,694 persons in this class, 48,615 were foreign-born.

Charitable Institutions.—The Massachusetts reformatory for men at Concord was opened in December 1884; the reformatory prison for women at Sherborn in October 1877. In both the reformation of the inmates is the principal purpose of the discipline and instruction, rather than mere punishment or detention. In 1892 the Massachusetts hospital for dipsomaniacs and inebriates was established, to which justices are authorized to commit patients for a period of two years. The average number of inmates is about 175. In 1898 a separate hospital for epileptics was opened, and in the same year, in the central portion of the state and at an elevation of 1200 feet, the Massachusetts hospital for consumptives and tuberculous patients, the first public hospital for tuberculous patients in the United States. It receives about 200 patients in such stages of the disease as admit of arrest or cure, the chief feature of the treatment, both in summer and winter, being what is known as hyperæration.

Public Enterprises.—During recent years the commonwealth has undertaken certain noteworthy enterprises, as the agent of the several municipalities in the immediate vicinity of Boston constituting what is known as the Metropolitan District. The greatest single enterprise ever undertaken by the commonwealth is the bringing to this metropolitan district of the water of the Nashua river from Clinton, at a distance of 40 miles from Boston. The original estimate of the cost of this work was \$27,000,000. In 1898 the daily average quantity of water consumed by each inhabitant in the district was 103 gallons. The commonwealth joined the city of Boston in the construction of a subway beneath the most congested portion of the city for the passage of electric

cars. For the better accommodation of the increasing commerce of the port of Boston, the commonwealth has bought a considerable frontage upon the harbour lines, has begun the construction of a dock capable of receiving the largest vessels, and has supplemented the work of the United States Government in deepening the approaches to the wharves. It has secured as public reservations the summit and sides of Greylock (almost 3500 feet high) in the north-western corner of the state, and of Wachusett (2018 feet) near the centre. Since 1885 a large expenditure has been incurred in the abolition of grade crossings of railways and highways, which the increasing density of the population rendered a grave danger. The usual allotment of the cost of this work is as follows:—65 per cent. is paid by the railway company, 25 per cent. by the commonwealth, and 10 per cent. by the municipality in which the crossing is located. Since 1894, when the work was begun, the commonwealth has spent \$3,000,000 in the construction and maintenance of state highways, the cost being apportioned between the commonwealth and the country in the proportion of 3 to 1.

The attempt to exterminate the Gipsy Moth, *Ocneria* (or more properly *Porthetria*) *dispar*, has attracted much attention. This notorious pest was introduced into Massachusetts in 1869 by a French naturalist, who was conducting experiments with various silk-producing insects with a view to the commercial value of the cocoon. Being allowed to escape, the Gipsy Moth multiplied until its increasing depredations were deemed too serious to be dealt with by individuals or even by towns, and in 1890 the commonwealth entered upon the task of extermination. Since then a large force of men has been annually employed in the work, and an aggregate of \$1,155,000 expended; but though the area infested has been restricted, extermination has not yet been accomplished.

Legislation.—In 1885, owing to certain local conditions, the legislature placed the administration of the police department of Boston, including the granting of liquor licences, in the hands of a board of three commissioners appointed by the governor; and in 1894 a similar board was created for Fall River. In each case the result has been an improvement in administration; but it is generally conceded that only exceptional conditions can justify this interference on the part of the state with the duty and right of local self-government, and two subsequent measures establishing such boards in other cities were defeated by executive veto. State boards of registration in pharmacy, in dentistry, and in medicine have been established, to determine and certify the qualifications of applicants. Since 1886 a state board of arbitration and conciliation has existed for the peaceful settlement of controversies between employers and employed. An Act was passed in 1895 providing for the imposition of indeterminate sentences on all convicts sentenced to the state prison otherwise than for life or as habitual criminals. Under this Act a maximum and a minimum term are established, and upon the expiration of the latter a revocable permit to be at liberty may be issued. The Habitual Criminals Act provided that a person convicted of a felony, who has previously served two sentences of not less than three years each, shall be deemed a habitual criminal, and shall be punished by imprisonment for twenty-five years. In 1898 electrocution was substituted for hanging in all cases where the death penalty is imposed. For the purpose of preventing the products of prison labour from entering into injurious competition with the products of free labour, legislation of increasing stringency has limited the number of prisoners who may be employed in specific industries. The employment of prisoners is no longer determined by its financial result. Clothing for use in the different institutions of the state is made in the prisons from cloth woven on hand-looms, and other processes are performed without the use of machinery. Authority has been given by the legislature for the purchase of waste land, not exceeding 1000 acres, for the purpose of reclaiming it by the labour of prisoners from the gaols and houses of correction. The so-called Torrens or Australian system for the registration of land titles has been adopted, and a court created for its administration. The hours of labour of women and children in mills and factories have been limited by legislation, and in 1899 eight hours were made to constitute a day's work for all labourers, workmen, and mechanics employed by or on behalf of any city or town adopting the Act at an annual election. Acts have been passed extending the common-law liability of employers, prohibiting the manufacture and sale of clothing made in unhealthy places (known as sweating-shops), and authorizing cities and towns to provide free lectures and to maintain public baths, gymnasia, and playgrounds. The referendum has been sparingly used in matters of local concern. In the case of all quasi-public corporations, rigid laws have been enacted prohibiting the issue of stock or bonds unless the par value is first paid in, prohibiting the declaration of any stock or scrip dividend, and requiring that new stock shall be offered to stockholders at not less than its market value, to be determined by the proper state officials, any shares not so subscribed for to be sold at public auction. These laws are aimed at preventing fictitious

capitalization and "stock-watering." What is known as civil service reform legislation was first applied to the public service of Massachusetts in 1884. By subsequent legislation it has been provided that veterans of the War of the Rebellion passing the required examination shall be appointed in preference to a person not a veteran, and that the appointing power may, in its discretion, appoint a veteran without examination.

The Spanish War.—The formal declaration of war with Spain, adopted by Congress 25th April 1898, was made to date from the 21st. On the very day after war was thus formally declared the First Regiment Heavy Artillery, M.V.M., fully armed and equipped, was sent to Fort Warren in Boston harbour, then almost wholly unprotected by national troops, upon which it was thought, for a brief time, that a hostile attack might be made. In response to the calls of the President, Massachusetts contributed to the national service the regiment above named, five infantry regiments, and nearly its entire naval brigade, which saw active service in the blockading squadron and in coast defence duty. The total number furnished by Massachusetts to the national Government was 11,780. The quota assigned in the President's calls was 7388. The several militia regiments entered the U.S. service with such equipment in arms, clothing, tentage, and commissary and surgical supplies as placed them among the most thoroughly-equipped regiments furnished by any state during this brief war. Two of the infantry regiments, the 2nd and 9th, were a part of the force engaged in the reduction of Santiago, and suffered severely through disease and hardship. The 6th regiment took part in the peaceful occupation of Porto Rico. The other two infantry regiments were stationed at camps in the southern states, but the early close of the war prevented their being ordered out of the country. A most important work in furnishing supplies and medical stores to regiments in camp and to soldiers in hospital was performed by the Massachusetts Volunteer Aid Association. This association also equipped a hospital ship—purchased by the commonwealth—with every appliance which could minister to the comfort and recovery of those committed to its care. In addition to the amount allowed by the U.S. Government, the commonwealth provided for the payment of \$7 per month to every non-commissioned officer, soldier, or marine entering the service of the United States as a part of the quota of the commonwealth. (R. Wo.)

Massage.—The word *massage* has of late years come into general use to signify the method of treating disease or other physical conditions by manipulating the muscles and joints. According to Littré, the word is derived from the Arabic *mass*, and has the specific meaning of "pressing the muscular parts of the body with the hands, and exercising traction on the joints in order to give suppleness and stimulate vitality." It was probably adopted from the Arabian physicians by the French, who have played a leading part in reviving this method of treatment, which has been practised from time immemorial, and by the most primitive people, but has from time to time fallen into disuse among Western nations. In the *Odyssey* the women are returned as rattle and kneading the heroes on their return from battle. In India, under the name "shampoo" (*tshampud*), the same process has formed part of the native system of medicine from the most remote times; professional massers were employed there by Alexander the Great in 327 B.C. In China the method is also of great antiquity, and practised by a professional class; the Swedish gymnastic system instituted by Ling is derived from the book of Cong-Fou, the bonze of Tao-Sse. Hippocrates describes and enjoins the use of manipulation, especially in cases of stiff joints, and he was followed by other Greek physicians. Oribasius gives an account of the application of friction with the bare hands, which exactly corresponds with the modern practice of massage. It is worthy of note that the treatment, after being held in high esteem by the leading Greek physicians, fell into disrepute with the profession, apparently on account of its association with vicious abuses. The same drawback has made itself felt in the present day, and can only be met by the most scrupulous care in the choice of agents and the manner of their employment. Among the Greeks, Romans, Egyptians, and, later, the Turks, massage came to be part of the ordinary procedure of the bath without

any special therapeutic intention, and the usage has survived until to-day; but that mode of application was no doubt a refinement of civilized life. Medical rubbing is older and more elementary than bathing, as we see from its employment by savages. Probably it was evolved independently among different races from the natural instinct—shared by the lower animals—which teaches to rub, press, or lick any part of the body in which uneasiness is felt, and is therefore the oldest of all therapeutic means. Its systematic use among savages, not only for the removal of fatigue, but also for the treatment of disease, is sufficiently attested by Captain Cook's experience with the Pacific islanders. The interesting account of his treatment by the natives of Tahiti, for an attack of sciatica, is worth quoting:—

The manner in which our commander was freed from a rheumatic complaint, that consisted of a pain extending from the hip to the foot, deserves to be recorded. Otoo's mother, his three sisters, and eight other women went on board for the express purpose of undertaking the cure of his disorder. He accepted of their friendly offer, had a bed spread for them on the cabin floor, and submitted himself to their directions. Being desired to lay himself down amongst them, then, as many of them as could get round him, began to squeeze him with both hands, from head to foot, but more particularly in the part where the pain was lodged, till they made his bones crack, and his flesh became a perfect mummy. After undergoing this discipline about a quarter of an hour, he was glad to be released from the women. The operation, however, gave him immediate relief; so that he was encouraged to submit to another rubbing down before he went to bed; the consequence of which was that he was tolerably easy all the succeeding night. His female physicians repeated their prescription the next morning and again in the evening; after which his pains were entirely removed and the cure was perfected. This operation, which is called *romee*, is universally practised among these islanders, being sometimes performed by the men, but more generally by the women.—*Third Voyage.*

According to Weiss, the therapeutic use of massage was revived in Europe by Fabricius ab Aquapendente, who applied it to stiff joints and similar conditions. Paracelsus, in his *De Medicina Aegyptiorum* (1591), gives a description of methodical massage as practised by the Egyptians quite on modern lines. Thereafter it appears to have been adopted here and there by individual practitioners, and various references are made to it, especially by French writers. The word "massage" occurs in an essay written by Piorry for a large encyclopædia which appeared in 1818, but it was probably used before. The practice was gradually advocated by an increasing number of medical men. In Great Britain it was called "medical rubbing," and at Edinburgh Beveridge had a staff of eight trained male rubbers. A book published by Estradère in 1863 attracted much attention, but the man who contributed most to the modern popularity of massage was Metzger of Amsterdam, who began to use it tentatively in 1853, and then proceeded to study and apply it methodically. He published an essay on the subject in 1868. The modern refinements of the treatment are chiefly due to him. At the same time, its application by Weir Mitchell to hysterical and other nervous conditions, in conjunction with the "rest cure," has done much to make it known.

Massage, as now practised, includes several processes, some of which are passive and others active. The former are carried out by an operator, and consist of rubbing and kneading the skin and deeper tissues with the hands, and exercising the joints by bending the patient's limbs. The active movements consist of a special form of gymnastics, designed to exercise particular muscles or groups of muscles. In what is called "Swedish massage" the operator moves the limbs while the patient resists, thus bringing the opposing muscles into play. Some writers insist on confining the word "massage" to the rubbing processes,

and use the general term "manipulation" to cover all the movements mentioned; but this is a verbal subtlety of no importance. It is evident that alike among the Greeks, the Orientals, and savage races, the two processes have always been applied as part of the same treatment, and the definition quoted above from Littré goes to show that the word "massage" is properly applied to both.

Rubbing has been subdivided into several processes, namely, (1) stroking, (2) kneading, (3) rubbing, and (4) tapping, and some practitioners attach great importance to the application of a particular process in a particular way. As a rule, oils and other lubricants are not used. But, however it may be applied, the treatment acts essentially by increasing circulation and improving nutrition. It has been shown by Lauder Brunton that more blood actually flows through the tissues during and after rubbing. The number of red corpuscles, and, to some extent, their hæmoglobin value, are also said to be increased (Mitchell). At the same time the movement of the lymph stream is accelerated. In order to assist the flow of blood and lymph, stroking is applied centripetally, that is to say, upwards along the limbs and the lower part of the body, downwards from the head. The effects of the increased physiological activity set up are numerous. Functional ability is restored to exhausted muscles by the removal of fatigue products and the induction of a fresh blood supply; congestion is relieved; collections of serous fluid are dispersed; secretion and excretion are stimulated; local and general nutrition are improved. These effects indicate the conditions in which massage may be usefully applied. Such are various forms of paralysis and muscular wasting, chronic and subacute affections of the joints, muscular rheumatism, sciatica and other neuralgias, local congestions, sprains, contractions, insomnia and some forms of headache, in which downward stroking from the head relieves cerebral congestion. It has also been used in anæmia, hysteria and "neurasthenia," disorders of the female organs, melancholia and other forms of insanity, morphinism, obesity, constipation, inflammatory and other affections of the eye, including even cataract. General massage is sometimes applied, as a form of passive exercise, to indolent persons whose tissues are overloaded with the products of incomplete metabolism.

As with other methods of treatment, there has been a tendency on the part of some practitioners to exalt it into a cure-all, and of others to ignore it altogether. Of its therapeutic value, when judiciously used, there is no doubt, but it is for the physician or surgeon to say when and how it should be applied. He will be guided by the condition of the patient, and the effect he desires to produce in directing the employment of light and superficial friction, or deep and firm pressure, locally or generally, for a short or a long time, at long or short intervals. Affections to which it is not applicable are fevers, pregnancy, collections of pus, acute inflammation of the joints, inflamed veins, fragile arteries, wounds of the skin, and, generally speaking, those conditions in which it is not desirable to increase the circulation, or in which the patient cannot bear handling. In such conditions it may have a very injurious and even dangerous effect, and therefore should not be used in a haphazard manner without competent advice.

The revival of massage in Europe and America has called into existence a considerable number of professional operators, both male and female, who may be regarded as forming a branch of the nursing profession. Some of these are trained in hospitals or other institutions, some by private practitioners, and some not at all. Similarly, some are attached to organized societies or institutions, while others pursue their calling independently. Without going so far as to make massaging a closed profession, it is obviously desirable to have some guarantee of competency. Several things are required for a good operator. One is physical strength. Deep massage is very laborious work, and cannot be carried on for an hour, or even half an hour, without unusual muscular power. Feeble persons cannot practise it effectively at all. The duration of a sitting may vary from five or ten minutes to an hour. For general massage at least half an hour is required. The Tahitian women completed a heroic operation on Captain Cook in a quarter of an hour, but there were twelve of them, and no doubt they took turns. A single masser should have strength enough to do the work without too obvious exhaustion, which gives the patient an unpleasant impression. A second requirement is tactile and muscular sensibility. A person not endowed with a fine sense of touch and resistance is liable to exert too great or too little pressure; the one hurts the patient, the other is ineffective. Then skill and knowledge, which can only be acquired by a course of instruction, are necessary. Finally, some guarantee of cleanliness and character is almost indispensable. Independent massers may possess all these qualifications in a higher degree than those connected with an institution, but they may also be totally devoid of them, whereas connexion with a recognized hospital or society is a guarantee for a certain standard of efficiency. In London there are several such institutions, which train and send

out both male and female massers. The fee is 5s. an hour, or from two to four guineas a week. On the Continent, where trained massers are much employed by some practitioners, the fee is considerably lower; in the United States it is higher (see NURSING). For reasons mentioned above, it is most desirable that patients should be attended by operators of their own sex. If this is not insisted upon, a valuable therapeutic means will be in danger of falling into disrepute both with the medical profession and the general public.

Massa Marittima, a town and bishop's see of the province of Grosseto, Tuscany, Italy, 24 miles north-west of Grosseto. It has a cathedral, and mines of iron, mercury, lignite, and copper, with foundries, iron-works, and olive-oil mills. At Follonica, on the coast, but in this commune, are the furnaces in which are smelted the iron ore of Elba. There are also mineral springs and jets of boracic acid vapour. Population (1899), 3500.

Massawa. See ERITREA.

Massenet, Émile Frédéric Jules (1842—), one of the most individual of modern French composers, was born at Montaud, 12th May 1842. He studied at the Paris Conservatoire, where he obtained the Grand Prix de Rome in 1863 with the cantata *David Rizzio*. He has composed the following operas: *La Grande Tante*, one act, Opéra Comique, 1867; *Don César de Bazan*, three acts, Opéra Comique, 1872; *Le Roi de Lahore*, five acts, Opéra, 1877; *Hérodiade*, five acts, Brussels, 1881; *Manon*, five acts, Opéra Comique, 1884; *Le Cid*, four acts, Opéra, 1885; *Esclarmonde*, four acts, Opéra Comique, 1889; *Le Mage*, five acts, Opéra, 1891; *Werther*, four acts, Vienna, 1892; *Thaïs*, three acts, Opéra, 1894; *Le Portrait de Manon*, one act, Opéra Comique, 1894; *La Navarraise*, two acts, Covent Garden, 1894; *Sapho*, Opéra Comique, 1897; *Cendrillon*, Opéra Comique, 1900; *Grisélidis*, Opéra Comique, 1901; *Le Jongleur de Notre Dame*, Mentone, 1902. Massenet's other works include *Marie Madeleine*, sacred drama (1873); *Eve*, a mystery (1875); *La Vierge*, sacred legend (1880); six orchestral suites entitled *Scènes Hongroises*, *Scènes Pittoresques*, *Scènes Dramatiques*, *Scènes Napolitaines*, *Scènes de Féerie*, *Scènes Alsaciennes*; music to the tragedy *Les Erynnies*, to *Théodora*, *Le Crocodile*, *L'Hetman*; a requiem, *Narcisse*; an idyll, *Biblis*; a *Scène Antique*; several sets of songs, entitled *Poème d'Avril*, *Poème d'Amour*, *Poème d'Hiver*, *Poème d'Octobre*, *Poème Pastoral*, *Poème du Souvenir*; also a large number of detached songs. The foregoing list will suffice to show that Massenet is one of the most prolific composers of his time. He was professor of composition at the Conservatoire from 1878 to 1896. Among his pupils the following have already distinguished themselves: Hillemecher, Marty, Bruneau, Vidal, Pierné, Leroux, and Charpentier. Massenet undoubtedly possesses a style of his own, one which it is impossible to mistake. He is at his best in music descriptive of the tender passion, and many of the love scenes in his operas are very beautiful. Like all individual composers, he has his mannerisms, and these have not lacked imitators. His ideas with regard to operatic construction do not appear to be absolutely defined. At any rate, he has never given a strict adherence to the forms of either the old-fashioned opera or the modern lyrical drama, usually preferring to compromise between the two. *Manon* is perhaps his most popular opera.

Massey, Gerald (1828—), English poet, was born near Tring, Hertfordshire, on the 29th of May 1828. His parents were in humble circumstances, and Massey was little more than a child when he was set to hard work in a silk factory, which he afterwards deserted for the equally laborious occupation of straw-plaiting. These early years were rendered gloomy by much distress and

deprivation, against which the young man strove with increasing spirit and virility, educating himself in his spare time, and gradually cultivating his innate taste for literary work. He was attracted by the movement known as Christian Socialism, into which he threw himself with whole-hearted vigour, and so became associated with Maurice and Kingsley. His first public appearance as a writer was in connexion with a journal called *The Spirit of Freedom*, of which he became editor, and he was only twenty-two when he published his first volume of poems, *Voices of Freedom and Lyrics of Love*. These he followed in rapid succession by *The Ballad of Babe Christabel* (1854), *War Waits* (1855), *Havelock's March* (1860), and *A Tale of Eternity* (1869). Many years afterwards, in 1890, he collected the best of the contents of these volumes, with additions, into a two-volume edition of his poems called *My Lyrical Life*. He also published works dealing with spiritualism, the study of Shakespeare's sonnets, and theological speculation. It is generally understood that he was the original of George Eliot's Felix Holt. Massey's poetry has a certain rough and vigorous element of sincerity and strength which easily accounts for its popularity at the time of its production. He treated the theme of Sir Richard Grenville before Tennyson thought of using it, and handled it with much force and vitality. Indeed, Tennyson's own praise of Massey's work is still its best eulogy, for the Laureate found in him "a poet of fine lyrical impulse, and of a rich half-Oriental imagination." The inspiration of his poetry is essentially British; he was a patriot to the core. Crudities of expression and melody are only to be expected in a talent reared among such unpoetic surroundings; but even where, as Tennyson said, he makes the "good old English tongue crack and sweat," the inequality of tone is really due to a superabundance of force, irresistible and infectious, if not always under control. He has the true lyric ring, the note of natural and spontaneous melody, and his virile and buoyant verse deserves a more emphatic recognition than it would seem to have received at the hands of a younger generation.

Massillon, a city of Stark county, Ohio, U.S.A., situated on the Tuscarawas river, north-east of the centre of the state, at an altitude of 952 feet. It is on the Ohio canal, and on the Cleveland, Lorain and Wheeling, the Pennsylvania, and the Wheeling and Lake Erie railways. It is in a farming, coal, and building-stone region, and has large manufactories, including iron and steel works, agricultural implement works, paper-mills and glass-works. Population (1890), 10,092; (1900), 11,944, of whom 1693 were foreign-born and 83 were negroes.

Masson, David (1822—), Scottish man of letters, was born at Aberdeen, 2nd December 1822, and educated at Marischal College. Intending to enter the Church, he proceeded to Edinburgh University, where he studied theology under Dr Chalmers, whose friendship he enjoyed until the divine's death in 1847. However, abandoning his project of the ministry, he returned to his native city to undertake the editorship of *The Banner*, a weekly paper devoted to the advocacy of Free Kirk principles. After two years he resigned this post and went back to the capital, bent upon pursuing a purely literary career. There he wrote a great deal for the firm of Messrs W. and R. Chambers, several of the volumes of their well-known "Educational Course" being Masson's work, besides contributing to *Fraser's Magazine*, *Dublin University Magazine* (in which appeared his essays on Chatterton), and other periodicals. In 1847 he came to London, where he found wider scope for his untiring energy and ample knowledge. His sympathy with Liberal

principles was manifested by his accepting the secretaryship of the "Friends of Italy," a society which did much to promote Italian liberty, one of its leading members being Mr Stansfeld. In 1852 he was appointed professor of English literature at University College, London, in succession to A. H. Clough, and from 1858 to 1865 he edited *Macmillan's Magazine*. In 1865 he was selected for the chair of English literature at Edinburgh, and this post he retained till 1895. In 1879 he became editor of the Register of the Scottish Privy Council, and in 1893 was appointed Historiographer Royal for Scotland. His *magnum opus* is his *Life of Milton*, in six volumes, the first of which appeared in 1858 and the last in 1880. He also edited De Quincey's *Collected Works*; and among his other publications are *Essays, Biographical and Critical* (1856, reprinted with additions, 1874), *British Novelists and their Styles* (1859), *Drummond of Hawthornden* (1873), and *Edinburgh Sketches* (1892).

Masulipatam, or BANDAR, a seaport town of British India, administrative headquarters of the Kistna district of Madras, on one of the mouths of the river Kistna, 215 miles north of Madras city. Population (1881), 35,056; (1891), 38,809; municipal income (1897-98), Rs.65,710. It is a centre of the weaving industry, and was formerly famous for printed chintzes and coloured kerchiefs. It is a station of the Church Missionary Society. The port is only a roadstead, where vessels anchor 5 miles out. In 1897-98 the total sea-borne trade of the district was valued at Rs.27,51,324. It is proposed to construct a branch line from Bezvara on the Southern Mahratta Railway. Noble College had 74 students in 1896-97, and there are two high schools, with 533 pupils. There are a club and two literary associations, and four printing-presses, issuing a district gazette and three vernacular periodicals. Memories of Mrs Draper, Sterne's "Eliza," are still cherished.

Matabeleland. See RHODESIA (SOUTH).

Matanzas, an important commercial city of Cuba and capital of Matanzas province, situated on the north coast, about 60 miles east of Havana. There are many large warehouses, rum distilleries, sugar-mills, and railway machine-shops. It is the chief outlet for an extensive sugar region to the south, the normal exports of sugar amounting to nearly \$15,000,000 per annum. It is considered the healthiest city in the island. The streets are well laid out and paved; there are several handsome ornamental plazas, and the better houses are large, commodious two-storey buildings. There are several club-houses, churches, and a large theatre. Near it are two of the most noted natural resorts of Cuba, the valley of the Yumuri, about two miles west, and the caves of Bellamar, a few miles east of the city. Railways run from Matanzas south, east, and west, making it the centre of communication. The population in 1899 was 36,374. In the Spanish-American war of 1898 Matanzas was bombarded by the United States warships, and much amusement was created in Europe by the telegraphic announcement that one mule had been injured. The Matanzas mule has become proverbial.

Mataro, a town of Spain, in the province of Barcelona, on the Mediterranean coast, and on the railway running from Barcelona to France. Its population was 19,918 in 1897. The local industries consist of manufactures of linen and cotton goods, soap, paper, cremor, chemicals, starch, glass, leather, chocolate, liqueurs and alcohols, and flour- and saw-milling. Like most of the more progressive Catalan towns, Mataro has good modern public buildings and schools.

MATHEMATICAL INSTRUMENTS.

CALCULATING MACHINES, designed for the mechanical performance of numerical calculations, have in modern times come into ever-increasing use. They may be classified as follows:—(i.) *Calculating machines.* Addition machines; the first invented by Pascal (1642). (ii.) Addition machines modified to facilitate multiplication; the first by Leibnitz (1671). (iii.) True multiplication machines; Léon Bollés (1888), Steiger (1894). (iv.) Difference machines; Müller (1786), Babbage (1822). (v.) Analytical machines; Babbage (1834). The number of distinct machines of the first three kinds is remarkable and is being constantly added to, old machines being improved and new ones invented; Professor R. Mehmke has counted over eighty distinct machines of this type. The fullest published account of the subject is given by Mehmke in the *Encyclopædie der Mathematischen Wissenschaften*, article "Numerisches Rechnen," vol. i., heft 6 (1901). It contains historical notes and full references. Dyck's *Catalogue* also contains descriptions of various machines. We will confine ourselves to explaining the principles of some leading types, without giving an exact description of any particular one.

Fig. 1.

Practically all calculating machines contain a "counting work," a series of "figure discs" consisting in the original form of horizontal circular discs (Fig. 1), on which the figures 0, 1, 2 to 9 are marked. Each disc can turn about its vertical axis, and is covered by a fixed plate with a hole or "window" in it through which one figure can be seen. On turning the disc through one-tenth of a revolution this figure will be changed into the next higher or lower. Such turning is called a "step," and this step is *positive* if the next higher and *negative* if the next lower figure appears. Each positive step therefore adds one unit to the figure under the window, while two steps add two, and so on. If a series, say six, of such figure discs be placed side by side, their windows lying in a row, then any number of six places can be made to appear, for instance 000373. In order to add 6425 to this number, the discs, counting from right to left, have to be turned 5, 2, 4, and 6 steps respectively. If this is done the sum 006798 will appear. In case the sum of the two figures at any disc is greater than 9, if for instance the last figure to be added is 8 instead of 5, the sum for this disc is 11 and the 1 only will appear. Hence an arrangement for "carrying" has to be introduced. This may be done as follows. The axis of a figure disc contains a wheel with ten teeth. Each figure disc has, besides one long tooth which when its 0 passes the window turns the next wheel to the left, one tooth forward, and hence the figure disc one step. The actual mechanism is not quite so simple, because the long teeth as described would gear also into the wheel to the right, and besides would interfere with each other. They must therefore be replaced by a somewhat more complicated arrangement, which has been done in various ways not necessary to describe more fully. On the way in which this is done, however, depends to a great extent the durability and trustworthiness of any arithmometer; in fact, it is often its weakest point. If to the series of figure discs described arrangements are added for turning each disc through a required number of steps, we have an addition machine, essentially of Pascal's type, in which each disc had to be turned by hand. Key-

boards have been introduced by Stettner (1882), Max Mayer (1887), and in the comptometer by Dorr Z. Felt of Chicago.¹ In the comptograph also by Felt and in "Bourrough's Registering Accountant" the result is printed. These machines require that for each figure of the number to be added a key be pressed down; and multiplication, as repeated addition, becomes somewhat laborious, depending for rapid execution essentially on the skill of the operator. The figure discs described may, of course, be replaced by cylindrical discs thick enough to receive the figures on the rim, and may then be mounted on one common axis, greatly to the advantage of compactness.

To adapt an addition machine, as described, to rapid multiplication the turnings of the separate figure discs are replaced by one motion, commonly the turning of a handle. As, however, the different discs have to be turned through different steps, a contrivance has to be inserted which can be "set" in such a way that each disc is moved by one turn of the handle through a number of steps equal to the number of units which is to be added on that disc; and this may be done by making each of the figure discs receive on its axis a ten-toothed wheel, called hereafter the A-wheel, which is acted on either directly or indirectly by another wheel (called the B-wheel) in which the number of teeth can be varied from 0 to 9. This variation of the teeth has been effected in different ways. Theoretically the simplest seems to be to have on the B-wheel nine teeth which can be drawn back into the body of the wheel, so that at will any number from 0 to 9 can be made to project. This idea, previously mentioned by Leibnitz, has been reinvented by Böhdner in the "Brunsviga." Another way, also due to Leibnitz, consists in inserting between the axis of the handle bar and the A-wheel a "stepped" cylinder. This may be considered as being made up of ten wheels large enough to contain about twenty teeth each; but most of these teeth are cut away so that these wheels retain in succession 9, 8, . . . 1, 0 teeth. If these are made as one piece they form a cylinder with teeth of lengths from 9, 8 . . . times the length of a tooth on a single wheel.

In the diagrammatic vertical section of such a machine (Fig. 2) FF is a figure disc with a conical wheel A on its axis. In the covering plate HK is the window W. A stepped cylinder is shown

Fig. 2.

at B. The axis Z, which runs along the whole machine, is turned by a handle, and itself turns the cylinder B by aid of conical wheels. Above this cylinder lies an axis EE with square section along which a wheel D can be moved. The same axis carries at E'

¹ For a fuller description of the manner in which a mere addition machine can be used for multiplication and division, and even for the extraction of square roots, see an article by C. V. Boys in *Nature*, 11th July 1901.

a pair of conical wheels C and C', which can also slide on the axis so that either can be made to drive the A-wheel. The covering plate MK has a slot above the axis EE allowing a rod LL' to be moved by aid of a button L, thus carrying the wheel D with it. Along the slot is a scale of numbers 0 1 2 . . . 9 corresponding with the number of teeth on the cylinder B, with which the wheel D will gear in any given position. A series of such slots is shown in the top middle part of Steiger's machine (Fig. 3). Let now the handle driving the axis Z be turned once round, the button being set to 4. Then four teeth of the B-wheel will turn D and with it the A-wheel, and consequently the figure disc will be moved four steps. These steps will be positive or forward if the wheel C gears in A, and consequently four will be added to the figure showing at the window W. But if the wheels CC' are moved to the right, C' will gear with A moving backwards, with the result that four is subtracted at the window. This motion of all the wheels C is done simultaneously by the push of a lever which appears at the top plate of the machine, its two positions being marked "addition" and "subtraction." The B-wheels are in fixed positions below the plate MK. Level with this, but separate, is the plate KH with the window. On it the figure discs are mounted. This plate is hinged at the back at H and can be lifted up, thereby throwing the A-wheels out of gear. When thus raised the figure discs can be set to any figures; at the same time it can slide to and fro so that an A-wheel can be put in gear with any C-wheel forming with it one "element." The number of these varies with the size of the machine. Suppose there are six B-wheels and twelve figure discs. Let these be all set to zero with the exception of the last four to the right, these showing 1 4 3 2, and let these be placed opposite the last B-wheels to the right. If now the buttons belonging to the latter be set to 3 2 5 6, then on turning the B-wheels all once round the latter figures will be added to the former, thus showing 4 6 8 8 at the windows. By the aid of wheels not shown in the diagram, this turning of the B-wheels is performed simultaneously by the movement of one handle. We have thus an addition machine. If it be required to multiply a number, say 725, by any number up to six figures, say 357, the buttons are set to the figures 725, the windows all showing zero. The handle is then turned, 725 appears at the windows, and successive turns add this number to the first. Hence seven turns show the product seven times 725. Now the plate with the A-wheels is lifted and moved one

step to the right and the handle is turned twice, thus adding twenty times 725 to the product obtained. Finally, by moving the plate again, and turning the handle three times, the required product is obtained. To this another product may be added. If the machine has six B-wheels and twelve discs the product of two six-figure numbers can be obtained. Division is performed by repeated subtraction. The lever regulating the C-wheel is set to subtraction, producing negative steps at the discs. The dividend is set up at the windows and the divisor at the buttons. Each turn of the handle subtracts the divisor once. To count the number of turns of the handle a second set of windows is arranged between and in front of the first, with number discs below. These have no carrying arrangement, but the one which happens to be near the handle is turned one step for each turn of the handle.

It will be seen that this arrangement is really an addition machine. The machine described is essentially that of M. Thomas of Colmar, which was the first that came into practical use. Of earlier machines these of Leibnitz, Müller (1782), and Hahn (1809) deserve to be mentioned (see Dyck, *Catalogue*). Thomas's machine has had many imitations, both in England and on the Continent, with more or less important alterations. Mr Joseph Edmondson of Halifax has given it a circular form, which has many advantages. The accuracy and durability of the machine depend to a great extent on the manner in which the carrying machine is constructed. No wheel must be capable of moving in any other way than that required; hence every part must be locked and be released only when required to move. Further, any disc must carry to the next only after the carrying to itself has been completed. If all were to carry at the same time a considerable force would be required to turn the handle, and serious strains would be introduced. It is for this reason that the B-wheels or cylinders have the greater part of the circumference free from teeth. Again, the

carrying acts generally as in the machine described, in one sense only, and this involves that the handle be turned always in the same direction. Subtraction therefore cannot be done by turning it in the opposite way, hence the two wheels C and C' are introduced. These are moved all at once by one lever acting on a bar shown at R in section (Fig. 2).

In the Brunsviga, the figure disc is replaced by a cylinder with the figures at the rim; the wheel mounted beside it is acted on directly by the B-wheel. By an ingenious contrivance the teeth are made to appear from out of the rim to any desired number. The carrying mechanism, too, is different, and so arranged that the handle can be turned either way, no special setting being required for subtraction or division. It is extremely handy, taking up much less room than the others. Professor Selling of Würzburg has invented an altogether different machine, which has been made by Max Ott, of Munich. The B-wheels are replaced by lazy-tongs. To the joints of these the ends of racks are pinned; and as they are stretched out the racks are moved forward 0 to 9 steps, according to the joints they are pinned to. The racks gear directly in the A-wheels, and the figures are placed on cylinders as in the Brunsviga. The carrying is done continuously by a train of epicycloidal wheels. The working is thus rendered very smooth, without the jerks which the ordinary carrying tooth produces; but the arrangement has the disadvantage that the resulting figures do not appear in a straight line, a figure followed by a 5, for instance, being already carried half a step forward. This is not a serious matter in the hands of a mathematician or an operator using the machine constantly, but it is serious for casual work. Anyhow, it has prevented the machine from being a commercial success, and it is not any longer made. For ease and rapidity of working it surpasses all others. Since the lazy-tongs allow of an extension equivalent to five turnings of the handle, if the multiplier is 5 or under, one push forward will do the same as five (or less) turns of the handle, and more than two pushes are never required.

The Steiger-Egli machine is a multiplication machine, of which Fig. 3 gives a picture as it appears to the manipulator. The lower part of the figure contains, under the covering plate, a carriage W with two rows of windows for the figures marked *ff* and *gg*. On pressing down the button W the carriage can be moved to right or left. Under each window is a figure-disc, as in the Thomas machine. The upper part has three sections. The one to the right

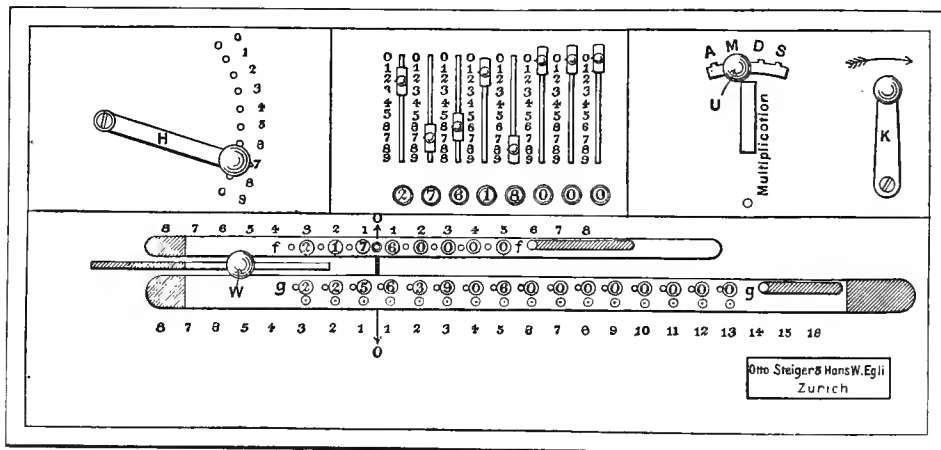

Fig. 3.

contains the handle K for working the machine, and a button U for setting the machine for addition, multiplication, division, or subtraction. In the middle section a number of parallel slits are seen, with indices which can each be set to one of the numbers 0 to 9. Below each slot, and parallel to it, lies a shaft of square section on which a toothed wheel slides to and fro with the index in the slot. Below these wheels again lie 9 toothed racks. By setting the index in any slot the wheel below it comes into gear with one of these racks. On moving the rack, the wheels turn their shafts and, as in the Thomas machine, the figure-discs *gg* opposite to them. The dimensions are such that a motion of a rack through 1 cm. turns the figure-disc through one "step" or adds 1 to the figure under the window. The racks are moved by an arrangement contained in the section to the left of the slits. There is a vertical plate called the multiplication table block, or more shortly, the *block*. From it project rows of horizontal rods of lengths varying from 0 to 9 centimetres. If one of these rows is brought opposite the row of racks and then pushed forward to the right through 9 cm., each rack will move and add to its figure-disc a number of units equal to the number of centimetres of the rod which operates on it. The block has a square

face divided into a hundred squares. Looking at its face from the right—i.e., from the side where the racks lie—suppose the horizontal rows of these squares numbered from 0 to 9, beginning at the top, and the columns numbered similarly, the 0 being to the right; then the multiplication table for numbers 0 to 9 can be placed on these squares. The row 7 will therefore contain the numbers 63, 56, . . . 7, 0. Instead of these numbers, each square receives two “rods” perpendicular to the plate, which may be called the units-rod and the tens-rod. Instead of the number 63 we have thus a tens-rod 6 cm. and a units-rod 3 cm. long. By aid of a lever H the block can be raised or lowered so that any row of the block comes to the level of the racks, the units-rods being opposite the ends of the racks.

The action of the machine will be understood by considering an example. Let it be required to form the product 7 times 385. The indices of three consecutive slots are set to the numbers 3, 8, 5 respectively. Let the windows *gg* opposite these slots be called *a*, *b*, *c*. Then to the figures shown at these windows we have to add 21, 56, 35 respectively. This is the same thing as adding first the number 165, formed by the units of each place, and next 2530 corresponding to the tens; or again, as adding first 165, and then moving the carriage one step to the right, and adding 253. The first is done by moving the block with the units-rods opposite the racks forward. The racks are then put out of gear, and together with the block brought back to their normal position; the block is moved sideways to bring the tens-rods opposite the racks, and again moved forward, adding the tens, the carriage having also been moved forward as required. This complicated movement, together with the necessary carrying, is actually performed by one turn of the handle. During the first quarter-turn the block moves forward, the units-rods coming into operation. During the second quarter-turn the carriage is put out of gear, and moved one step to the right while the necessary carrying is performed; at the same time the block and the racks are moved back, and the block is shifted so as to bring the tens-rods opposite the racks. During the next two quarter-turns the process is repeated, the block ultimately returning to its original position. Multiplication by a number with more places is performed as in the Thomas. The advantage of this machine over the Thomas in saving time is obvious. Multiplying by 817 requires in the Thomas 16 turns of the handle, but in the Steiger-Egli only 3 turns, with 3 settings of the lever H. If the lever H is set to 1 we have a simple addition machine like the Thomas or the Brunsviga. The inventors state that the product of two 8-figure numbers can be got in 6-7 seconds, the quotient of a 6-figure number by one of 3 figures in the same time, while the square root to 5 places of a 9-figure number requires 18 seconds.

Machines of far greater powers than the arithmometers mentioned have been invented by Babbage and by Scheutz. An account of these is given in the article CALCULATING MACHINES (*Ency. Brit.* vol. iv.), but without any description of the mechanism; in fact, such description is impossible without elaborate drawings. Of Babbage's *Difference Machine*, however, the following account will afford some idea of its working. Imagine a number of striking clocks placed in a row, each with only an hour hand, and with only the striking apparatus retained. As the hand comes opposite a number on the

dial of the first clock, it strikes that number of times. Let this clock be connected with the second in such a manner that by each stroke of the first the hand of the second is moved from one number to the next, but can only strike when the first comes to rest. If the second hand stands at 5 and the first strikes 3, then when this is done the second will strike 8; the second will act similarly on the third, and so on. Let there be four such clocks with hands set to the numbers 6, 6, 1, 0, respectively. Now set the third clock striking 1, this sets the hand of the fourth clock to 1; strike the second (6), this puts the third to 7 and the fourth to 8. Next strike the first (6); this moves the other hands to 12, 19, 27, respectively, and now repeat the striking of the first. The hand of the fourth clock will then give in succession the numbers 1, 8, 27, 64, &c., being the cubes of the natural numbers. The numbers thus obtained on the last dial will have the differences given by those shown in succession on the dial before it, their differences by the next, and so on till we come to the constant difference on the first dial. A function

$$y = a + bx + cx^2 + dx^3 + ex^4$$

gives, on increasing *x* always by unity, a set of values for which the fourth difference is constant. We can, by an arrangement like the above, with five clocks calculate *y* for *x*=1, 2, 3, . . . to any extent. This is the principle of Babbage's difference machine. The clock dials have to be replaced by a series of dials as in the arithmometers described, and an arrangement has to be made to drive the whole by turning one handle by hand or some other power. Imagine further that with the last clock is connected a kind of typewriter which prints the number, or, better, impresses the number in a soft substance from which a stereotype casting can be taken, and we have a machine which, when once set for a given formula like the above, will automatically print, or prepare stereotype plates for the printing of, tables of the function without any copying or typesetting, thus excluding all possibility of errors.

With regard to Babbage's *Analytical Machine*, the statement in the article referred to, that Babbage left complete plans, is incorrect. The committee of the British Association appointed to consider the possibility of having it made came to the conclusion (*Brit. Assoc. Report*, 1878, pp. 92-102) that no detailed working drawings existed at all, but that the drawings were only diagrammatic and not nearly sufficient to put into the hands of a draughtsman for making working plans; and “that in the present state of the design it is not more than a theoretical possibility.” A full account of all the work done by Babbage in connexion with calculating machines, and much else published by others in connexion therewith, is contained in a work published by his son, General Babbage.

Slide rules are instruments for performing logarithmic calculations mechanically, and are extensively used, especially where only rough approximations are required. They are almost as old as logarithms themselves. Edmund Gunter, the colleague of Briggs at Gresham College, drew a “logarithmic line” on his “Scales” as follows (Fig. 4):—On a line AB lengths are set off to scale to represent the common logarithms of the

Slide rules.

Fig. 4.

numbers 1 2 3 . . . 10, and the points thus obtained are marked with these numbers. As $\lg 1 = 0$, the beginning A has the number 1 and B the number 10, hence the unit of length is AB as $\lg 10 = 1$. The same division is repeated from B to C. The distance 1,2 thus represents $\lg 2$, 1,3 gives $\lg 3$, the distance between 4 and 5 gives $\lg 5 - \lg 4 = \lg \frac{5}{4}$, and so for others. In order to multiply two numbers, say 2 and 3, we have $\lg 2 \times 3 = \lg 2 + \lg 3$. Hence, setting off the distance 1,2 from 3 forward by the aid of a pair of compasses will give the distance $\lg 2 + \lg 3$, and will bring us to 6 as the required product. Again, if it is required to find $\frac{4}{5}$ of 7, set off the distance between 4 and 5 from 7 backwards, and the required number will be obtained. In the actual scales the spaces between the numbers are subdivided into 10 or even more parts, so that from two to three figures may be read. The numbers

2, 3 . . . in the interval BC give the logarithms of 10 times the same numbers in the interval AB; hence, if the 2 in the latter means 2 or .2, then the 2 in the former means 20 or 2.

Soon after Gunter's publication (1620) of these “logarithmic lines,” Wingate (1872) constructed the slide rule by repeating the logarithmic scale on a tongue or “slide,” which could be moved along the first scale, thus avoiding the use of a pair of compasses. A clear idea of this device can be formed if the scale in Fig. 4 be copied on the edge of a strip of paper placed against the line A C. If this is now moved to the right till its 1 comes opposite the 2 on the first scale, then the 3 of the second will be opposite 6 on the top scale, this being the product of 2 and 3; and in this position every number on the top scale will be twice that on the lower. For every position of

the lower scale the ratio of the numbers on the two scales which coincide will be the same. Therefore multiplications, divisions, and simple proportions can be solved at once.

Many different forms of slide rules are now on the market. The handiest for general use is the Gravet rule made by Tavernier-Gravet in Paris, according to instructions of the mathematician M. Mannheim of the Ecole Polytechnique in Paris. It contains at the back of the slide scales for the logarithms of sines and tangents so arranged that they can be worked with the scale on the front. An improved form is now made by Davis and Son of Derby, who engrave the scales on white celluloid instead of on box-wood, thus greatly facilitating the readings. These scales have the distance from one to ten about twice that in Fig. 4. Tavernier-Gravet makes them of that size and longer, even $\frac{1}{2}$ metre long. But they then become somewhat unwieldy, though they allow of reading to more figures. To get a handy long scale Professor G. Fuller has constructed a spiral slide rule drawn on a cylinder, which admits of reading to three and four figures. The handiest of all is perhaps the "Calculating Circle" by Boucher, made in form of a watch. For various purposes special adaptations of the slide rules are met with—for instance, in various exposure meters for photographic purposes. General Strachey has introduced slide rules into the Meteorological Office for performing special calculations. At some blast furnaces a slide rule is used for determining the amount of coke and flux required for any weight of ore. Near the balance a large logarithmic scale is fixed with a slide which has three indices only. A load of ore is put on the scales, and the first index of the slide is put to the number giving the weight, when the second and third point to the weights of coke and flux required.

In order to measure the length of a curve, such as the road on a map, a wheel is rolled along it. For one revolution of the wheel the path described by its point of contact is equal to the circumference of the wheel. Thus, if a cyclist counts the number of revolutions of his front wheel he can calculate the distance ridden by multiplying that number by the circumference of the wheel. An ordinary cyclometer is nothing but an arrangement for counting these revolutions, but it is graduated in such a manner that it gives at once the distance in miles. On the same principle depend a number of instruments which, under various fancy names, serve to measure the length of any curve; they are in the shape of a small meter chiefly for the use of cyclists. They all have a small wheel which is rolled along the curve to be measured, and this sets a hand in motion which gives the reading on a dial. Their accuracy is not very great, because it is difficult to place the wheel so on the paper that the point of contact lies exactly over a given point; the beginning and end of the readings are therefore badly defined. Besides, it is not easy to guide the wheel along the curve to which it should always lie tangentially. To obviate this defect more complicated curvometers or kartometers have been devised. The handiest seems to be that of Coradi. He uses two wheels; the tracing-point, halfway between them, is guided along the curve, the line joining the wheels being kept normal to the curve. This is pretty easily done by eye; a constant deviation of 8° from this direction produces an error of only 1 per cent. The sum of the two readings gives the length. E. Fleischhauer uses three, five, or more wheels arranged symmetrically round a tracer whose point is guided along the curve; the planes of the wheels all pass through the tracer, and the wheels can only turn in one direction. The sum of the readings of all the wheels gives approximately the length of the curve, the approximation increasing with the number of the wheels used. It is stated that with three wheels practically useful results can

Curvometers.

be obtained, although in this case the error, if the instrument is consistently handled so as always to produce the greatest inaccuracy, may be as much as 5 per cent.

Planimeters are instruments for the determination by mechanical means of the area of any figure. A pointer, generally called the "tracer," is guided round the boundary of the figure, and then the area is read off on the recording apparatus of the instrument. The simplest and most useful is Amsler's (Fig. 5).

Planimeters.

It consists of two bars of metal OQ and QT, which are hinged together at Q. At O is a needle-point which is driven in the drawing board, and at T is the tracer. As this is guided round the boundary of the figure a wheel W mounted on QT rolls on the paper, and the turning of this wheel measures, to some known scale, the area. We shall give the theory of this instrument fully in an elementary manner by aid of geometry. The theory of other planimeters can then be easily understood.

Fig. 5.

Consider the rod QT with the wheel W, without the arm OQ. Let it be placed with the wheel on the paper, and now moved perpendicular to itself from AC to BD (Fig. 6). The rod sweeps over, or generates, the area of the rectangle ACDB = lp where l denotes the length of the rod and p the distance AB though which it has been moved. This distance, as measured by the rolling of the wheel, which acts as a curvometer, will be called the "roll" of the wheel and be denoted w . In this case $p = w$, and the area P is given by $P = wl$. Let the circumference

Fig. 6.

of the wheel be divided into say a hundred equal parts u ; then w registers the number of u 's rolled over, and w therefore gives the number of areas lu contained in the rectangle. By suitably selecting the radius of the wheel and the length l , this area lu may be any convenient unit, say a square inch or square centimetre. By changing l this unit will be changed.

Again, suppose the rod to turn (Fig. 7) about the end Q, then T will describe an arc of a circle, and the rod will generate an area $\frac{1}{2}l^2\theta$, where θ is the angle AQB through which the rod has turned. The wheel will roll over an arc $c\theta$, where c is the distance of the wheel from Q. The "roll" is now $w = c\theta$; hence the area generated is

$$P = \frac{1}{2} \frac{l^2}{c} w,$$

Fig. 7.

and is again determined by w .

Next let the rod be moved parallel to itself, but in a direction not perpendicular to itself (Fig. 8). The wheel will now not simply roll. Consider a small motion of the rod from QT to Q'T'. This may be resolved into the motion to RR' perpendicular to the rod, whereby the rectangle Q'T'R'R is generated, and the sliding of the rod along itself from RR' to Q'T'. During this second step no area will be generated. During the first step the roll of the wheel will give QR, whilst during the second step there will be no roll at all. The roll of the wheel will therefore measure the area of the rectangle which equals the parallelogram QTT'Q'. If the whole motion of the rod be considered as made up of a very great number of small steps, each resolved as stated, it will be seen that the roll again measured the area generated as in the first case. But it has to be noticed that now the wheel does not only roll, but also

slips, over the paper. This, as will be pointed out later, may introduce an error in the reading.

Fig. 8.

We can now investigate the most general motion of the rod. We again resolve the motion into a number of small steps. Let AB be one position, CD the next after a step so small that the arcs AC or BD over which the ends have passed may be considered as straight lines. The area generated is ACDB. This motion we resolve into a step from AB to CB', parallel to AB and a turning about C from CB' to CD, steps such as have been investigated. During the first, the "roll" will be over p the altitude of the parallelogram; during the second it will be cb . Therefore

$$w = p + cb.$$

The area generated is $lp + \frac{1}{2}l^2\theta$, or, expressing p in terms of w , $lw + (\frac{1}{2}l^2 - lc)\theta$. For a finite motion we get the area equal to the sum of the areas generated during the different steps. But the wheel will continue rolling, and give the whole roll as the sum of the rolls for the successive steps. Let then w denote the whole roll (in Fig 10), and let α denote the sum of all the small turnings θ ; then the area is

Fig. 9.

$$P = lw + (\frac{1}{2}l^2 - lc)\alpha.$$

Here α is the angle which the last position of the rod makes with the first. In all applications of the planimeter the rod is brought back to its original position. Then the angle α is either zero, or it is 2π if the rod has been once turned quite round.

Fig. 10.

Hence in the first case we have

$$P = lw \quad \dots \quad (1)$$

and w gives the area as in case of a rectangle.

In the other case

$$P = lw + lC \quad \dots \quad (2)$$

where $C = (\frac{1}{2}l^2 - c)2\pi$, if the rod has once turned round. The number C will be seen to be always the same, as it depends only on the dimensions of the instrument. Hence now again the area is determined by w if C is known.

Thus it is seen that the area generated by the motion of the rod can be measured by the roll of the wheel; it remains to show how any given area can be generated by the rod. Let the rod move in any manner but return to its original position. Q and T then describe closed curves. Such motion may be called cyclical. Here the theorem holds:—If a rod QT performs a cyclical motion, then the area generated equals the difference of the areas enclosed by the paths of T and Q respectively. The truth of this proposition will be seen from a figure. In Fig. 11 the different positions of the moving rod QT have been marked, and its motion can be easily followed. It will be seen that every part of the area $TT'BB'$ will be passed over once and always by a forward motion of the rod,

Fig. 11.

whereby the wheel will increase its roll. The area $AA'QQ'$ will also be swept over once, but with a backward roll; it must therefore be counted as negative. The area between the curves is passed over twice, once with a forward and once with a backward roll; it therefore counts once positive and once negative; hence not at all. In more complicated figures it may happen that the area within one of the curves, say $TT'BB'$, is passed over several times, but then it will be passed over once more in the forward direction than in the backward one, and thus the theorem will still hold.

To use the planimeter, place the pole O on the paper outside the figure to be measured. Then the area generated by QT is that of

Fig. 12.

the figure, because the point Q moves on an arc of a circle to and fro enclosing no area. At the same time the rod comes back without making a complete rotation. We have therefore in formula (1), $\alpha = 0$, and hence

$$P = lw,$$

which is read off. But if the area is too large the pole O may be placed within the area.

The rod describes the area between the boundary of the figure and the circle with radius $r = OQ$, whilst the rod turns once completely round, making $\alpha = 2\pi$. The area measured by the wheel is by formula (2), $lw + (\frac{1}{2}l^2 - lc)2\pi$. To this the area of the circle πr^2 must be added, so that now

$$P = lw + (\frac{1}{2}l^2 - lc)2\pi + \pi r^2$$

or

$$P = lw + C,$$

where $C = (\frac{1}{2}l^2 - lc)2\pi + \pi r^2$ is a constant, as it depends on the dimensions of the instrument alone.

Fig. 13.

This constant is given with each instrument.

Amsler's planimeters are made either with a rod QT of fixed length, which gives the area therefore in terms of a fixed unit, say in square inches, or else the rod can be moved in a sleeve which the arm OQ is hinged (Fig. 13). This makes it possible to change the unit lw , which is proportional to l .

Fig. 14.

In the planimeters described the recording or integrating apparatus is a smooth wheel rolling on the paper or on some other surface. Amsler has described another recorder, viz., a wheel with a sharp edge. This will roll on the paper but not slip. Let the rod QT carry with it an arm CD perpendicular to it. Let there be mounted on it a wheel W , which can slip along and turn about it. If now QT is moved parallel to itself to $Q'T'$, then W will roll without slipping parallel to QT , and slip along CD . This amount of slipping will equal the perpendicular distance between QT and

Q'T, and therefore serve to measure the area swept over like the wheel in the machine already described. The turning of the rod will also produce slipping of the wheel, but it will be seen without difficulty that this will cancel during a cyclical motion of the rod, provided the rod does not perform a whole rotation. Messrs Hine and Robertson, New York, have constructed a planimeter on this principle, which, however, is only a slight modification of one described by Amsler in 1856. The end Q of the rod ends in a button which slides along a V-groove.

The first planimeter was made on the following principles:— A frame FF (Fig. 15) can move in the direction OX. It carries a rod T'T movable in its own length, hence the tracer T can be guided along any curve ATB.

Fig. 15.

When the rod has been pushed back to Q'Q, the tracer moves along the axis OX. As the frame is moved a cone VCC' mounted on it turns about its axis. The latter is slanting so that its top edge is horizontal and parallel to the rod; its vertex is opposite to Q'. A wheel W is mounted on the rod at T', or on an axis parallel to and rigidly connected with it. This wheel rests on the top edge of the cone. If now the tracer T, when pulled out through a distance y above Q, be moved parallel to OX through a distance dx, the frame moves through an equal distance, and the cone turns through an angle dθ proportional to dx. The wheel W rolls on the cone to an amount again proportional to dx, and also proportional to y, its distance from V. Hence the roll of the wheel is proportional to the area ydx described by the rod QT. As T is moved from A to B along the curve the roll of the wheel will therefore be proportional to the area AA'BB'. If the curve is closed, and the tracer moved round it, the roll will measure the area independent of the position of the axis OX, as will be seen by drawing a figure. The cone may with advantage be replaced by a horizontal disc, with its centre at V; this allows of y being negative. It may be noticed at once that the roll of the wheel gives at every moment the area A'ATQ. It will therefore allow of registering a set of values of $\int_a^x y dx$ for any values of x, and thus of tabulating the values of any indefinite integral. In this it differs from Amsler's planimeter. Planimeters of this type were first invented in 1814 by the Bavarian engineer Hermann, who, however, published nothing. They were re-invented by Prof. Tito Gonnella of Florence in 1824, and by the Swiss engineer Oppikofer, and improved by Ernst in Paris, the astronomer Hansen in Gotha, and others (see Henrici, *British Association Report*, 1894). But all were driven out of the field by Amsler's simpler planimeter.

Altogether different from the planimeters described is the hatchet planimeter, invented by Captain Prytz, a Dane, and made by Herr Cornelius Knudsen in Copenhagen. It consists of a single rigid piece like Fig. 16. The one end T is the tracer, the other Q has a sharp hatchet-like edge. If this is placed with QT on the paper and T is moved along any curve, Q will follow, describing a "curve of pursuit." In consequence of the sharp edge, Q can only move in the direction of T, but the whole can turn about Q. Any small step forward can therefore be considered as made up of a motion along QT, together with a turning about Q. The latter motion alone generates an area. If therefore a line OA=QT is turning about O, always keeping parallel to QT, it will sweep over an area equal to that generated by the more general motion of QT. Let now (Fig. 17) QT be placed on OA, and T be guided round the closed curve in the sense of the arrow. Q will describe a curve OSB. It may be made visible by putting a piece of "copying paper" under the hatchet. When T has returned to A the hatchet has the position BA. The line turning from OA about O

Fig. 16.

kept parallel to QT will describe the circular sector OAC, which is equal in magnitude and sense to AOB. This therefore measures the area generated by the motion of QT. To make this motion cyclical, suppose the hatchet turned about A till Q comes from B to O. Hereby the sector AOB is again described, and again in the positive sense, if it is remembered that it turns about T. The whole area now generated is therefore twice the area of this sector, or equal to OA.OB, where OB is measured along the arc. According to the theorem given p. 579, this area also equals the area of the given curve less the area OSBO. To make this area disappear, a slight modification of the motion of QT is required. Let the tracer T be moved, both from the first position OA and the last BA of the rod, along some straight line AX. Q describes curves OF and BH respectively. Now begin the motion with T at some point R on AX, and move it along this line to A, round the curve and back to R. Q will describe the curve DOSBED, if the motion is again made cyclical by turning QT with T fixed at A. If R is properly selected, the path of Q will cut itself, and parts of the area will be positive, parts negative, as marked in the figure, and may therefore be made to vanish. When this is done the area of the curve will equal twice the area of the sector RDE. It is therefore equal to the arc DE multiplied by the length QT; if the latter equals 10 inches, then 10 times the number of inches contained in the arc DE gives the number of square inches contained within the given figure. If the area is not too large, the arc DE may be replaced by the straight line DE.

Fig. 17.

To use this simple instrument as a planimeter requires the possibility of selecting the point R. The geometrical theory here given has so far failed to give any rule. In fact, every line through any point in the curve contains such a point. The analytical theory of the inventor, which is very similar to that given by Mr F. W. Hill (*Phil. Mag.* 1894), is too complicated to repeat here. The integrals expressing the area generated by QT have to be expanded in a series. By retaining only the most important terms a result is obtained which comes to this, that if the mass-centre be taken as R, then A may be any point on the curve. This is only approximate. Capt. Prytz gives the following instructions:—Take a point R as near as you can guess to the mass-centre, put the tracer T on it, the knife-edge Q outside; make a mark on the paper by pressing the knife-edge into it, guide the tracer from R along a straight line to a point A on the boundary, round the boundary, and back from A to R; lastly, make again a mark with the knife-edge, and measure the distance c between the marks, then the area is nearly cl where l=QT. A nearer approximation is obtained by repeating the operation after turning QT through 180° from the original position, and using the mean of the two values of c thus obtained. The greatest dimension of the area should not exceed $\frac{1}{2} l$, otherwise the area must be divided into parts which are determined separately. This condition being fulfilled, the instrument gives very satisfactory results, especially if the figures to be measured, as in the case of indicator diagrams, are much of the same shape, for in this case the operator soon learns where to put the point R.

Integrators serve to evaluate an integral, and especially a definite integral $\int_a^b f(x) dx$, where $f(x)$ is given graphically, or, if given by a formula, is first represented graphically. If we plot out the curve whose equation is $y=f(x)$, the integral $\int y dx$ between the proper limits represents the area of a figure bounded by the curve, the axis of x, and the ordinates at $x=a$, $x=b$. Hence if the curve is drawn, any planimeter may be used for finding the value of the integral. In this sense planimeters are integrators. In fact, a planimeter may often be used with advantage to solve problems more complicated than the determination of a mere area, by converting the one problem graphically into the other. We give an example:—

Let the problem be to determine for the figure ABG (Fig. 18), not only the area, but also the first and second moment with

Integrators.

Let the problem be to determine for the figure ABG (Fig. 18), not only the area, but also the first and second moment with

regard to the axis XX. At a distance a draw a line, C'D', parallel to XX. In the figure draw a number of lines parallel to AB. Let CD be one of them. Draw C and D vertically upwards to C'D', join these points to some selected point O in XX, and mark the points C₁D₁ where OC' and OD' cut CD. Do this for a sufficient number of lines, and join the points C₁D₁, thus obtained. This gives a new curve, which may be called the first derived curve. By the same process get a new curve from this, the second

Fig. 18.

derived curve. By aid of a planimeter determine the areas P, P₁, P₂, of these three curves. Then, if \bar{x} is the distance of the mass-centre of the given area from XX; \bar{x}' the same quantity for the first derived figure, and $I = Ak^2$ the moment of inertia of the first figure, k its radius of gyration, with regard to XX as axis, the following relations are easily proved:—

$$P\bar{x} = aP_1; P_1\bar{x}_1 = aP_2; I = aP_1\bar{x}_1 = a^2P_1P_2; k^2 = \bar{x}\bar{x}_1,$$

which determine P, \bar{x} and I or k . Amsler has constructed an integrator which serves to determine these quantities by guiding a tracer once round the boundary of the given figure (see below). Again, it may be required to find the value of an integral $\int y\phi(x)dx$ between given limits where $\phi(x)$ is a simple function like $\sin nx$, and where y is given as the ordinate of a curve. The harmonic analysers described below are examples of instruments for evaluating such integrals.

Amsler has modified his planimeter in such a manner that instead of the area it gives the first or second moment of a figure about an axis in its plane. This instrument, known as the Amsler's integrator or moment-planimeter, has one tracer but three recording wheels. It is mounted on a carriage which runs on a straight rail (Fig. 19). This carries a horizontal disc A, movable about a vertical axis Q. Slightly more than half the circumference is circular with radius $2a$, the other part with radius $3a$. Against these gear two discs, B and C, with radii a ; their axes are fixed in the carriage. The first part extends to the left to a rod OT of length l , on which a recording wheel W is mounted. The discs B and C have also recording wheels, W₁ and W₂. The centres of the three discs are in a line perpendicular to the rail. If now T is guided round a figure F, O will move to and fro in a straight line. This part is therefore a simple planimeter, in which the one end of the arm moves in a straight line instead of in a circular arc. Consequently, the "roll" of W will record the area of the figure. Imagine now that the discs B and C also receive arms of length l from the centres of the discs to points T₁ and T₂, and in the directions of the axes of the wheels. Then these arms with their wheels will again be planimeters. As T is guided round the given figure F, these points T₁ and T₂ will

describe closed curves, F₁ and F₂, and the "rolls" of W₁ and W₂ will give their areas A₁ and A₂. Let XX (Fig. 20) denote the line, parallel to the rail, on which O moves; then when T lies on this line, the arm BT₁ is perpendicular to XX, and CT₂ parallel to it. If OT is turned through an angle θ , clockwise,

Fig. 20.

BT₁ will turn counter-clockwise through an angle 2θ , and CT₂ through an angle 3θ , also counter-clockwise. If in this position T is moved through a distance x parallel to the axis XX, the points T₁ and T₂ will move parallel to it through an equal distance. If now the first arm is turned through a small angle $d\theta$, moved back through a distance x , and lastly turned back through the angle $d\theta$, the tracer T will have described the boundary of a small strip of area. We divide the given figure into such strips. Then to every such strip will correspond a strip of equal length x of the figures described by T₁ and T₂. The distances of the points, T, T₁, T₂, from the axis XX may be called y, y_1, y_2 .

These have the values

$$y = l \sin \theta, y_1 = l \cos 2\theta, y_2 = -l \sin 3\theta,$$

from which

$$dy = l \cos \theta d\theta, dy_1 = -2l \sin 2\theta d\theta, dy_2 = -3l \cos 3\theta d\theta.$$

Fig. 19.

The areas of the three strips are respectively

$$dA = xdy, dA_1 = xdy_1, dA_2 = xdy_2.$$

Now dy_1 can be written $dy_1 = -4l \sin \theta \cos \theta d\theta = -4 \sin \theta dy$;

therefore

$$dA_1 = -4 \sin \theta \cdot dA = -\frac{4}{7} y dA;$$

whence

$$A_1 = -\frac{4}{7} \int y dA = -\frac{4}{7} A \bar{y},$$

where A is the area of the given figure, and \bar{y} the distance of its mass-centre from the axis XX . But A_1 is the area of the second figure F_1 , which is proportional to the reading of W_1 . Hence we may say

$$A \bar{y} = C_1 w_1,$$

where C_1 is a constant depending on the dimensions of the instrument. The negative sign in the expression for A_1 is got rid of by numbering the wheel W_1 the other way round.

Again

$$\begin{aligned} dy_2 &= -3l \cos \theta \{4 \cos^2 \theta - 3\} d\theta = -3 \{4 \cos^2 \theta - 3\} dy \\ &= -3 \left\{ \frac{4}{l^2} y^2 - 3 \right\} dy, \end{aligned}$$

which gives

$$dA_2 = -\frac{12}{l^2} y^2 dA + 9 dA,$$

and

$$A_2 = -\frac{12}{l^2} \int y^2 dA + 9A.$$

But the integral gives the moment of inertia I of the area A about the axis XX . As A_2 is proportional to the roll of w_2 , A to that of W , we can write

$$\begin{aligned} I &= Cw - C_2 w_2, \\ A \bar{y} &= C_1 w_1, \\ A &= C_0 w. \end{aligned}$$

If a line be drawn parallel to the axis XX at the distance \bar{y} , it will pass through the mass-centre of the given figure. If this represents the section of a beam subject to bending, this line gives for a proper choice of XX the neutral fibre. The moment of inertia for it will be $I + A\bar{y}^2$. Thus the instrument gives at once all those quantities which are required for calculating the strength of the beam under bending. One chief use of this integrator is for the calculation of the displacement and stability of a ship from the drawings of a number of sections. It will be noticed that the length of the figure in the direction of XX is only limited by the length of the rail.

This integrator is also made in a simplified form without the wheel W_2 . It then gives the area and first moment of any figure.

While an integrator determines the value of a definite integral, hence a mere constant, **Integrators** give the value of an indefinite integral, which is a function of x . Analytically if y is a given function $f(x)$ of x and

$$Y = \int_c^x y dx \text{ or } Y = \int y dx + \text{const.}$$

the function Y has to be determined from the condition

$$\frac{dY}{dx} = y.$$

Graphically $y=f(x)$ is either given by a curve, or the graph of the equation is drawn: y , therefore, and similarly Y , is a length. But $\frac{dY}{dx}$ is in this case a mere number, and cannot equal a length y . Hence we introduce an arbitrary constant length a , the unit to which the integrator draws the curve, and write

$$\frac{dY}{dx} = \frac{y}{a} \text{ and } aY = \int y dx.$$

Now for the Y -curve $\frac{dY}{dx} = \tan \phi$, where ϕ is the angle between the tangent to the curve, and the axis of x . Our condition therefore becomes

$$\tan \phi = \frac{y}{a}$$

This ϕ is easily constructed for any given point on the y -curve:—From the foot B' (Fig. 21) of the ordinate $y=B'B$ set off, as in the figure, $B'D=a$, then angle $BDB'=\phi$. Let now DB' with a perpendicular $B'B$ move along the axis of x , whilst B follows the y -curve, then a pen P on $B'B$ will describe the Y -curve provided it moves at every moment in a direction parallel to BD . The object of the integrator is to draw this new curve when the tracer of the instrument is guided along the y -curve.

Fig. 21.

The first to describe such instruments was Abdank - Abakanowicz, who in 1839 published a book in which a variety of mechanisms to obtain the object in question are described. Some years later Coradi, in Zürich, carried out his ideas. Before this was done, Mr C. V. Boys, without knowing of Abdank-Abakanowicz's work, actually made an integrator which was exhibited at the Physical Society in 1881. Both make use of a sharp edge wheel. Such a wheel will not slip sideways; it will roll forwards along the line in which its plane intersects the plane of the paper, and while rolling will be able to turn gradually about its point of contact. If then the angle between its direction of rolling and the x -axis be always equal to ϕ , the wheel will roll along the Y -curve required. The axis of x is fixed only in direction; shifting it parallel to itself adds a constant to Y , and this gives the arbitrary constant of integration.

In fact, if Y shall vanish for $x=c$, or if

$$Y = \int_c^x y dx,$$

then the axis of x has to be drawn through that point on the y -curve which corresponds to $x=c$.

In Coradi's integrator a rectangular frame $F_1F_2F_3F_4$ (Fig. 22) rests with four rollers R on the drawing board, and can roll freely in the direction OX , which will be called the axis of the instrument.

Fig. 22.

On the front edge F_1F_2 travels a carriage AA' supported at A' on another rail. A bar DB can turn about D , fixed to the frame in its axis, and slide through a point B fixed in the carriage AA' . Along it a block K can slide. On the back edge F_3F_4 of the frame another carriage C travels. It holds a vertical spindle with the knife-edge wheel at the bottom. At right angles to the plane of

the wheel, the spindle has an arm GH, which is kept parallel to a similar arm attached to K perpendicular to DB. The plane of the knife-edge wheel r is therefore always parallel to DB. If now the point B is made to follow a curve whose y is measured from OX, we have in the triangle BDB', with the angle ϕ at D,

$$\tan \phi = y/a,$$

where $a = DB'$ is the constant base to which the instrument works. The point of contact of the wheel r or any point of the carriage C will therefore always move in a direction making an angle ϕ with the axis of x , whilst it moves in the x -direction through the same distance as the point B on the y -curve—that is to say, it will trace out the integral curve required, and so will any point rigidly connected with the carriage C. A pen P attached to this carriage will therefore draw the integral curve. Instead of moving B along the y -curve, a tracer T fixed to the carriage A is guided along it. For using the instrument the carriage is placed on the drawing-board with the front edge parallel to the axis of y , the carriage A being clamped in the central position with B on the axis AE. The tracer is then placed on the x -axis of the y -curve and clamped to the carriage, and the instrument is ready for use. As it is convenient to have the integral curve placed directly opposite to the y -curve so that corresponding values of y or Y are drawn on the same line, a pen P' is fixed to C in a line with the tracer.

Boys' integrator was invented during a sleepless night, and during the following days carried out as a working model, which gives highly satisfactory results. It is ingenious in its simplicity, and a direct realization as a mechanism of the principles explained in connexion with Fig. 21. The line B'B is represented by the edge of an ordinary T-square sliding against the edge of a drawing-board. The points B and P are connected by two rods BE and EP, jointed at E. At B, E, and P are small pulleys of equal diameters. Over these an endless string runs, ensuring that the pulleys at B and P always turn through equal

angles. The pulley at B is fixed to a rod which passes through the point D, which itself is fixed in the T-square. The pulley at P carries the knife-edge wheel. If then B and P are kept on the edge of the T-square, and B is guided along the curve, the wheel at P will roll along the Y-curve, it having been originally set parallel to BD. To give the wheel at P sufficient grip on the paper, a small loaded three-wheeled carriage, the knife-edge wheel P being one of its wheels, is added. If a piece of copying paper is inserted between the wheel P and the drawing paper the Y-curve is drawn very sharply.

Integrators have also been constructed, by aid of which ordinary differential equations, especially linear ones, can be solved, the solution being given as a curve. The first suggestion in this direction was made by Lord Kelvin. So far no really useful instrument has been made, although the ideas seem sufficiently developed to enable a skilful instrument-maker to produce one should there be sufficient demand for it. Sometimes a combination of graphical work with an integrator will serve the purpose. This is the case if the variables are separated, hence if the equation

$$Xdx + Ydy = 0$$

has to be integrated where $X = \phi(x)$, $Y = \psi(y)$ are given as curves. If we write

$$au = \int Xdx, \quad av = \int Ydy$$

then u as a function of x , and v as a function of y can be graphically found by the integrator. The general solution is then

$$u + v = c$$

with the condition, for the determination for c , that $y = y_0$, for $x = x_0$. This determines $c = u_0 + v_0$, where u_0 and v_0 are known from the graphs of u and v . From this the solution as a curve giving y a function of x can be drawn:—For any x take u from its graph, and find the y for which $v = c - u$, plotting these y against their x gives the curve required.

Fig. 23.

If a periodic function y of x is given by its graph for one period c , it can, according to the theory of Fourier's Series, be expanded in a series.

Harmonic analysers.

$$y = A_0 + A_1 \cos \theta + A_2 \cos 2\theta + \dots + A_n \cos n\theta + \dots + B_1 \sin \theta + B_2 \sin 2\theta + \dots + B_n \sin n\theta + \dots$$

where $\theta = \frac{2\pi x}{c}$

The absolute term A_0 equals the mean ordinates of the curve, and can therefore be determined by any planimeter. The other coefficients are

$$A_n = \frac{1}{\pi} \int_0^{2\pi} y \cos n\theta \cdot d\theta; \quad B_n = \frac{1}{\pi} \int_0^{2\pi} y \sin n\theta \cdot d\theta.$$

A harmonic analyser is an instrument which determines these integrals, and is therefore an integrator. The first instrument of this kind is due to Lord Kelvin (*Proc. Roy. Soc.* vol. xxiv., 1876). Since then several others have been invented (see Dyck's *Catalogue*; Henrici, *Phil. Mag.*, July 1894; *Phys. Soc.*, 9th March; Sharp, *Phil. Mag.*, July 1894; *Phys. Soc.*, 13th April). In Lord Kelvin's instrument the curve to be analysed is drawn on a cylinder whose circumference equals the period c , and the sine and cosine terms of the integral are introduced by aid of simple harmonic motion. Sommerfeld and Wiechert, of Königsberg, avoid this motion by turning the cylinder about an axis perpendicular to that of the cylinder. Both these machines are large, and practically fixtures in the room where they are used. The first has done good work in the Meteorological Office in London in the analysis of meteorological curves. Quite different and simpler constructions

can be used, if the integrals determining A_n and B_n be integrated by parts. This gives

$$nA_n = -\frac{1}{\pi} \int_0^{2\pi} \sin n\theta \cdot dy; \quad nB_n = \frac{1}{\pi} \int_0^{2\pi} \cos n\theta \cdot dy.$$

An analyser presently to be described, based on these forms, has been constructed by Coradi in Zürich (1894). Lastly a most powerful analyser has been invented by Michelson and Stratton (U.S.A.) (*Phil. Mag.*, 1898), which will also be described.

The *Henrici-Coradi* analyser has to add up the values of $dy \cdot \sin n\theta$ and $dy \cdot \cos n\theta$. But these are the components of dy in two directions perpendicular to each other, of which one makes an angle $n\theta$ with the axis of x or of θ . This decomposition can be performed by Amshler's registering wheels. Let two of these be mounted, perpendicular to each other, in one horizontal frame which can be turned about a vertical axis, the wheels resting on the paper on which the curve is drawn. When the tracer is placed on the curve at the point $\theta = 0$ the one axis is parallel to the axis of θ . As the tracer follows the curve the frame is made to turn through an angle $n\theta$. At the same time the frame moves with the tracer in the direction of y . For a small motion the two wheels will then register just the components required, and during the continued motion of the tracer along the curve the wheels will add these components, and thus give the values of nA_n and nB_n . The factors $1/\pi$ and $-1/\pi$ are taken account of in the graduation of the wheels. The readings have then to be divided by n to give the coefficients required. Coradi's realization of this idea will be understood from Fig. 23. The frame PP' of the instrument rests on three rollers E, E', and D. The first two drive an axis with a

disc C on it. It is placed parallel to the axis of x of the curve. The tracer is attached to a carriage WW which runs on the rail P. As it follows the curve this carriage moves through a distance x whilst the whole instrument runs forward through a distance y . The wheel C turns through an angle proportional, during each small motion, to dy . On it rests a glass sphere, which will therefore also turn about its horizontal axis proportionally to dy . The registering frame is suspended by aid of a spindle S, having a disc H. It is turned by aid of a wire connected with the carriage WW, and turns n times round as the tracer describes the whole length of the curve. The registering wheels R, R' rest against the glass sphere and give the values nA_n and nB_n . The value of n can be altered by changing the disc H into one of different diameter. It is also possible to mount on the same frame a number of spindles with registering wheels and glass spheres, each of the latter resting on a separate disc C. As many as five have been introduced. One guiding of the tracer over the curve gives then at once the ten coefficients A_n and B_n for $n=1$ to 5.

Michelson and Stratton Analyser.—All the calculating machines and integrators considered so far have been kinematic. We have now to describe a most remarkable instrument based on the equilibrium of a rigid body under the action of springs. The body itself for rigidity's sake is made a hollow cylinder H, shown in Fig. 24 in end view. It can turn about its axis, being supported on knife-edges O. To it springs are attached at the prolongation of a horizontal diameter; to the left a series of n small springs s , all alike, side by side at equal intervals at a distance a from the axis of the knife-edges; to the right a single spring S at distance b . These springs are supposed to follow Hooke's law. If the elongation beyond the natural length of a spring is λ , the force asserted by it is $p=k\lambda$. Let for the position of equilibrium l , L be respectively the elongation of a small and the large spring k , K their constants, then is

$$nkla = Klb.$$

The position now obtained will be called the *normal* one. Now let the top ends C of the small springs be movable, and let any one of them be raised through a distance y . This will turn the body H, B will move down through a distance z and A up through a distance $\frac{a}{b}z$. The new forces thus introduced will be in equilibrium if

$$ak \left(\sum y - n \frac{a}{b} z \right) = bKz.$$

$$z = \frac{\sum y}{n \frac{a}{b} + \frac{bK}{a}} = \frac{\sum y}{n \left(\frac{a}{b} + \frac{l}{L} \right)}.$$

Or

This shows that the displacement z of B is proportional to the sum of the displacements y of the tops of the small springs. The arrangement can therefore be used for the addition of a number of displacements. The instrument made has eighty small springs, and the authors state that from the experience gained there is no impossibility of increasing their number even to a thousand. The displacement z , which necessarily must be small, can be enlarged by aid of a lever OT. To regulate the displacements y of the points C (Fig. 24) each spring is attached to a lever EC, fulcrum E. To this again a long rod FG is fixed by aid of a joint at F. The lower end of this rod rests on another lever GP, fulcrum N, at a changeable distance $y''=NG$ from N. The elongation y of any spring s can thus be produced by a motion of P. If P be raised through a distance y' , then the displacement y of C will be proportional to $y'y''$; it is, say, equal to $\mu y'y''$ where μ is the same for all springs. Now let the points C, and with it the springs s , the levers, &c.,

Fig. 24.

be numbered C_0, C_1, C_2, \dots . There will be a zero-position for the points P all in a straight horizontal line. When in this position the points C will also be in a line, and this we take as axis of x . On it the points C_0, C_1, C_2, \dots follow at equal distances, say each equal to h . The point C_k lies at the distance kh which gives the x of this point. Suppose now that the rods FG are all set at unit distance

NG from N, and that the points P be raised so as to form points in a continuous curve $y'=\phi(x)$, then the points C will lie in a curve $y=\mu\phi(x)$. The area of this curve is

$$\mu \int_0^c \phi(x) dx.$$

Approximately this equals $\sum h y = h \sum y$. Hence we have

$$\int_0^c \phi(x) dx = \frac{h}{\mu} \sum y = \frac{\lambda h}{\mu} z,$$

where z is the displacement of the point B which can be measured. The curve $y'=\phi(x)$ may be supposed cut out as a templet. By putting this under the points P the area of the curve is thus determined—the instrument is a simple integrator.

The integral can be made more general by varying the distances $NG=y''$. These can be set to form another curve $y''=f(x)$. We have now $y=\mu y' y'' = \mu f(x) \phi(x)$, and get as before

$$\int_0^c f(x) \phi(x) dx = \frac{\lambda h}{\mu} z.$$

These integrals are obtained by the addition of ordinates, and therefore by an approximate method. But the ordinates are numerous, there being 79 of them, and the results are in consequence very accurate. The displacement z of B is small, but it can be magnified by taking the reading of a point T' on the lever AB. The actual reading is done at point T connected with T' by a long vertical rod. At T either a scale can be placed or a drawing-board, on which a pen at T marks the displacement.

If the points G are set so that the distances NG on the different levers are proportional to the terms of a numerical series

$$u_0 + u_1 + u_2 + \dots$$

and if all P be moved through the same distance, then z will be proportional to the sum of this series up to 80 terms. We get an *Addition Machine*.

The use of the machine can, however, be still further extended. Let a templet with a curve $y'=\phi(\xi)$ be set under each point P at right angles to the axis of x hence parallel to the plane of the figure. Let these templets form sections of a continuous surface, then each section parallel to the axis of x will form a curve like the old $y'=\phi(x)$, but with a variable parameter ξ or $y'=\phi(\xi, x)$. For each value of ξ the displacement of T will give the integral

$$Y = \int_0^c f(x) \phi(\xi x) dx = F(\xi), \dots \dots (1)$$

where Y equals the displacement of T to some scale dependent on the constants of the instrument.

If the whole block of templets be now pushed under the points P and if the drawing-board be moved at the same rate, then the pen T will draw the curve $Y=F(\xi)$. The instrument now is an *integrating parameter*.

Having thus shown how the lever with its springs can be made to serve a variety of purposes, we return to the description of the actual instrument constructed. The machine serves first of all to sum up a series of harmonic motions or to draw the curve

$$Y = a_1 \cos x + a_2 \cos 2x + a_3 \cos 3x + \dots \dots (2)$$

The motion of the points P_1, P_2, \dots is here made harmonic by aid of a series of excentric discs arranged so that for one revolution of the first the other discs complete 2, 3, . . . revolutions. They are all driven by one handle. These discs take the place of the templets described before. The distances NG are made equal to the amplitudes a_1, a_2, a_3, \dots . The drawing-board, moved forward by the turning of the handle, now receives a curve of which (2) is the equation. If all excentrics are turned through a right angle a sine-series can be added up.

It is a remarkable fact that the same machine can be used as a harmonic analyser of a given curve.

Let the curve to be analysed be set off along the levers NG so that in the old notation it is

$$y'' = f(x);$$

whilst the curves $y'=\phi(x\xi)$ are replaced by the excentrics, hence ξ by the angle θ through which the first excentric is turned, so that $y'_k = \cos k\theta$.

But $kh=x$ and $n\theta=\pi$, n being the number of springs s , and π taking the place of c . This makes

$$k\theta = \frac{n}{\pi} x.$$

Hence our instrument draws a curve which gives the integral (1) in the form

$$y = \frac{2}{\pi} \int_0^\pi f(x) \cos \left(\frac{n}{\pi} \theta x \right) dx$$

as a function of θ .

But this integral becomes the coefficient a_m in the cosine expansion if we make

$$\frac{n}{\pi}\theta = m \text{ or } \theta = m\frac{\pi}{n}.$$

The ordinates of the curve at the values $\theta = \frac{\pi}{n}, 2\frac{\pi}{n}, \dots$ give therefore all coefficients up to $m=80$.

The curve shows at a glance which and how many of the coefficients are of importance.

The instrument is described in *Phil. Mag.* vol. xlv., 1898. A number of curves drawn by it are given, and also examples of the analysis of curves for which the coefficients a_m are known. These indicate that a remarkable accuracy is obtained. (O. H.)

Matlock, a town in the western parliamentary division of Derbyshire, England, 17 miles north by west of Derby, on the river Derwent and the Midland Railway (Matlock Bridge station). The newer portion, Matlock Bank, famous for its hydropathics, has been connected with the older by a tramway worked by a single cable, with a gradient said to be the steepest in the world. Population of urban district (1891), 5285; (1901), 5980; of the separate urban district of Matlock Bath (1901), 1816.

Matsugata, Count (1835—), Japanese statesman, was born at Kagoshima in 1835, being a son of a *samurai* of the Satsuma clan. On the completion of the feudal revolution of 1868 he was appointed governor of the province of Tosa, and having served six years in this office, was transferred to Tôkyô as assistant minister of finance. As representative of Japan at the Paris Exhibition of 1878, he took the opportunity afforded by his mission to study the financial systems of the great European Powers. On his return home, he held for a short time in 1880 the portfolio of home affairs, and was in 1881 appointed minister of finance. The condition of the currency of Japan was at that time deplorable, and national bankruptcy threatened. The coinage had not only been seriously debased during the closing years of the Tokugawa régime, but large quantities of paper currency had been issued and circulated, both by many of the feudal lords and by the central government itself, as a temporary expedient for filling an impoverished exchequer. In 1878 depreciation had set in, and the inconvertible paper had by the close of 1881 grown to such an extent that it was then at a discount of 80 per cent. as compared with silver. Count Matsugata showed the Government the danger of the situation, and urged that the issue of further paper currency should be stopped at once, the expenses of administration curtailed, and the resulting surplus of revenue used in the redemption of the paper currency and in the creation of a specie reserve. These proposals were acted upon: the Bank of Japan was established, and the right of issuing convertible notes given to it; and within three years of the initiation of these financial reforms, the paper currency, largely reduced in quantity, was restored to its full par value with silver, and the currency as a whole placed on a solvent basis. From this time forward Japan's commercial and military advancement continued to make uninterrupted progress. But *pari passu* with the extraordinary impetus given to its trade by the successful conclusion of the war with China, the national expenditure enormously increased, rising within a few years from 80 to 250 million yen. The task of providing for this expenditure fell entirely on Count Matsugata, who had to face strong opposition on the part of the Diet. But he distributed the increased taxation so equally, and chose its subjects so wisely, that the ordinary administrative expenditure and the interest on the national debt were fully provided for, while the extraordinary expenditure for military purposes was met from the Chinese indemnity. As far back as 1878 Count

Matsugata perceived the advantages of a gold standard, but it was not until 1897 that his scheme could be realized. In this year the Bill authorizing it was under his auspices submitted to the Diet and passed; and with this financial achievement Count Matsugata saw the fulfilment of his ideas of financial reform, which were conceived during his first visit to Europe. Count Matsugata twice held the office of prime minister (1891-92, 1896-97), and during both his administrations he combined the portfolio of finance with the premiership; in 1899 and 1900 he was minister of finance only. His name in Japanese history is indissolubly connected with the financial progress of his country at the end of the 19th century.

Matteawan, a village of Dutchess county, New York, U.S.A., near the eastern bank of the Hudson river, opposite Newburg, in the south-eastern part of the state, on the New York, New Haven, and Hartford (New England), and the Newburg, Dutchess, and Connecticut Railways. Population (1890), 4278; (1900), 5807, of whom 1044 were foreign-born.

Matto Grosso, a state of Brazil, extending between 7° 30' and 24° 10' S. and 50° 35' and 65° 10' W., having on the N. the states of Amazonas and Pará, on the W. Bolivia, on the S. Paraguay, and on the E. Goyaz, Minas Geraes, Sao Paulo, and Paraná. Its area covers 532,708 square miles. It is drained in the north by the Tocantins-Araguaya, and in the south by the Paraná-Parahyba. Its mineral wealth is considerable, though many of the mines are of little importance. Gold, iron, diamonds, and rock-salt are amongst the minerals that occur in greater or smaller quantities. The rearing of cattle is the chief agricultural pursuit. Population (1870), 60,417; (1890), 92,827. The capital, Cuyabá (8000), is in telegraphic connexion with Rio de Janeiro.

Mattoon, a city of Coles county, Illinois, U.S.A., south-east of the centre of the state, at the intersection of the Cleveland, Cincinnati, Chicago and St Louis, the Illinois Central, and the Peoria, Decatur and Evansville Railways, at an altitude of 726 feet. It is in a rich farming country, for which it serves as a collecting and distributing point. Population (1890), 6833; (1900), 9622, of whom 430 were foreign-born and 227 were negroes.

Maubeuge, a town in the arrondissement of Avesnes, department of Nord, France, 48 miles south-east of Lille, on the railway from Paris. Large glass-works are now important industrial features. The town forms the nucleus of an entrenched camp, of which the perimeter is about 18 miles. Population (1891), 11,953; (1901), 20,826.

Maupassant, Henri René Albert Guy de (1850-1893), French novelist and poet, was born at the Château of Miromesnil in the department of Seine-Inférieure on 5th August 1850. His grandfather, a landed proprietor of a good Lorraine family, owned an estate at Neuville-Champ-d'Oisel near Rouen, and bequeathed a moderate fortune to his son, a Paris stockbroker, who married Mademoiselle Laure Lepoitevin. Maupassant was educated at Yvetot and at the Rouen lycée. A copy of verses entitled *Le Dieu Créateur*, written during his year of philosophy, has been preserved and printed. He entered the ministry of marine, and was promoted by M. Bardoux to the Cabinet de l'Instruction Publique. A pleasant legend says that, in a report by his official chief, Maupassant is mentioned as not reaching the standard of the department in the matter of style. He may very well have been an unsatisfactory clerk, as he divided his time

between rowing expeditions and attending the literary gatherings at the house of Gustave Flaubert, who was not, as he is often alleged to be, connected with Maupassant by any blood tie. Flaubert was not his uncle, nor his cousin, nor even his godfather, but merely an old friend of Madame de Maupassant, whom he had known from childhood. At the literary meetings Maupassant seldom shared in the conversation. Upon those who met him—Tourgenieff, Alphonse Daudet, M. Catulle Mendès, M. José-Maria de Heredia, and M. Zola—he left the impression of a simple young athlete. Even Flaubert, to whom Maupassant submitted some sketches, was not greatly struck by their talent, though he encouraged the youth to persevere. Maupassant's first essay was a dramatic piece twice given at Étretat in 1873 before an audience which included Tourgenieff, Flaubert, and Meilhac. In this indecorous performance, of which nothing more is heard, Maupassant played the part of a woman. During the next seven years he served a severe apprenticeship to Flaubert, who by this time realized his pupil's exceptional gifts. In 1880 Maupassant published a volume of poems, *Des Vers*, against which the public prosecutor of Étampes took proceedings that were finally withdrawn through the influence of the senator Cordier. From Flaubert, who had himself been prosecuted for his first book, *Madame Bovary*, there came a letter congratulating the poet on the similarity between their first literary experiences. *Des Vers* is an extremely interesting experiment, which shows Maupassant to us still hesitating in his choice of a medium; but he recognized that it was not wholly satisfactory, and that its chief deficiency—the absence of verbal melody—was fatal. Later in the same year he contributed to the *Soirées de Médan*, a collection of short stories by MM. Zola, J.-K. Huysmans, Henry Céard, Léon Hennique, and Paul Alexis; and in *Boule de Suif* the young unknown author revealed himself to his amazed collaborators and to the public as an admirable writer of prose and a consummate master of the *conte*. There is perhaps no other instance in modern literary history of a writer beginning, as a fully-equipped artist, with a genuine masterpiece. This early success was quickly followed by another. The volume entitled *La Maison Tellier* (1881) confirmed the first impression, and vanquished even those who were repelled by the author's choice of subjects. In *Mademoiselle Fifi* (1883) he repeated his previous triumphs as a *conteur*, and in this same year he, for the first time, attempted to write on a larger scale. Choosing to portray the life of a blameless girl, unfortunate in her marriage, unfortunate in her son, consistently unfortunate in every circumstance of existence, he leaves her, ruined and prematurely old, clinging to the tragic hope, which time, as one feels, will belie, that she may find happiness in her grandson. This picture of an average woman undergoing the constant agony of disillusion Maupassant calls *Une Vie* (1883), and as in modern literature there is no finer example of cruel observation, so there is no sadder book than this, while the effect of extreme truthfulness which it conveys justifies its sub-title—*Phumble vérité*. Certain passages of *Une Vie* are of such a character that the sale of the volume at railway bookstalls was forbidden throughout France. The matter was brought before the Chamber of Deputies, with the result of drawing still more attention to the book, and of advertising the *Contes de la Bécasse* (1883), a collection of stories as improper as they are clever. *Au Soleil* (1884), a book of travels which has the eminent qualities of lucid observation and exact description, was less read than *Clair de Lune*, *Miss Harriet*, *Les Sœurs Rondoli*, and *Yvette*, all published in 1884, when Maupassant's powers were at

their highest level. Three further collections of short tales, entitled *Contes et Nouvelles*, *Monsieur Parent*, and *Contes du Jour et de la Nuit*, issued in 1885, proved that while the author's vision was as incomparable as ever, his fecundity had not improved his impeccable form. To 1885 also belongs an elaborate novel, *Bel-Ami*, the cynical history of a particularly detestable, brutal scoundrel who makes his way in the world by means of his handsome face. Maupassant is here no less vivid in realizing his literary men, financiers, and frivolous women than in dealing with his favourite peasants, boors, and servants, to whom he returned in *Toine* (1886) and in *La Petite Roque* (1886). About this time appeared the first symptoms of the malady which destroyed him; he wrote less, and though the novel *Mont-Oriol* (1887) shows him apparently in undiminished possession of his faculty, *Le Horla* (1887) suggests that he was already subject to alarming hallucinations. Restored to some extent by a sea-voyage, recorded in *Sur l'Eau* (1888), he went back to short stories in *Le Rosier de Madame Husson* (1888), a burst of Rabelaisian humour equal to anything he had ever written. His novels *Pierre et Jean* (1888), *Fort comme la Mort* (1889), and *Notre Cœur* (1890) are penetrating studies touched with a profounder sympathy than had hitherto distinguished him; and this softening into pity for the tragedy of life is deepened in some of the tales included in *Inutile Beauté* (1890). One of these, *Le Champ d'Oliviers*, is an unsurpassable example of poignant, emotional narrative. With *La Vie errante* (1890), a volume of travels, Maupassant's career practically closed. *Musotte*, a theatrical piece written in collaboration with M. Jacques Normand, was published in 1891. By this time inherited nervous maladies, aggravated by excessive physical exercises and by the imprudent use of drugs, had undermined his constitution. He began to take an interest in religious problems, and for a while made the *Imitation* his handbook; but his misanthropy deepened, and he suffered from curious delusions as to his wealth and rank. A victim of *la folie des grandeurs*, he drank the waters at Aix-les-Bains during the summer of 1891, and retired to Cannes, where he purposed passing the winter. The singularities of conduct which had been observed at Aix-les-Bains grew more and more marked. Maupassant's reason slowly gave way. On 6th January 1892 he attempted suicide, and was removed to Paris, where he died in the most painful circumstances on 6th July 1893. He is buried in the cemetery of Montparnasse. The opening chapters of two projected novels, *L'Angélu* and *L'Âme Étrangère*, were found among his papers; these, with *La Paix du Ménage*, a comedy in two acts, and two collections of tales, *Le Père Milton* (1898) and *Le Colporteur* (1899), have been published posthumously. A correspondence, called *Amitié amoureuse* (1897), and dedicated to his mother, is probably unauthentic. Among the prefaces which he wrote for the works of others, only one—an introduction to a French prose version of Mr Swinburne's *Poems and Ballads*—is likely to interest English readers.

Maupassant began as a follower of Flaubert and of M. Zola, but, whatever the masters may have called themselves, they both remained essentially *romantiques*. The pupil is the last of the "naturalists": he even destroyed naturalism, since he did all that can be done in that direction. He had no psychology, no theories of art, no moral or strong social prejudices, no disturbing imagination, no wealth of perplexing ideas. It is no paradox to say that his marked limitations made him the incomparable artist that he was. Undisturbed by any external influence, his marvellous vision enabled him to become a supreme observer, and, given his literary sense, the rest was simple. He prided himself in having no invention; he described nothing that he had not seen. The peasants whom he had

known as a boy figure in a score of tales ; what he saw in Government offices is set down in *L'Héritage* ; from Algiers he gathers the material for *Maroca* ; he drinks the waters and builds up *Mont-Oriol* ; he enters journalism, constructs *Bel-Ami*, and, for the sake of precision, makes his brother, Hervé de Maupassant, sit for the infamous hero's portrait ; he sees fashionable society, and, though it wearied him intensely, he transcribes its life in *Fort comme la Mort* and *Notre Cœur*. Fundamentally he finds all men alike. In every grade he finds the same ferocious, cunning, animal instincts at work : it is not a gay world, but he knows no other ; he is possessed by the dread of growing old, of ceasing to enjoy ; the horror of death haunts him like a spectre. It is an extremely simple outlook. Maupassant does not prefer good to bad, one man to another ; he never pauses to argue about the meaning of life, a senseless thing which has the one advantage of yielding materials for art ; his one aim is to discover the hidden aspect of visible things, to relate what he has observed, to give an objective rendering of it, and he has seen so intensely and so serenely that he is the most exact transcriber in literature. And as the substance is, so is the form : his style is exceedingly simple and, exceedingly strong ; he uses no rare or superfluous word, and is content to use the humblest word if only it conveys the exact picture of the thing seen. In ten years he produced some thirty volumes. With the exception of *Pierre et Jean*, his novels, excellent as they are, scarcely represent him at his best, and of over two hundred *contes*, a proportion must be rejected. But enough will remain to vindicate his claim to a permanent place in literature as an unmatched observer and the most perfect master of the short story. (J. F.-K.)

Mauritius, known also as ISLE OF FRANCE, an island in the south-western portion of the Indian Ocean, 600 miles east of Madagascar, 1500 miles east of the coast of Africa, 20° 10' S. and 57° 35' E. Its mineral productions are few and unimportant. The climate of the island cannot be considered very healthy, and there were several very fatal epidemics during the latter half of the 19th century. In common with Réunion, it is exposed to severe and destructive cyclones, but the soil is of considerable fertility, and the greater portion of the level plains is now a vast sugar plantation. Port Louis, the capital, had in 1891 a population of about 70,000, but in 1897 this had diminished to 55,000, a large number of its former inhabitants now living at villages on the railway lines stretching to the north and south of the island. These lines had in 1896 a total length of 105 miles. In recent years extensive explorations have been made in the beds of some of the ancient lakes, and considerable quantities of the bones of the extinct dodo, solitaire, and other short-winged birds, which were almost or quite incapable of flight, have been discovered. Some changes have taken place since 1882 in the governmental arrangements of the island. The Legislative Council now consists of 27 members, 10 being elected, 8 *ex officio*, and 9 nominated by the governor. In 1884-85 a constitutional change was made by the introduction of an elective element into the legislature. Under a moderate franchise ten members are now elected, one for each of the eight divisions of the island, and two for Port Louis.

The following statistics show the revenue and expenditure of the colony :—

	1888.	1898.	1900.
Revenue	Rs. 8,574,058	Rs. 7,620,320	Rs. 9,179,975
Expenditure	7,771,579	8,131,470	8,568,943

At the beginning of 1901 the public debt stood at £1,189,284.

General Trade.

	1888.	1898.	1900.
Exports . .	Rs. 32,291,978	Rs. 27,537,930	Rs. 30,982,673
Imports . .	15,341,202	24,006,970	22,810,778

British Trade.

	1888.	1898.	1900.
Exports . .	£275,546	£100,863	£232,566
Imports . .	253,928	239,242	377,174

Of the above general trade, the following were the principal items of export :—

	1888.	1898.	1900.
Sugar value .	Rs. 28,754,798	Rs. 24,727,690	Rs. 28,836,355
Rum	297,882	85,800	224,086
Cocoa-nut oil . .	107,275	59,180	46,479
Vanilla	311,630	140,100	169,821
Aloe-fibre . . .	690,858	427,130	940,432

A great change is taking place in the population. Most of Port Louis has passed from Europeans to Hindus or Chinese, and the sugar estates of the island are being similarly transferred. During the 5 years 1896-1900 land to the value of 9,084,490 rupees was purchased by Hindus from Mauritian planters, and since 1864 real property to the value of 24,159,945 rupees. The following are statistics of the population, including all nationalities :—

	1881.	1891.	1901.
Males	209,560	207,103	} 380,040
Females . . .	151,287	164,552	
Total	360,847	371,655	

Of the above, the Hindu coolie proportion was :—

	249,064	255,500	261,136
--	---------	---------	---------

By the census of 1891 the general population, as respects religion, was divided as follows : Hindus (pagan), 209,079 ; Roman Catholics, 115,438 ; Mahommedans, 34,763 ; Protestants, 7307.

Primary education is provided in 75 Government and 98 denominational and aided schools, the number of pupils on the roll in 1900 being 19,481, with an average attendance of 12,235. Secondary education is provided in the Royal College at Curepipe (temporarily), with 169 pupils ; the royal college school, at the same place, with 116 pupils ; and the royal college school at Port Louis, with 54 pupils. (J. Sr*.)

Mawkmai (called by the Burmese *Maukme*), one of the largest states in the eastern division of the southern Shan States of Burma. It lies approximately between 19° 30' and 20° 30' N. and 97° 30' and 98° 15' E., and has an area of 2787 square miles. The central portion of the state consists of a wide plain well watered and under rice cultivation. The rest is chiefly hills, in ranges running north and south. There is a good deal of teak in the state, but it has been ruinously worked. The Sawbwa now works as contractor for Government, which takes one-third of the net profits. Rice is the chief crop, but much tobacco of good quality is grown in the Langkó district on the Têng river. There is also a great deal of cattle-breeding. The population was estimated in 1892 at 18,693, over two-thirds of whom were Shans and the remainder Taungthu (4502), Burmese (552), Yangsek (445), and Red Karens (312). The Sawbwa pays a tribute of Rs.13,000 for the period 1898-1902. The capital, MAWKMAI, stands in a fine paddy plain in 20° 9' N. and 97° 25' E. It had about 150 houses when it first submitted in 1887, but was burnt out by the Red Karens in the following year. It has since recovered. There are very fine orange groves a few miles south of the town at Kantu-awn.

Max Müller, Friedrich (1823-1900), Orientalist and comparative philologist, was born at Dessau, 6th December 1823, being the son of Wilhelm Müller, celebrated for his phil-Hellenic lyrics. He lost his father before he had attained his fourth year, but received a very careful education. The elder Müller had endeared himself

to the most intellectual circles in Germany by his amiable character and his genuine poetic gift, and it was his son's good fortune to meet in his youth with a succession of eminent friends, who, already interested in him for his father's sake, and charmed by the qualities which they discovered in the young man himself, powerfully aided him by advice and patronage. Mendelssohn dissuaded him from indulging his natural bent to the study of music; Professor Brockhaus of the University of Leipzig, where Max Müller matriculated in 1841, induced him to take up Sanskrit; Bopp, at the University of Berlin (1844), made the Sanskrit student a scientific comparative philologist; Schelling, at the same university, inspired him with a love for metaphysical speculation, though failing to attract him to his own philosophy; Burnouf, at Paris in the following year, by teaching him Zend, started him on the track of inquiry into the science of comparative religion, and impelled him to edit the *Rig Veda*; and when, in 1846, Max Müller came to England upon this errand, Bunsen, in conjunction with Professor H. H. Wilson, prevailed upon the East India Company to undertake the expense of publication. Up to this time Max Müller had lived the life of a poor student, supporting himself partly by copying manuscripts, but Bunsen's introductions to Queen Victoria and the Prince Consort, and to Oxford University, laid the foundation for him of fame and fortune. In 1848 the printing of his *Rig Veda* at the University Press obliged him to settle in Oxford, a step which decided his future career. He arrived at a favourable conjuncture; the Tractarian strife, which had so long thrust learning into the background, was just over, and Oxford was becoming accessible to modern ideas. The young German excited curiosity and interest, and it

was soon discovered that, although a genuine scholar, he was no mere bookworm. Part of his social success was due to his readiness to exert his musical talents at private parties. Max Müller was speedily subjugated by the *genius loci*. He was appointed deputy Taylorian professor of modern languages in 1850, and the German Government failed to tempt him back to Strasburg. In the following year he was made M.A. and honorary fellow of Christ Church, and in 1858 he was elected a fellow of All Souls. In 1854 the Crimean war gave him the opportunity of utilizing his Oriental learning in vocabularies and schemes of transliteration. In 1857 he successfully essayed another kind of literature in his beautiful story *Deutsche Liebe*, written both in German and English. He had by this time become an extensive contributor to English periodical literature, and had written several of the essays subsequently collected as *Chips from a German Workshop*. The most important of them was the fascinating essay on "Comparative Mythology" in the *Oxford Essays* for 1856. His valuable *History of Ancient Sanskrit Literature*, so far as it illustrates the primitive religion

of the Brahmans (and hence the Vedic period only), was published in 1859.

Though Max Müller's reputation was that of a comparative philologist and Orientalist, his professorial duties at Oxford were long confined to lecturing on modern languages, or at least their mediæval forms. In 1860 the death of Horace Hayman Wilson, professor of Sanskrit, seemed to open a more congenial sphere to him. His claims to the succession seemed incontestable, for his opponent, Monier Williams, though well qualified as a Sanskritist, lacked Max Müller's brilliant versatility, and although educated at Oxford, had held no University office. But Max Müller was a Liberal, and the friend of Liberals in University matters, in politics, and in theology, and this consideration united with his foreign birth to bring the country clergy in such hosts to the poll

that the voice of resident Oxford was overborne, and Monier Williams was elected by a large majority. It was the one great disappointment of Max Müller's life, and he never quite recovered from it. It was, nevertheless, serviceable to his influence and reputation by permitting him to enter upon a wider field of subjects than would have been possible otherwise. Directly, Sanskrit philology received little more from him, except in connexion with his later undertaking of *The Sacred Books of the East*, but indirectly he exalted it more than any predecessor by proclaiming its commanding position in the history of the human intellect by his *Science of Language*, two courses of lectures delivered at the Royal Institution in 1861 and 1863. Max Müller ought not to be described as "the introducer of comparative philology into England." Prichard had proved the Aryan affinities of the Celtic languages by the methods of

PROFESSOR MAX MÜLLER.

(From a photograph by Elliott and Fry, London.)

comparative philology so long before as 1831; Winning's *Manual of Comparative Philology* had been published in 1838; the discoveries of Bopp and Pott and Pictet had been recognized in brilliant articles in the *Quarterly Review*, and had guided the researches of Rawlinson. But Max Müller undoubtedly did far more to popularize the subject than had been done, or could have been done, by any predecessor. He was on less sure ground in another department of the study of language—the problem of its origin. His speculations on this subject brought him into collision with the Darwinians, though they were perhaps no more capable than himself of seeing more than one side of the question. He wrote upon it as a disciple of Kant, whose *Critique of Pure Reason* he translated. His essays on mythology are among the most delightful of his writings, but their value is somewhat impaired by a too uncompromising adherence to the seductive generalization of the solar myth.

Max Müller's studies in mythology led him to another field of activity in which his influence was more durable and extensive, that of the comparative science of religions.

Here, so far as Great Britain is concerned, he does deserve the fame of an originator, and his *Introduction to the Science of Religion* (1873—the same year in which he lectured on the subject, at Dean Stanley's invitation, in Westminster Abbey, this being the only occasion on which a layman had given an address there) marks an epoch. It was followed by other works of importance, especially the four volumes of Gifford lectures, delivered between 1888 and 1892; but the most tangible result of the impulse he had given was the publication under his editorship, from 1875 onwards, of *The Sacred Books of the East*, in fifty-one volumes, including indexes, all but three of which appeared under his superintendence during his lifetime. These comprise translations by the most competent scholars of all the really important non-Christian scriptures of Oriental nations, which can now for the first time be appreciated without a knowledge of the original languages. The advantage to the comparative study of religions is unspeakable; considering, indeed, how few are able to read more than one or two Oriental languages, it may be said to have rendered such a comparison for the first time possible. If the positive value of the books thus interpreted proves less than was anticipated, this fact, too, has its useful side. *Omne ignotum can no longer be taken pro magnifico*. Max Müller also wrote on Indian philosophy in his latter years, and his exertions to stimulate search for Oriental manuscripts and inscriptions were rewarded with important discoveries of early Buddhist scriptures, in their Indian form, made in Japan. He was on particularly friendly terms with native Japanese scholars, and after his death his library was purchased by the University of Tôkyô.

In 1868 Max Müller had been indemnified for his disappointment over the Sanskrit professorship by the establishment of a chair of comparative philology, to be filled by him. He retired, however, from the actual duties of the post in 1875, when entering upon the editorship of *The Sacred Books of the East*. The most remarkable external events of his latter years were his delivery of lectures at the restored University of Strasburg in 1872, when he devoted his honorarium to the endowment of a Sanskrit lectureship, and his presidency over the International Congress of Orientalists in 1892. But his days, if uneventful, were busy. He participated in every movement at Oxford of which he could approve, and was intimate with nearly all its men of light and leading; he was a curator of the Bodleian Library, and a delegate of the University Press. He was acquainted with most of the crowned heads of Europe, and was an especial favourite with the English royal family. His hospitality was ample, especially to visitors from India, where he was far better known than any other European Orientalist. His distinctions, conferred by foreign governments and learned societies, were innumerable, and, having been naturalized shortly after his arrival in England, he received the high honour of being made a privy councillor. In 1898 and 1899 he published autobiographical reminiscences under the title of *Auld Lang Syne*. He was writing a more detailed autobiography when overtaken by death on 28th October 1900, shortly after he had written, in the *Nineteenth Century*, on the religions of China, and vindicated the British cause in South Africa against Professor Mommsen. Max Müller married in 1859 Georgiana Adelaide Grenfell, sister of the wives of Charles Kingsley and J. A. Froude. One of his daughters, Mrs Conybeare, distinguished herself by a translation of Scherer's *History of German Literature*, but died shortly afterwards.

Though undoubtedly a great scholar, Max Müller did not so much represent scholarship pure and simple as her hybrid types—the scholar-author and the scholar-courtier. In the former capacity, though manifesting

little of the originality of genius, he rendered vast service by popularizing high truths among high minds. In his public and social character he represented Oriental studies with a brilliancy, and conferred upon them a distinction, which they had not previously enjoyed in Great Britain. There were drawbacks in both respects: the author was too prone to build upon insecure foundations, and the man of the world incurred censure for failings which may perhaps be best indicated by the remark that he seemed too much of a diplomatist. Vanity and kindred faults may easily be detected in his writings, but the sum of foibles seems insignificant in comparison with the life of intense labour dedicated to the service of culture and humanity. (R. G.)

Maxwelltown. See DUMFRIES.

Mayaguez, a city situated at the west end of Porto Rico, 72 miles west-south-west of San Juan. It was founded in 1752, is the third in population and the most pleasant and most beautiful city of the island. Its streets are wide, shaded, and lined with handsome residences and shops. The public buildings are numerous and commodious, including a cathedral, theatre, the court-house (Ayuntamiento), hospital, barracks, and custom-house. The city has a public library and excellent water works. It is lighted by electricity, and until recently possessed the only tramway on the island. Mayaguez Playa, where the shipping is carried on, as at Ponce, is about three miles from the main city. Much coffee is exported. Population (1899), about 15,187.

Mayavaram, a town of British India, in the Tanjore district of Madras, on the Cauvery river; junction on the South Indian railway, 174 miles south of Madras. Population (1891), 23,765; municipal income (1897-98), Rs.35,830. It makes a speciality of the fine cotton cloth known as Kornad from the suburb in which the weavers live. The municipal high school had 417 pupils in 1897-98.

Maybole, a burgh of barony and police burgh of Ayrshire, Scotland, 9 miles south by west of Ayr by rail. The four principal boot factories employ 1700 hands, and the trade of 1899 made a record. The manufacture of agricultural implements is also a staple industry. The municipal buildings are modern. One of the public schools has a secondary department. Population (1881), 4474; (1901), 5892.

Mayen, a town of Prussia, in the Rhine province, on the east side of the Eifel, 16 miles west of Coblenz. It has lava and slate quarries, various textile industries, tanneries, oil and flour mills, and tobacco factories. It has fragments of its mediæval walls, and a mediæval keep (restored in 1893-94). Population (1885), 8440; (1900), 11,961.

Mayence. See MAINZ.

Mayenne, a department of the north-west of France, watered by the Mayenne.

Area, 1987 square miles. The population, 340,063 in 1886, numbered 311,207 in 1901. Births in 1899, 7003, of which 290 were illegitimate; deaths, 6851; marriages, 2362. There were in 1896, 626 primary schools, with 45,000 pupils, 5 per cent. of the population being illiterate. The land under cultivation amounted in 1896 to 1,183,677 acres, 889,611 acres being plough-land and almost all the rest grass land. The wheat crop of 1899 was valued at £1,200,000; meslin, £156,000; barley, £472,000; oats, £320,000; buckwheat, £120,000; potatoes, £148,000; mangold-wurzel, £232,000. Natural pastures yielded £532,000; hemp, £11,000; flax, £6400; apples, £168,000. The live stock included 78,550 horses, 292,080 cattle, 72,660 sheep, and 76,360 pigs. Mining in 1898 produced only 35,000 metric tons of coal. Spinning at Laval

and at Château-Gontier is the only industry of a department which is almost exclusively agricultural. Laval, the capital, had in 1901 30,356 inhabitants.

Mayenne, chief town of arrondissement and railway station, department of Mayenne, France, 18 miles north by east of Laval. A statue of Joan of Arc was erected in 1896. The "cloth" manufacture consists of tickings, linens, handkerchiefs, and calicoes. There is a departmental asylum, and a practical school of agriculture about three miles from the town. Population (1891), 7386; (1901), 10,125.

Mayhew, Henry (1812-1887), English author, son of a London solicitor, was born in 1812. He began to study law under his father, but soon gave it up for writing. With Gilbert à Beckett, in 1831, he started the first of several ephemeral papers, which introduced him to journalism; and he had a fairly successful opening with one or two farces. His brothers HORACE (1816-1872), and AUGUSTUS SEPTIMUS (1826-1875), also took to authorship, and with them Henry occasionally collaborated, notably with the younger in stories like *The Greatest Plague of Life* (1847), and in *Acting Charades* (1850). In 1841 Henry Mayhew was one of the leading spirits in the foundation of *Punch*, of which he was for the first two years joint-editor with Mark Lemon. He afterwards figured as a writer on all kinds of subjects, and published a number of volumes of no permanent reputation—humorous stories, travel, practical handbooks, and journalism of various sorts. He is credited with being the first to "write up" the poverty side of London life from a philanthropic point of view; with the collaboration of other writers he published *London Labour and London Poor* (1851; completed 1864) and other works on the subject, which had considerable influence at the time. He died in London, 25th July 1887. HORACE MAYHEW also contributed to *Punch* up to 1852, and was the author of several humorous publications and plays. Both his and his brother Augustus's volumes were enriched by Cruikshank's illustrations, and their survival is mainly due to that.

Mayo, a maritime county of Ireland, province of Connaught.

Population.—The area of the administrative county in 1900 was 1,327,777 acres, of which 157,279 were tillage, 534,764 pasture, 429 fallow, 8870 plantation, 278,151 turf bog, 44,517 marsh, 232,644 barren mountain, and 71,123 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, includes two electoral divisions formerly situated in Galway, and three electoral divisions formerly situated in Sligo, but is diminished by two electoral divisions now added to other counties. The population in 1881 was 245,212, in 1891, 219,034, and in 1901, 202,627, of whom 99,058 were males and 103,569 females, divided as follows among the different religions:—Roman Catholics, 198,014; Protestant Episcopalians, 3757; Presbyterians, 562; Methodists, 166; and other denominations, 128. The decrease of population between 1881 and 1891 was 10·68 per cent., and between 1891 and 1901, 7·3 per cent. The average number of persons to an acre was ·16 in 1891 and ·15 in 1901. Of the total population in 1891, 207,754 persons inhabited the rural districts, being an average of 191 persons to each square mile under crops and pasture. The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R.C.	Pr. Ep.	Presb.	Meth.
Read and write	57,401	53,673	111,074	56·1	88·8	93·4	94·5
Read only	10,118	11,349	21,467	11·2	5·8	3·3	3·5
Illiterate	27,848	34,661	62,509	32·7	5·4	3·3	2·0

The percentage of illiterates among Roman Catholics in 1881 was 45·9. In 1891 there were three superior schools with 251 pupils (Roman Catholics 233, and Protestants 18), and 410 primary schools with 30,840 pupils (Roman Catholics 30,008, and Protestants 832). The number of pupils on the rolls of the National schools

on 31st December 1900 was 37,402, of whom 36,707 were Roman Catholics and 695 Protestants.

The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	6013	3277	844
1891	5058	3339	703
1900	4491	2817	808

In 1900 the birth-rate per thousand was 22·2, and the death-rate 13·9; the rate of illegitimacy was ·3 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 164,291, of whom 74,924 were males and 89,367 females. The chief towns in the county are Ballina, Westport, and Castlebar.

Administration.—The county is divided into four parliamentary divisions—North, South, East, and West, the number of registered electors in 1901 being respectively 7655, 8412, 8204, and 8412. The rateable value in 1900 was £318,829. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises three urban and eight rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900. The figures for 1900 are for the new administrative county:—

Year.	Wheat.	Oats.	Barley, Flax, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	1046	62,830	8717	56,728	8497	8856	42,739	179,843
1891	1700	45,326	8582	43,478	7695	8881	48,020	153,677
1895	1112	44,234	8021	42,144	7904	4547	59,310	162,272
1900	1211	40,841	8339	89,104	6825	5480	61,079	157,379

In 1900 the total value of the cereal and other crops was estimated at £1,091,683. The number of acres under pasture in 1881 was 545,040, in 1891, 547,279, and in 1900, 534,764.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	21,293	20,424	166,527	251,108	48,216	6122	677,610
1891	18,718	23,566	174,983	351,343	58,316	8979	751,992
1895	21,190	23,623	180,830	308,148	67,854	7855	775,500
1900	19,479	24,418	191,497	361,978	74,746	8486	917,657

The number of milch cows in 1891 was 52,710, and in 1900, 57,432. Mayo supports more sheep than any other county in Ireland except Galway. It is estimated that the total value of cattle, sheep, and pigs for 1900 was £3,343,604. In 1900 the number of holdings not exceeding 1 acre was 2104; between 1 and 5, 3490; between 5 and 15, 15,180; between 15 and 30, 9544; between 30 and 50, 2905; between 50 and 100, 1690; between 100 and 200, 751; between 200 and 500, 459; and above 500, 198—total, 36,341. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901 was 759, amounting to £193,273. The number of loans for agricultural improvements sanctioned under sect. 31 of the Land Act, 1881, between 1882 and 1901, was 986, and the amount issued was £63,649. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1901, was £232,761.

Fisheries.—The number of boats registered in 1900 in the deep-sea and coast fishing districts of Keel, Belmullet, and Ballycasle was 485, employing 2449 hands. The number of persons employed in the same year in the salmon-fishing district of Ballina was 450.

(W. H. Po.)

Mayotte. See COMORO ISLANDS.

Maysville, a city of Kentucky, U.S.A., capital of Mason county, on the Ohio river, in the north-eastern part of the state, at an altitude of 511 feet. It is on the Chesapeake and Ohio and the Louisville and Nashville railways, in a farming region, and has varied manufactures. Population (1890), 5358; (1900), 6423, of whom 237 were foreign-born and 1155 were negroes.

Mazagan (*El Jadida*), the port for Marrakesh (from which it is 110 miles nearly due north), Morocco. It

does a considerable grain and wool trade. It was built by the Portuguese in 1509, and abandoned by them in 1769, the inhabitants settling at New Mazagan, in Brazil. There are European merchants, vice-consuls, and missionaries. The exports increased from £125,416 in 1896 to £360,577 in 1900, and the imports from £156,866 in 1896 to £281,690 in 1900. The port was cleared in the same two years by totals of 130,883 and 189,013 tons respectively. Population, about 10,000.

Mazamet, a town in the arrondissement of Castres, department of Tarn, France, 33 miles in direct line south-south-east of Albi, on the railway from Castres to St Pons. Manufacturing activity has greatly increased, and now includes important tanneries and leather-dressing works. About 10 establishments are employed in wool-spinning, and 22 in the manufacture of "swanskins" and flannels. The total annual value of manufactured products is about £800,000. Extensive commerce is carried on in wool and raw hides from Argentina, Australia, and Cape Colony. There is a large model dairy. Population, about 10,000.

Mazarron, a town of Spain, in the province of Murcia, to the east of Cartagena, four miles from the coast. Its population was in 1887, 16,454, and in 1897, 17,047. There are soap and flour mills and metallurgic factories. The mountains near contain rich beds of iron and lead ores, in working which one company employs 1200 workmen. A railway five miles long unites Mazarron to the port, where there is a suburb with 2500 inhabitants (mostly engaged in fisheries and coasting trade). There are barracks, a custom-house, and important lead works. Outside of the suburb there are salt-pans, most of the proceeds of which are exported to Galicia. The total output of the Mazarron lead mines in 1898 was nearly 87,000 tons. About 450 vessels visit the port annually, importing chiefly coal, machinery, timber, salt fish, and flour, and exporting iron ore, copper, and argentiferous lead. The total imports in 1898 amounted to 40,968 tons, and the total exports to 50,120 tons. The trade is largely with Great Britain.

Mazatlan, a town and port of Mexico, in the state of Sinaloa, on the Pacific. It is the leading commercial and industrial Mexican town on the Pacific, and is a port of call of several steamship lines. It has a weather bureau, a fine custom-house and other public buildings, also tramways and a chamber of commerce. The depth of water on the bar varies from 12 to 15 feet. Population (1895), 15,852.

Meade, George Gordon (1815-1872), American soldier, was born in Cadiz, Spain, 31st December 1815. Graduating at the United States Military Academy in 1835, he served in Florida in the 3rd United States Artillery against the Seminoles. Resigning from the army in 1836, he became a civil engineer and constructor of railways, and was soon engaged under the War Department in the survey of the Delta of the Mississippi. In 1842 he was appointed a lieutenant in the corps of the topographical engineers. In the war with Mexico he was successively on the staff of General Zachary Taylor, General William J. Worth, and General Robert Patterson, and was brevetted for gallant conduct. Until the Civil War he was engaged mainly on the lighthouse board and in the survey of the North-Western Lakes, of which he had charge, having reached the rank of captain of topographical engineers. He was considered a conservative, scientific, and highly intellectual engineer, and had proved himself a model officer in the field and under fire. In 1861 he was appointed a brigadier-general in the United States Volunteers, and had command of the 2nd Brigade of the

Pennsylvania Reserves in the army of the Potomac under General M'Call. He was in the battles of Mechanicsville and Gaines's Mills, and being severely wounded at the advance at New Market Cross-Roads on the day before the battle of Malvern Hill, he was absent from his command until the second battle of Bull Run, after which he obtained the command of the Reserve Division. At the battle of South Mountain he distinguished himself by his skill and intrepidity, and when General Joseph Hooker was wounded he succeeded to the command of the 1st corps of the army on the field of battle. He was especially mentioned for the services of his command at the battle of Fredericksburg, and was promoted to the rank of major-general.

In December he was placed in permanent command of the fifth army corps. At the battle of Chancellorsville he displayed great intrepidity and energy, and a thorough comprehension of the situation, and was appointed to the command of the army of the Potomac in June 1863, on the eve of the Gettysburg campaign. The details of the problem he was now called upon to solve could not have been known to him in his previous subordinate position, but he justified the confidence which the better class of officers had always reposed in him. Upon ascertaining the position of the enemy he at once made dispositions to concentrate upon Gettysburg. In the famous three days' battle that followed, General Meade's plan proved to be the best possible in the circumstances, forcing the Confederates to attack the well-chosen Union position. In the result Meade with 84,000 men defeated the army of General Lee, numbering very nearly the same as the active portion of his own army, one of his corps not being engaged. Lee retreating to the Potomac, Meade followed by a longer route and proposed to attack on the morning of 14th July, but the enemy crossed the river during the night. Meade was the first Union commander to defeat Lee in the open field, and his victory was the turning-point of the war. He was rewarded with the commission of brigadier-general in the regular army. Until Lee's surrender at Appomattox Court House, Meade commanded the army of the Potomac. His manœuvres, when Lee attempted to pass to his right and obtain the position between him and Washington, were masterful; and the actions of Bristoe Station, Kelley's Ford, and Rappahannock Station, and the operations at Mile Run increased the confidence with which his army regarded him. Grant, commanding all the armies of the United States, joined the army of the Potomac in the spring of 1864, and remained with it until the end of the war; but he continued Meade in his command, and successfully urged his appointment as major-general in the regular army (18th August 1864), eulogizing him as the commander who had successfully met and defeated the best general and the strongest army on the Confederate side. After the war Meade commanded the military division of the Atlantic and the Department of the East until August 1868. He then took command of the military districts embracing Georgia and Alabama, and then of the Department of the South, comprising the same states together with South Carolina and Florida. At the time of his death he was in command of the military division of the Atlantic. He died at Philadelphia, 6th November 1872, of pneumonia, which was aggravated by complications resulting from the wound he received at New Market Cross-Roads in 1862. The degree of LL.D. was conferred upon him by Harvard University, and his scientific attainments were recognized by the American Philosophical Society and the Pennsylvania Academy of Natural Sciences. (A. s. w*.)

Meadville, a city of Pennsylvania, U.S.A., capital of Crawford county, on French Creek, in the north-western part of the state, at an altitude of 1078 feet. It is on the Erie, and the Pittsburg, Bessemer and Lake Erie railways, and its manufactures are varied. It is the seat of Allegheny College, a Methodist Episcopal institution, which in 1899 had 16 instructors and was attended by 299 students, including 111 women. Population (1890), 9520; (1900), 10,291, of whom 912 were foreign-born and 173 were negroes.

Measuring Instruments, Electric.—In all departments of electrical engineering, and in the applications of electrical science in the arts and industries, it is necessary to be able to make exact measurements of the electric quantities with which we are concerned. These are stated in certain units (see ELECTRICITY, IV.), and are practically ascertained by appliances called electric measuring instruments, which may be divided into various species and types, according to the nature of the measurement to be made and the scientific fact or principle on which they depend. They may be classified thus:—

- | | | |
|--------------------------------|---------------------------|-------------------|
| (a) <i>Electric current</i> | measuring instruments, or | Amperemeters. |
| (b) <i>Electric potential</i> | ” | or Voltmeters. |
| (c) <i>Electric power</i> | ” | or Wattmeters. |
| (d) <i>Electric resistance</i> | ” | or Ohmmeters. |
| (e) <i>Electric energy</i> | ” | or Ergmeters. |
| (f) <i>Electric quantity</i> | ” | or Coulombmeters. |

The last two classes include the chief types of electric house-meters. In addition, there are forms of instrument especially employed in connexion with alternating-current measurements, such as those for determining the *wave form* of periodic currents (see ELECTRICITY, III., and ELECTRICITY SUPPLY, II.), and those for determining the *frequency* and *power-factor* of alternating or periodic currents. We may then furthermore divide all the above instruments into various types, depending on their principles of construction, namely, (i.) *Electrodynamic*, (ii.) *Electromagnetic*, (iii.) *Electrothermal*, (iv.) *Electrostatic*, (v.) *Electrochemical*.

Instruments of each species can be made in some or all of the five types. Thus, for instance, current-measuring instruments may be electrodynamic, electromagnetic, or electrothermal, but not entirely electrostatic; whilst potential-measuring instruments may be of all the above types. Current-measuring instruments may be additionally divided into (1) *galvanometers* and (2) *amperemeters* or *ammeters*. Galvanometers are instruments that simply indicate the value of an electric current in some arbitrary units, whereas amperemeters or ammeters indicate its value directly in practical units or amperes. Under the head of electrodynamic current-measuring instruments are included such instruments as Siemens's electro-dynamometer, Lord Kelvin's ampere-balances, and various other forms of Weber's electro-dynamometer; under electromagnetic current-measuring instruments, those of Weston, Evershed, Nalder, Dobrovolsky, and others; and under electrothermal current-measuring instruments those of Hartmann and Braun, Holden and Cardew. An important class of current-measuring instruments may be called *potentiometer ammeters*. In these instruments the current to be measured is passed through a strip of metal of low resistance, and the fall in potential down this resistance is measured by a suitable voltmeter or potential-measuring instrument. The value of the current is deduced from the numerical quotient of the fall in potential by the resistance.

In the Siemens dynamometer (Fig. 1) there are two coils of wire, one fixed (F) and the other (D) suspended by a bundle of

silk fibres; the suspended coil embraces the fixed coil, and has its axis at right angles to it. The movable coil is attached to a fixed torsion head through a steel spiral spring (S), and carries an index-needle (I). The torsion head is provided with a circular scale of degrees. The terminals of the movable coil dip into fixed mercury cups (M M), by means of which one and the same current

Fig. 1.

can be sent through the fixed and movable coils, or, for some uses of the instrument, different currents may be sent through the two coils. In any case the mechanical forces brought into play depend upon the product or mean product of the values of the currents in the two coils. If, for instance, the same current is passed through the coils in series, the movable coil tends to twist round so that its axis comes more into line with that of the fixed coil, which can be brought back to its original position by applying to the torsion head (T) a twist, and thereby twisting the top end of the spiral spring. The angle through which T must be twisted to do this is proportional to the torque or couple thereby applied to the movable coil, and this couple is proportional to the square of the strength of the current flowing through the coils. Hence the square root of the twist given to the torsion head, multiplied by a constant, will be numerically equal to the value of the current in amperes. Since the direction of the force is not altered by reversing the direction of the current, the instrument is suitable for measuring alternating currents, provided that the time of free vibration of the movable coil is large compared with the periodic time of the current. Under these last conditions, however, when the same current traverses both coils, the instrument measures the square root of the mean of the equidistant values of the current during the cycle, or, as it is generally called, the *root-mean-square (R.M.S.) value* of the current. If two currents differing in phase but identical in frequency are passed through the two circuits, then the torque is proportional to the mean value of the product of the instantaneous values of the currents.¹

The details of Lord Kelvin's ampere-balances are described under ELECTRICITY, III., and it may therefore here simply be mentioned that these instruments are practically electro-dynamometers, in which a movable coil is displaced relatively to a fixed coil when the same current passes through them both, and the coils are brought back to their original position by the application of a torque or couple due to the position of a weight sliding along a scale attached to the movable coils.

One of the most convenient of the electromagnetic current-measuring instruments is the ammeter devised by Weston. In this there is a fixed permanent magnet prepared of a special steel, and so treated as to possess a very constant interpolar field. Between the poles of this magnet is placed a small circular coil fixed to an axis which is carried in jewelled bearings like those of a watch. The current is passed into and out of this coil by small and very flexible wires. The coil is constrained to take up a definite position by means of a fine spiral steel spring, and it carries an index-needle moving over a scale of degrees. The normal position of the coil is with its plane parallel to the direction of the magnetic field, but when a current passes through the coil it is deflected against the controlling couple due to the

¹ There are many electric measurements which can be effected by employing the two circuits, fixed and movable, of the electro-dynamometer separately, and passing through them two alternating currents differing in phase. For details of such measurements and use of the instrument the reader is referred to a treatise on *Alternating Currents of Electricity*, by T. H. Blakesley, 2nd ed., chap. xi., London, 1899; also to a valuable paper by Prof. H. A. Rowland in the *American Journal of Science*, December, 1897, or *Electrician*, vol. xl. p. 251.

spring, and takes up a definite position in accordance with the value of the current. The scale of the instrument is graduated to show the value of this current directly in amperes or milliamperes. One advantage of these Weston movable coil instruments is that the scale divisions for equal increments of current are very nearly equal, and, moreover, there is no dead or non-divided part of the scale. They are exceedingly useful for the measurement of continuous currents varying from a centiampere up to one or two deciamperes, and for the measurement of larger currents a resistance is included which shunts part of the current so that only a definitely-selected portion of it goes through the movable coil. They have, however, the disadvantage that they can only be used for continuous and unidirectional currents, and not for alternating currents.

The construction of a number of instruments used for the commercial measurement of electric currents depends upon the fact that a small mass of iron placed in a non-uniform magnetic field tends to move from places of weak to places of strong field. If a circular coil of insulated wire is placed with its plane vertical and axis horizontal, and if a small mass of iron is suspended from a pivoted arm so as to occupy a position somewhere near the centre of the coil, then when the coil is traversed by a current the iron will move from the position near the centre of the coil, where the field is weak, to a position near the inner surface of the coil, where the field is stronger. This motion can be resisted by the weight of the iron, and its movement indicated by the needle attached to the axis of rotation. In this manner an instrument can be constructed in which there is a definite position for the needle corresponding to every stated value of the current through the coil. Another method is to place a cylindrical coil or helix of wire in a vertical position, and so arrange a small piece of soft iron, balanced upon a pivoted arm, that it is situated near the mouth of the coil when no current is passing, but is drawn more or less into the coil when the current is started. Of such form are the amperemeters devised by von Dobrovolsky and others. A movable iron mass may be arranged to be drawn in between two fixed pieces of iron placed in the field of a fixed coil, as in the case of the instruments of Evershed.

Another large class of ammeters depend for their action upon the heating effect of the current. If a fine wire or number of fine wires joined in parallel are traversed by a current, they become heated. If they are contained in an enclosure which is kept at a constant temperature, the temperature of the wires will rise until the rate at which they lose energy by radiation is equal to the rate at which energy is dissipated in them by the current. The temperature will then remain constant, and can be measured by the linear elongation of the wire or wires if one end is fixed and the other end arranged to move an indicating device. Alternatively, both ends of the wire may be fixed, and the extent to which it sags on expansion may be measured by some suitable indicating gear, as in the instruments of Hartmann and Braun.

By far the most satisfactory method of measuring continuous currents is that involving the use of a *potentiometer* and a low resistance. An essential requisite in every electric laboratory is a set of strips of metal composed of some alloy not altering its resistance greatly with temperature (see *ELECTRICITY*, I.). These strips are cut and formed so as to have a resistance between two particular terminals, called *potential terminals*, of a known low value, such, for instance, as one-tenth, one-hundredth, or one-thousandth of an ohm. These are technically termed low-resistance strips. By means of the potentiometer and a Clark cell the difference of potential between the potential terminals of such a strip may be measured when a continuous current is flowing through it. The value of the current in amperes is then given by the quotient of this difference of potential in volts divided by the resistance of the strip in ohms. For measuring very large currents these resistance strips may consist of tubes of manganin cooled by water flowing through them. In this manner a very high current density can be employed. The advantage of using resistance strips for the measurement of continuous currents is that the voltmeter or potentiometer part of the instrument need not be in close proximity to the resistance strip. Thus the whole current passing out of a continuous-current generating station can be passed through a strip of platinoid of appropriate size and known resistance, and the current value determined by measuring with a suitable voltmeter the fall of pressure down the strip, the voltmeter being placed a mile away if necessary.

A good amperemeter should, in the first place, if possible, be suitable for use both with continuous currents and alternating currents. In the next place, its indications should be the same for the same true current value whether it has been just previously employed for measuring another larger current or not. In the third place, the scale divisions should, if possible, be equal, so that increments of currents

correspond to equal scale movements of the indicating needle; and fourthly, the correctness of its indications should not be affected by any heating effect of the current in the coils, or by the presence of external magnetic field. These requirements are seldom, if ever, complied with in the same instrument. In all *gravity* instruments, in which the controlling force is a couple due to a weight, a correction is necessary for the latitude of the place at which the apparatus is used. The value of the acceleration of gravity is about one-half per cent. greater at the poles of the earth than at the equator, the value of g in centimetres per second squared being 978.1 at the latter and 983.1 at the former. Hence a gravity instrument standardized and made correct for use in London would show an error of about one-quarter per cent. if used at the equator or North Pole. Again, in all instruments which depend upon the employment of soft iron moving in a magnetic field there is generally a *hysteresis* error, which will exhibit itself if two readings are taken with the same small current, but a reading with a very large current interpolated. A hysteresis error is indicated if the scale readings of the instrument are not the same when a series of currents in ascending magnitudes are passed through the instrument, and then the same currents in descending magnitudes, the reason being that the small mass of iron becomes magnetized and does not immediately demagnetize itself. Again, ammeters having a fixed permanent field magnet are affected by the action of stray magnetic fields; and this is also the case with dynamometer instruments like that of Siemens, which are liable to give inaccurate measurements of continuous currents owing to the influence of the horizontal magnetic field of the earth. A Siemens dynamometer, therefore, when being used with a continuous current should always be placed with the axis of the movable coil in the direction of the magnetic meridian, since the passage of a current through the movable coil does not then tend to disturb its position, apart from the effect produced by the field of the fixed coil.

Many of the above types of instruments can be employed as *Voltmeters* or *Potential Measuring Instruments* if they are wound with a wire of high resistance. To measure the difference of potential between two places we may measure the current which flows through a circuit of high resistance connecting these places, but it is an essential condition that the potential difference shall not be sensibly disturbed by such shunted current. Hence a voltmeter depending upon the flow of an electric current through the instrument, whether it be of the electrodynamic, electromagnetic, or electrothermal type, must be constructed with coils of wire having a resistance of several hundred, or preferably several thousand, ohms. Well-known types of voltmeters, corresponding to the Weston, Nalder, Dobrovolsky, and Evershed ammeters, are in use. It is preferable, however, when possible, to employ an electrostatic voltmeter. If two metal surfaces are kept at different potentials, there is a stress or mechanical force between them, drawing them together, which is proportional, other things being equal, to the square of the difference of potential. Hence the force required to maintain the plates in their original position is a measure of their difference of potential. Taking advantage of this principle, many well-known inventors have devised ingenious forms of *electrostatic voltmeters*. One of the best known of these is Lord Kelvin's multicellular voltmeter.

In this instrument (Fig. 2) there are two sets of fixed metal plates (F), connected together and having a quadrantal shape, that is, approximately the shape of a quarter of a circular disc. In the centre between them is suspended a "needle" (V), which consists of a light aluminium axis, to which are affixed a number of paddle-shaped aluminium blades. This needle is suspended by a fine platinum silver wire (W), and its normal position is such that

the aluminium paddle blades are just outside the quadrantal-shaped plates. If the needle is connected to one terminal of a circuit, and the fixed plates or cells to the other member of the circuit, and a difference of potential is created between them, then the movable needle is drawn in so that the aluminium blades are more included in the fixed plates. This movement is resisted by the torsional

Fig. 2.

rigidity of the suspending wire, and hence a fixed indicating needle attached to the movable system can be made to indicate directly on a scale the difference of potential between the terminals of the instrument in volts. Instruments of this kind have been constructed not only by Lord Kelvin, but also by Professor Ayrton and others, for measuring voltages from 10,000 volts down to one volt. They have the advantage of taking up no power, whereas an electromagnetic voltmeter, or one of any type depending on the flow of an electric current through it, if maintained permanently in connexion with a circuit, involves considerable expenditure of power. Take, for instance, an electrothermal voltmeter, such as the Cardew voltmeter, in which potential difference is measured by observing the elongation produced by the passage of current in a wire connected to the two points between which exists the difference of potential to be measured. Suppose that the wire has a resistance of 300 ohms, and is connected to two places differing in potential by 100 volts, the instrument then passes a current of one-third of an ampere, and takes up 33 watts in power. Since there are 8760 hours in a year, this instrument, if connected continuously to the circuit, would take up energy equal to 263,000 watt-hours, or 263 Board of Trade units per annum. If the production value of this energy is 1d. per unit, the working expenses of such a voltmeter are more than £1 per annum, and their capitalized value is about £10. Hence the advantage of an electrostatic instrument which takes up no power. Moreover, since the electrostatic instruments depend essentially upon the square of the difference of potential, their indications are irrespective of the sign of the difference of potential, and they can therefore be used for alternating as well as continuous currents.

Potentiometers.—For the exact measurement of difference of potential when continuous, no instrument is more convenient than the *potentiometer*. The places whose difference of potential is to be measured must be connected by a long fine-wire circuit of high resistance, preferably of platinoid, and wound non-inductively. This must be divided into sections, the ratio of the resistance of which is accurately known. In its commercial form the instrument consists of a series of resistance coils (*r*), generally joined in series with a uniform wire (*ab*) stretched over a scale (Fig. 3). The terminals of this resistance are connected to one or two secondary cells (*B*), an additional variable resistance (*R*) being interposed in the circuit. The current through this resistance is

then adjusted so that the fall in potential down the wire has a known value, equal say to one-thousandth of a volt per centimetre of the uniform scale wire. This is achieved in the following manner:—A high-resistance galvanometer (*G*), which may preferably be of the movable coil type, has been placed in series with it a Clark standard cell (*C*), and the two are connected as a shunt on

Fig. 3.

the potentiometer circuit. Over the slide wire a contact-maker is arranged so that contact may be made at any point on the scale. Let this be placed first at *x* so that the scale reading of the Clark cell corresponds with the value of the electromotive force of the Clark cell at the temperature at which the experiment is made. Thus the resistance wire of the potentiometer, *e.g.*, in Crompton's form, may consist of 14 coils of wire and of a slide wire equal in resistance to one of them, the scale under the wire being divided into a thousand parts. Taking the electromotive force of a Clark cell at 15° C. as equal to 1.4340 volts, the contact-maker on the slide wire is set to make contact at the 340th division on the wire, and the other terminal of the galvanometer circuit is connected to the end of the potentiometer wire. If then the current through the potentiometer wire is adjusted until the galvanometer shows no current, the fall in potential down the slide wire will be one-tenth-thousandth of a volt for each scale division. We may then measure any other potential difference by substituting for the Clark cell a known fractional part of the fall in potential down the high-resistance wire above mentioned, which is connected in between the two points the difference of potential of which is required. For example, if it is desired to measure a difference of potential of the order of 100 volts, a high resistance consisting of a wire of 100,000 ohms may be divided into two sections, resistances of which are in the ratio of 9 to 1, 99 to 1, or 999 to 1. From the ends of one of the smaller sections two wires are brought to the potentiometer, and connected in place of the Clark cell. By moving the contact-maker along the slide wire until the galvanometer shows no current, we can read off directly on the potentiometer scale the value of a known fractional part of the difference of potential which is to be measured, namely, one-tenth, one-hundredth, or one-thousandth, according to the fraction of the divided resistance employed. The potentiometer and the divided resistance constitute a sort of electrical scale-yard, by means of which any electromotive force or difference of potential can be compared with the electromotive force of a standard cell. Very convenient practical forms of potentiometer have been devised by Crompton, Nalder, Elliott Brothers, and Fleming.

Standard Cells.—In addition to the Clark standard cell above mentioned, the elements of which are mercury and zinc separated by a paste of mercurous sulphate mixed with a saturated solution of zinc sulphate, other voltaic standards of electromotive force are in use, such as the Weston cadmium cell, the Helmholtz calomel cell, and the standard Daniell cell. The Clark cell is made in two forms, the Board of Trade or tubular form, and the H form of cell devised by Lord Rayleigh. The German experts seem to favour the latter form; the specification issued by the Physikalisch-Technische Reichsanstalt of Berlin may be found in the *Electrician*, vol. xxxi. pp. 265-266. The electromotive force of the cell diminishes with rise of temperature, the Board of Trade value being 1.434 volts at 15° C.¹ and 1.434 (1 - 0.00077 (t - 15)) volts at t° C. A more exact expression is obtained if instead of 0.00077 the quantity 0.00078 + 0.000017 (t - 15) is used. In the Weston standard cell cadmium and cadmium sulphate are substituted for zinc and zinc sulphate; it has the advantage of a much smaller coefficient of temperature variation than the Clark cell. It is most conveniently made up in a glass vessel of H form, pure mercury and cadmium amalgam being the two elements (Fig. 4), and when made as directed below it has at t° C. an electromotive force *E_t* volts, such that

$$E_t = 1.019 [3.8 \times 10^{-5} (t - 20) - 0.065 \times 10^{-5} (t - 20)^2].$$

¹ According to K. Kahle and W. Wien, the electromotive force of the H form of Clark cell is 1.4322 volts at 15° C.

After the platinum wires have been sealed through the glass, a little aqua regia is placed in the cell legs until bubbles of gas arise from the platinum, when it is thrown out and replaced by a solution of mercurous nitrate. Then by the use of another piece of platinum as anode, mercury is electrolytically deposited upon the platinum, which may also be amalgamated by making it white hot in a Bunsen flame and plunging it in mercury. To prepare the cadmium amalgam, one part of pure cadmium is dissolved in six parts of pure mercury, and the product while warm and fluid is placed in one limb of the cell and warmed, to ensure perfect contact with the platinum wire.

Fig. 4.

The cadmium sulphate solution is prepared by digesting a saturated solution of cadmium sulphate with cadmium hydroxide to remove free acid, care being taken not to raise the temperature above 70° C., and then by digesting it still further with mercurous sulphate until no more precipitation occurs. The cadmium sulphate solution must be saturated and have free crystals of the salt in it. The mercurous sulphate must be free from acid, and made neutral by triturating with finely-divided mercury. In making the paste, so much cadmium sulphate must be added that a saturated solution of that salt is formed and is present in the cell. The cell has the electromotive force above stated if the amalgam of cadmium has from 6 to 13 parts of mercury to 1 of cadmium. The German investigators seem to have a great preference for the H form of cell, but it is clear that a narrow tubular cell of the British Board of Trade form not only comes more quickly to the temperature of the water bath in which it is placed, but is more certain to be wholly at one temperature.

In cases when great accuracy is not required, a Daniell cell can be used as a standard of electromotive force. The form designed by J. A. Fleming (*Phil. Mag.* vol. xx. p. 126) consists of a U tube, one leg of which contains a rod of pure amalgamated zinc, and the other a rod of freshly-electrotyped copper. The legs are filled with solutions of zinc sulphate and copper sulphate, the zinc rod being in the zinc sulphate and the copper rod in the copper sulphate. When so made, the cell has an electromotive force of 1.072 volts and no sensible temperature variation. The solutions are made by dissolving the purest recrystallized sulphate of copper and sulphate of zinc in distilled water. For the zinc solution, take 55.5 parts by weight of crystals of zinc sulphate ($ZnSO_4 \cdot 7OH_2$) and dissolve in 44.5 parts by weight of distilled water; the resulting solution should have a specific gravity of 1.200 at about 20° C. For the sulphate of copper solution, take 16.5 parts by weight of pure crystals of copper sulphate ($CuSO_4 \cdot 5OH_2$) and dissolve in 83.5 parts by weight of water; the resulting solution should have a specific gravity of 1.100 at 20° C. The solutions should be adjusted exactly to these densities and kept in stock bottles, from which the reservoirs of the cell should be filled up as required.

Instruments for the measurement of electric power are called *wattmeters*. The electric power taken up in a circuit traversed by a continuous current is measured in watts by the product of the current flowing through the circuit in amperes, and the difference of potential between the extremities of the circuit measured in volts. If the current is alternating, and the circuit is truly non-inductive or approximately inductionless, the mean value of the power taken up in the circuit is obtained by multiplying together the root-mean-square value of the current and the root-mean-square value of the potential difference. If, however, the circuit is inductive, as in an electromagnet or a transformer, then the mean power taken up in it is not given simply by the product of the above-mentioned root-mean-square values, but by this product multiplied by a fraction called the *power-factor*. If we are dealing with simple periodic or alternating currents, the variations in instantaneous value follow a simple sine law, and the power-factor becomes the cosine of the angle of lag or phase-difference angle between the current and the electromotive force (see ELECTRICITY, III.). An instrument for the measurement of electric

power can be constructed on the same plan as a Siemens dynamometer or a Kelvin ampere-balance, with this difference, that in a wattmeter the two circuits, fixed and movable, have separate terminals. One of these circuits, generally the fixed one, is traversed by the current passing through the power-absorbing circuit, and the movable coil is constructed of a fine high-resistance wire, the terminals of which are connected across the ends of the power-absorbing circuit. In these circumstances the fixed coil is traversed by a current which is the current through the power-absorbing circuit, and the movable coil is traversed by a current which is proportional to the potential difference of the ends of the power-absorbing circuit. If the circuit is inductive and the currents periodic, these two currents differ in phase. In any case, the mechanical couple that must be applied to the movable coil to bring it back to a fixed position with respect to the fixed coil is proportional to the mean value of the product of the instantaneous values of the currents at equidistant intervals of time during the period. But this last mean product is a measure of the mean power; hence the mechanical couple, and therefore the twist of the torsion head, required to restore the movable coil to its original position becomes a measure of the mean power taken up in the circuit tested.

If at any instant the current through the fixed coil is i , and the current through the movable coil is i_1 , then the torque to be applied to the movable coil to keep it in its zero position is proportional to the product ii_1 . Hence the mean value of the torque is proportional to the value of ii_1 during the phase, or is equal to $\frac{1}{T} \int_0^T ii_1 dt$ where T is the periodic time. If, therefore, the twist of the upper end of the spiral spring is θ , and D is a constant called the dynamometer constant, $D\theta = \frac{1}{T} \int_0^T ii_1 dt$.

If r is the resistance of the movable coil circuit, and e the potential difference of its ends, then $rD\theta = \frac{1}{T} \int_0^T iedt$. The integral on the right-hand side is the expression for the mean power P given to the circuit. Hence

$$rD\theta = P.$$

It has been shown that a power-measuring instrument, or wattmeter constructed in this manner, is available for the measurement not only of continuous but of alternating current-power. In measuring the power taken up in inductive circuits supplied at very high electric pressure, in which the difference of potential between the extremities of the circuit is, say, 2000 volts or upwards, an additional device is necessary in order to reduce the current passing through the movable coil to a convenient value. Either a sufficiently large non-inductive resistance may be put in series with the movable coil, or a closed iron circuit *step-down transformer* may be employed. The property of such a transformer is that a periodic electromotive force applied to its primary terminals produces a periodic electromotive force in the secondary circuit, which follows the same law of variation, but is reduced in absolute value by any required amount. Hence in employing a dynamometer wattmeter to measure power taken up in an alternating current circuit when the electromotive force is high, it is usual to join across the terminals of the circuit the step-down transformer, which reduces the voltage to any required amount, and to connect the movable coil of the wattmeter in series with the secondary circuit of this transformer if necessary through a resistance which preferably takes the form of one or more incandescent lamps.

The function of another important class of electric meters is to measure either the electric energy supplied to a circuit, or the electric quantity. If the pressure and current are uniform and unvarying, the electric energy is simply measured by the product of the electric power and

time, and the electric quantity is measured by the product of the electric current and the time. If the current is variable, the electric energy and the electric quantity are measured by the time-integrals of the power and the current respectively. Instruments which automatically measure these

Energy meters.

time-integrals are called *energy meters* and *quantity meters*, and of this kind are all those appliances which are also called electric *house-meters*, since they are used for measuring the supply of electric energy or electric quantity from public electric supply stations to customers connected therewith.

One simple form of energy meter is that of Mengarini, an instrument of the wattmeter type. It has a fixed coil traversed by the current passing into the energy-absorbing circuit or house, and a movable coil suspended by a bifilar arrangement with its axis at right angles to the fixed coil. The movable coil carries an index-pen moving over a revolving drum covered with paper, which is driven uniformly by clockwork. If it is connected to the terminals of the power-absorbing circuit, and the fixed coil traversed by the current, then it is deflected through an angle which is nearly proportional to the mean power being given to the circuit; the pen, therefore, will trace a line upon the drum, and when the paper is removed and laid out flat, the area of the curve included between the base line and the two vertical ordinates is proportional to the time-integral of the power supplied to the circuit. The instrument can therefore be easily calibrated so that the measurement of this area gives the power supplied to the circuit in any time in joules or Board of Trade units.¹ Another self-integrating wattmeter of this kind is that due to Elihu Thomson. It consists of a small electric motor, the armature and the field of which contain no iron. The former is a simple drum-wound armature, wound with fine wire and connected through a resistance with the terminals of the power-absorbing circuit; the field magnet consists of two coils of thick wire in series with the power-absorbing circuit. The armature shaft carries a copper disc which revolves between the poles of fixed permanent magnets, and is geared with a counting mechanism which records the number of its revolutions. When the instrument is connected up to the circuits, the mechanical driving power on the motor is proportional to the mean electric power taken up in the circuit measured, while the eddy currents set up in the copper disc exercise a retarding effect proportional to its speed. Hence the speed of the motor, if left to itself, is constant when the currents passing through it are unvarying, and varies as the mean power being taken up in the circuit to which it is connected. Accordingly, the number of revolutions in a given time are a measure of the total electric energy imparted to the circuit in that time. A similar motor-meter has been devised by Evershed. Another much-used form of energy meter or watt-hour meter is that of Aron. In this instrument there is a fixed coil, through which passes the whole current entering the power-absorbing circuit or house. Suspended over this is a movable coil which forms the bob of a clock pendulum, and this is wound with fine wire which is a shunt across the terminals of the power-absorbing circuit. The pendulum regulates a clock, which drives, through a differential gearing, a recording hand registering on a dial or dials the difference in the rate of this and another comparison clock with an ordinary pendulum and clock mechanism. The rate at which a pendulum vibrates being determined by its length and by the force acting on the bob, the rate of the first pendulum is controlled partly by gravity and partly by the force created by the attraction due to the currents in the fixed and movable coils. But this second quantity is proportional to the product of the values of the two currents in the two coils, that is, to the power passing through the instrument; hence the rate at which the clock movement governed by this pendulum gains or loses on the comparison clock is a measure of the power passing through the meter, and the total gain or loss of one clock over the other in any time is a measure of the total energy in watt-hours or Board of Trade units imparted to the circuit in that time.

Quantity meters are meters which measure the time-integral of a current in either ampere-hours or coulombs.

The simplest type depends upon electrolysis; Bastian's electrolytic meter is an example. In this instrument the current to be integrated passes through a dilute solution of sulphuric acid contained in a glass tube, the current entering and leaving by platinum electrodes. Since every ampere-hour which passes through the instrument liberates from the electrolyte 0.29829 of a

gramme of oxygen and 0.03738 of a gramme of hydrogen gas, and therefore diminishes the bulk of the electrolyte by a fixed amount, the total amount of electrolyte destroyed in any given time can be estimated by the fall in level of the liquid as seen in a gauge-glass. The electrolyte is prevented from evaporating by a little paraffin oil placed upon it, and the tube can be calibrated to show at once in Board of Trade units the amount of electric energy which has passed through the instrument, on the assumption that the potential difference between the two sides of the circuit is constant. The meter of course really records the total electric quantity which has passed through it, but on the supposition that that quantity is supplied at a constant voltage, the instrument may be used as an energy meter.

One of the earliest forms of electric house meters devised by Edison was based on the electrolytic principle. In the Edison meter a fraction of the current to be measured is passed through a zinc voltameter, consisting of two zinc plates in a solution of zinc sulphate, which is shunted by a German silver wire across the mains leading into the house. The passage of this fraction of current through the sulphate of zinc removes the zinc from one plate and puts it on the other, and from the measured gain in weight of the one plate or loss in weight of the other, the total electric quantity or time-integral of the current can be estimated. To keep the shunt ratio of the meter constant, Edison employed a copper coil, called a compensating coil, in series with the zinc voltameter, so adjusted that rise or fall in temperature altered its resistance as much in one direction as it altered that of the solution in the other. Another meter of the same kind now in use is the Long-Schattner prepayment meter. In this a certain fraction of the current supplied to any house or circuit is caused to pass through a solution of cupric sulphate contained in a copper box, in which hangs a copper plate suspended from a balanced arm, and as it passes, it removes copper from the suspended plate and deposits it upon the inner surface of the copper box. In this way the weight of the suspended plate is gradually diminished until, when a certain definite weight has been lost, the balance is destroyed and the arm flies up, breaking the main circuit by means of a mercury switch. When this has happened, the main circuit can be closed again by depositing in a slot of the meter a coin of a certain weight and value, say one shilling. The current then passes again, and again reduces the weight of the suspended plate, so that when an amount has been removed equal to the weight of the shilling, the balanced arm flies up and once more opens the main circuit. The whole apparatus is contained in a locked-up box, provided only with a slot and carrying tube for conveying a suitable coin into a bucket hung on the balanced arm. The meter can be so adjusted that the weight of the coin deposited provides the user of the meter with electric energy equal to the value of the coin. Thus the deposit of one shilling in the meter can be made to cause the circuit to remain closed until the customer has had say two Board of Trade units of electric energy; when that amount has been delivered, the supply is automatically cut off. The necessary calculations for designing the meter can be made from a knowledge of the electrochemical equivalent of copper, one ampere-hour of electric quantity passed through a solution of sulphate of copper removing from the anode 1.17700 grammes of copper.

Other quantity meters in use are those of Ferranti, Chamberlain and Hookham, Johnson and Phillips, and Schallenberger. The Ferranti continuous-current ampere-hour meter consists of an electromagnet, with its core formed of mild steel, having a certain retentivity for magnetism; this is worked at such a low flux density that its magnetization is always nearly proportional to the strength of the magnetizing current. In this core there is a disc-shaped cavity, which is lined with an insulating material and filled with mercury. The main current flows through the electromagnet coils, and, entering the mercury at the periphery of the disc-shaped cavity, flows inwardly radially in all directions to the centre of the mercury, whence it goes to the other terminal of the meter. Under these conditions the mass of mercury is set in rotation, but its motion is retarded by radial grooves formed in the sides of the chamber. The mechanical force driving it is proportional to the square of the strength of the current, and the force retarding it is proportional to the square of the speed; hence it follows that the number of rotations in any given time is proportional to the total quantity of electricity which has passed through the mercury. A little vane immersed in the mercury is used to register the rotations, the counting mechanism being so devised that the dials read off electric energy in Board of Trade units, on the assumption that the voltage of the circuit remains constant. The meter of Chamberlain and Hookham is of a very similar character, but the rotating portion consists of a copper disc fixed to a shaft, which carries another copper disc moving between the poles of an electromagnet. The first copper

¹ A joule is 10^7 ergs, and a British Board of Trade unit is 1000 watt-hours, or 3600 joules.

disc is immersed in a chamber filled with mercury, and the current to be measured passes radially through it from the circumference to the centre. Under the influence of the magnetic field which is created in a direction perpendicular to the plane of the disc, this disc is set in rotation; the associated disc is also rotating in the magnetic field, and is retarded by the so-called magnetic friction due to eddy currents set up in its mass. In these circumstances the speed of rotation of the two discs can be adjusted to be proportional to the current passing through the instrument, and hence the number of rotations in a given time is a measure of the electric quantity passed through the meter. Morley and Fricker have designed an ingenious meter of a very simple character. A slate disc has a number of soft iron wires inserted in it. This is attached to the escapement wheel of a clock which has no pendulum or hair-spring. The disc is included within a coil through which the current to be measured passes. When the current flows, it creates a magnetic field which pulls the iron wires into line with it, and owing to the inertia of the disc an oscillating motion is produced. The rate of going of the clock is therefore proportional to the current, and its registration to the electric quantity which has passed.

Intermittent Integrating Meters.—All the above forms of house meters are called continuously integrating meters, in that the operation of recording or obtaining the time-integral of the current or the power is continuous. There is, however, a large class of meters known as intermittent integrating meters, which consist of two parts. The first is simply an ammeter or a wattmeter, while the second is simply a clock, provided with a mechanism by which the deflection of the ammeter or wattmeter is recorded at regular time-intervals, and the records added up. A good example of such an instrument is that of Johnson and Phillips. This instrument comprises an electrically-driven clock, which operates a counting mechanism through a gearing whose ratio is controlled by the current passing into the circuit. The ammeter part of the instrument is a coil of wire, through which the current to be integrated passes, and into which a soft iron plunger is drawn down by the magnetic force. The degree to which this plunger is sucked in regulates the amount by which the clock mechanism advances the recording mechanism at each revolution; hence the number of revolutions of the counting dials in any time is proportional to the time and to the deflection of the ammeter needle—that is, to the total quantity of electricity which has passed through the meter.

Different opinions are held by electricians as to the relative advantages of quantity and energy meters. Generally speaking, quantity meters have the advantage of simplicity of construction; but energy meters must be employed if true electric power is to be measured on a circuit where the voltage is constantly fluctuating. Intermittent integrating meters are not suitable for use in cases in which the current is liable to suffer very large variations in strength enduring but a short time, as in the case of the electric supply to a theatre. The ampere-hour meters as a rule absorb less energy internally than the watt-hour meters. Watt-hour meters must, however, be employed if the supply is by alternating currents and the power-absorbing devices are inductive, such as electric motors.

Instruments for the measurement of electric resistance are called either *Bridges* or *Ohmmeters*. The simplest and most common form of resistance balance is that known as Wheatstone's bridge. As **Ohmmeters.** generally used in the laboratory, it consists of a box containing three sets of resistance coils; two of these sets are called the two ratio arms, while the third is the measuring arm. These coils are all joined up in series. In an ordinary form of Wheatstone's bridge, known as the series pattern plug-resistance bridge, there are a series of coils, two 1-ohm coils, two 10-ohm coils, two 100-ohm coils, and two 1000-ohm coils. These are joined up in series in the order 1000, 100, 10, 1; 1, 10, 100, 1000, and the junctions between each pair are connected to brass blocks, a series of which are mounted upon an ebonite slab that forms the top of the box. The blocks are bored out with a hole partly in one block and partly in the other, so that they can be connected by accurately-fitting conical plugs. When the blocks are interconnected by the plugs, all the coils are short-circuited; but if the plug or plugs are taken out, then a current flowing from one end of the series to the other is compelled to pass through the corresponding coils. In series with this set of coils is another set, the resistances of which are generally 1, 2, 3, 4, 10, 20, 30, 40, 100, 200, 300, 400, 1000, 2000,

3000, 4000 ohms. These form the measuring arm, and the junction between each pair of coils is connected as above described to a block, the blocks being interconnected by plugs. This series of coils is joined up with the resistance to be measured, and a galvanometer and a battery are added, as shown in Fig. 5.

This arrangement of six conductors joining four points is technically termed a Wheatstone's bridge arrangement. The values of the resistances forming the four arms of the bridge can then be so adjusted that if their values are called P, Q, R, and S, then when P : Q :: R : S a galvanometer circuit joined in between the junction of (P and Q) and (R and S) will not be traversed by any current when a battery is connected to a junction between (P and R) and (Q and S). To prove this statement, let the conductors P, Q, R, S, be arranged in a parallelogram form, and let B and G be the battery and the galvanometer circuit (Fig. 5), and let these letters stand for the resistances of these circuits respectively. Let E be the E.M.F. of the battery, and let (x+y) be the current along P, y that along Q, and z that along B, then by Kirchhoff's laws

$$\begin{aligned} (R+S+B)z - R(x+y) - Sy &= E, \\ (P+G+R)x + y - Gy - Rz &= 0, \\ (Q+G+S)y - G(x+y) - Sz &= 0. \end{aligned}$$

Rearranging the terms and solving for x, the current through the galvanometer, we obtain $x = E\delta/\Delta$ where $\delta = (QR - PS)$ and Δ is a function of P, Q, R, S, B, G, which does not concern us. Hence when P : Q = R : S we have $x = 0$, or the galvanometer current is zero.

An ordinary laboratory form of Wheatstone's bridge, as shown in Fig. 6, is known as the *dial pattern*. Ten brass blocks are

Fig. 6

arranged round a central brass block, and by means of a plug which fits into holes bored partly out of the central block and partly out of the surrounding blocks, any one of the latter can be connected with the central one. A series of nine equal resistances, say nine 1-ohm coils, or nine 10-ohm coils, or nine 100-ohm coils, are joined in between these circumferential blocks (Fig. 7). It

Fig. 7.

will be seen that if a plug is placed so as to connect any outside block with the central block, the current can only pass from the zero block to the central block by passing through a certain number of the resistance coils. Hence according to the magni-

tude of each coil the total resistance may be made anything from 1 to 9, 10 to 90, or 100 to 900 ohms, &c. Three or four of the "dials" thus composed are arranged side by side, the brass blocks being mounted on a slab of ebonite and the coils contained in the box underneath, and they are so joined up that the central block of one dial is connected to the outside block of the next marked O. This arrangement forms the measuring arm of the bridge, the ratio arms being constructed on the series plug pattern just described. A bridge of this pattern has the advantage that the insertion or removal of a plug in the measuring arm does not tend to tighten or loosen all the rest of the plugs; moreover, there are fewer plugs to manipulate, and each plug is always occupied. The resistance coils themselves are generally wound on brass or copper bobbins, with silk-covered manganin wire, which should first be aged by heating for about ten hours to a temperature of 140° C., to remove the slight tendency to change in resistivity which would otherwise present itself. For the accurate comparison of resistance coils it is usual to make use of the Matthiessen and Hockin bridge, and to employ the method of differential comparison due to Carey Foster.¹ On a board is stretched a uniform metallic wire (*a b*), generally of platinum silver. The ends of this wire are connected to copper blocks, which themselves are connected to a series of four resistance coils, A, B, and P, Q (Fig. 8).

Fig. 8.

A and B are the coils to be compared, P and Q are two other coils of convenient value. Over the stretched wire moves a contact-maker S, which makes contact with it at any desired point, the position of which can be ascertained by means of an underlying scale. A battery C of two or three cells is connected to the extremities of the slide wire, and the sensitive galvanometer G is connected in between the contact-maker and the junction between the coils P and Q. The observer begins by moving the slider until the galvanometer shows no current. The position of the coils A and B is then interchanged, and a fresh balance in position on the bridge is obtained. It is then easily shown that the difference between the resistance of the coils A and B is equal to the resistance of the length of the slide wire intercepted between the two places at which the balance was found in the two observations. Let the balance be supposed to be attained, and let *x* be the position of the slider on the wire, so that *x* and *l* - *x* are the two sections of the slide wire, then the relation between the resistances is

$$\frac{A + x}{B + l - x} = \frac{P}{Q}$$

Next, let the position of A and B be interchanged, and the slide-wire reading be *x*¹, then

$$\frac{B + x^1}{A + l - x^1} = \frac{P}{Q}$$

Hence it follows that *A* - *B* = *x* - *x*¹, or the difference of the resistances of the coils A and B is equal to the resistance of that length of the slide wire between the two points where balance is obtained.

Various plans have been suggested for effecting the rapid interchange of the two coils A and B; one of the most convenient was designed by J. A. Fleming in 1880, and has been since used by the British Association Committee on Electrical Units for making comparison between standard coils with great accuracy (see *Phil. Mag.*, Feb. 1880, and *Proc. Phys. Soc.*, Dec. 1879). In all very exact resistance measurements the chief difficulty, however, is not to determine the resistance of a coil, but to determine the temperature of the coil at the time when the resistance measurement is made. The difficulty is caused by the fact that the coil is heated by the current used to measure its resistance, which thus alters in value. In accurate comparisons, therefore, it is necessary that the coils to be compared should be immersed in melting ice, and that sufficient time should be allowed to elapse between the measurements for the heat generated in the coil to be removed.

The standard resistance coil employed as a means of comparison

by which to regulate and check other coils consists of a wire, generally of manganin or platinum silver, insulated with silk, and wound on a brass cylinder (Fig. 9). This is soldered to two

Fig. 9.

thick terminal rods of copper, and the coil is enclosed in a water-tight brass cylinder so that it can be placed in water, or preferably in paraffin oil, and brought to any required temperature. In the form of standard coil recommended by the Berlin Reichsanstalt the coil is immersed in an insulating oil which is kept stirred by means of a small electric motor during the time of making the measurement. The temperature of the oil can best be ascertained by means of a platinum resistance thermometer.

For the measurement of high resistance, such as the insulation resistance of house wiring, or of cables, we may employ either an ohmmeter or a direct method, in which the current sent through the insulation resistance by a large electromotive force is measured on a galvanometer. For example, if it is required to measure the insulation resistance of a length of cable such as is used for electric lighting purposes, the coil of cable, which should not be too short, is placed in a tank filled with water. Its copper conductors are then twisted together and connected to one terminal of a sensitive mirror galvanometer, whose other terminal is joined up with a battery of 200 to 300 secondary cells, which should be well insulated. The other terminal of the battery is connected to the tank. In these circumstances the battery will force a current through the insulating material with which the cable is covered, and this current will flow through the galvanometer. In order to prevent a leakage current also passing through the galvanometer, it is advisable to twist round the insulated conductor, at a short distance from the ends of the insulation nearest to the copper terminals, a fine wire, called a *guard wire*, which is connected to the junction between the battery and the galvanometer. Any leakage of current, therefore, taking place over the surface of the insulation will be conducted by the guard wire back to the battery, and prevented from passing through the galvanometer. In cable factories it is customary to employ a series of Leclanché cells varying from 100 to 1000 cells. The test is then made by applying the stated voltage to the conductor for a given time, generally one minute, and observing the current flowing through the galvanometer at the end of that time. Owing to the fact that the resistance of the dielectrics or insulators increases with the time of application of the electromotive force, it is necessary to state the time during which the electromotive force has been applied before the reading of the current is taken. With many dielectrics the resistance diminishes as the electromotive force is increased, even though applied in all cases for the same time. In the above measurement it is of course necessary that the galvanometer shall first be standardized; that is to say, we must discover the deflection produced by a known current. This is most easily done by sending through it a measured current, such as may be obtained by inserting in series with it a known high resistance, *e.g.*, a megohm, and applying a known electromotive force from a standard cell. For the details of these measurements standard treatises on electric measurement and testing must be consulted. In the ohmmeter of Evershed there are two coils at right angles, one of which is traversed by the current passing through the resistance to be measured, and the other by a current proportional to the fall of potential down that resistance. Hence a soft iron needle hung in the common field of the two coils will indicate by its direction the ratio of potential fall to current—in other words, the resistance of the conductor.

Many measurements peculiar to alternating currents have frequently to be made. One of the most important is the determination of the *wave form*. In the case

¹ "On a Modified Form of Wheatstone's Bridge, and Methods of Measuring Small Resistances," by Prof. G. Carey Foster, *Proc. Soc. Telegraph Engineers*, vol. i., May 1872.

of periodic electric currents, if the periodic time be supposed to be divided into an equal number of parts, which are represented by equal divisions on a straight line, and if the value of the current or the electromotive force at each of these instants is represented by the magnitude of a line drawn perpendicularly to the time line at the corresponding instant, then a curve drawn through the tops of all these perpendiculars will be a wave curve or periodic curve representing the wave form of the current. A very large number of devices have been invented for delineating this wave form. One of the oldest and simplest, due to Joubert, consists in attaching to the shaft of the alternating-current generator an insulating disc having inserted in its edge a metallic slip. This slip is touched by a pair of steel springs or brushes, with which it makes contact once every revolution. The brushes are carried on a rocking arm, which can be moved into any position round an axis concentric with the shaft of the alternator. The current from the generator is passed through a non-inductive resistance, across the terminals of which an electrostatic voltmeter is joined, the circuit, however, being interrupted by the above-described rotating contact-maker. The terminals of the voltmeter are short-circuited by a condenser. When the alternator is in operation, the contact-maker connects the voltmeter with the ends of the non-inductive resistance at regular intervals corresponding to some fixed point in the cycle. After a few revolutions the condenser becomes charged to a constant potential, and the voltmeter therefore indicates by its deflection this potential difference, which is the instantaneous potential difference of the extremities of the non-inductive resistance corresponding to a certain fixed point in the periodic time. By rocking over, the contact-maker springs into different angular positions, as indicated on a scale of degrees; and reading the corresponding deflection of the voltmeter, it is possible to plot out a curve which represents the variation of the volt fall down the non-inductive resistance, taken at equidistant intervals during the period. This, therefore, enables us to delineate the wave form of the alternating current. Numerous modifications of this point-by-point method have been devised by various experimentalists, but owing to its extreme tediousness the process has now been superseded by the use of an instrument called an *Oscillograph*.

This was originally invented by M. Blondel, but it has been improved by Duddell and others. In principle it is merely a dead-beat galvanometer having a needle or coil with a very small periodic time. Duddell's form consists of an electromagnet excited by a constant current which provides a steady strong magnetic field (Fig. 10), in which is stretched a pair of loops of fine wire, each consisting of a single half-turn in the shape of a hairpin. These two wires are at right angles to the direction of the field; and when a current passes, one of them is forced forward and the other backward, owing to the tendency of a conductor conveying a current to move across the lines of force of a field. To the wires is attached a small mirror of silvered glass, by means of which a ray of light from an electric arc lamp can be reflected upon another mirror and thence upon a screen. This second mirror is kept in vibration by a small alternating current motor so as to be in step with the alternating current under examination; if it were at rest, the light reflected from the first mirror, owing to its simple to-and-fro vibration, would, in consequence of the persistence of vision, appear as a straight line upon the screen. The displacement of the spot of light at its zero position at any instant is proportional to the strength of the current flowing at that instant through the oscillograph wires. If, then, the second mirror is set in vibration synchronously, the spot of light will be displaced in a direction at right angles, and the combination of the two motions will produce a wavy line of light, which is the optical representation of the wave form of the current. In order to secure dead-beatness, the mirrors vibrate in a chamber filled with transparent oil. In testing alternating currents which have a periodic time of about 100, it is necessary to employ an oscillograph having a mirror whose periodic time is anything between $1/2000$ th and $1/10,000$ th of a second. The oscillograph in its modern form is a very perfect instrument for the examination of alternating-current phenomena, since a very

large number of these effects are closely connected with the form of the wave of alternating current or electromotive force. Duddell

Fig. 10

has designed a form of portable oscillograph by means of which the wave form of any alternating current can be inspected by the eye.

The exact measurement of the mean power given to an inductive circuit by an alternating current is an important matter. In this case the mean power cannot be estimated simply by the product of the root-mean-square values of the current and terminal difference of potential, commonly called the *apparent watts* or *apparent power*. If the circuit is inductive, this quantity is always greater than the true watts or true power, and this ratio of the true watts to the apparent watts, or of the true power to the apparent power, is called the *power-factor* of the circuit. Hence special means are necessary for the measurement of alternating power. In the three-voltmeter method due to Ayrton and Sumpner this measurement is carried out in the following manner:—In series with the inductive circuit another non-inductive circuit is joined, and the two circuits are traversed by an alternating current. A suitable voltmeter, preferably electrostatic, is then employed to measure the volt fall down each of these two conductors separately, and down the two taken together. This may of course be done simultaneously by three separate voltmeters, but on account of the difficulty of obtaining three absolutely identical instru-

Three-voltmeter method.

ments, it is in every way preferable to employ one voltmeter, and to make the three measurements with it as quickly as possible one after the other, maintaining the current during the time perfectly constant.

If R is the resistance of the non-inductive resistance in ohms, and if V_1 , V_2 and V_3 are the voltmeter readings over the ends of the inductive, non-inductive, and total resistances, then the power in watts P absorbed in the inductive portion is

$$P = \frac{1}{2R} (V_3^2 - V_1^2 - V_2^2).$$

The three-voltmeter method involves, however, a possibility of producing a larger difference of potential than that which would be required to send the same current through the inductive resistance if it were employed alone. For instance, in measuring the power taken up in an alternating-current transformer worked say at 2000 volts pressure, in order to get accurate results it would be necessary to add in series a non-inductive resistance, and to employ a total electromotive force of about 4000 volts. It may not always be convenient to do this. Hence a modification was suggested by Fleming in which the current measurements are made either simultaneously with three ammeters or successively with one ammeter. The theory of the three-voltmeter method is as follows:—In the case of the three-voltmeter method let v_1 be the fall in potential down the inductive resistance, v_2 that down the non-inductive resistance, and v_3 that down the two together at any instant, then we have always

$$v_3 = v_1 + v_2 \therefore v_3^2 = v_1^2 + v_2^2 + 2v_1v_2.$$

Let R be the resistance of the non-inductive portion and i the current through it, then $iR = v_2$, and we have

$$v_3^2 = v_1^2 + v_2^2 + 2v_1iR,$$

or
$$iv_1 = \frac{1}{2R} (v_3^2 - v_1^2 - v_2^2).$$

Hence, taking root-mean-square values throughout a period and calling these V_1 , V_2 , V_3 , we have for the mean power P taken up in the inductive portion

$$P = \frac{1}{2R} (V_3^2 - V_1^2 - V_2^2).$$

As a general rule, by far the most convenient and accurate method of measuring alternating-current power is by

Transformer testing.

a suitable alternating-current wattmeter—an instrument constructed on the same lines as the Siemens dynamometer already described. One of the coils, say the fixed one, is traversed by the current which flows into the power-absorbing circuit; the other movable coil is traversed by a current which must be in step with the difference of potential at the extremities of the power-absorbing circuit. When the voltage employed to transmit the current through this circuit is at a high pressure, say 2000 volts or more, then the most convenient method of obtaining a current in step is to employ an alternating-current transformer, which must be of the closed magnetic circuit type, without magnetic leakage. If the primary circuit of this transformer is connected across the terminals of the power-absorbing circuit, then the electromotive force in the secondary circuit is exactly in opposition as regards phase with this difference of potential; hence if the movable coil of the wattmeter is practically non-inductive, and is joined in series with a non-inductive circuit and with the secondary circuit of the transformer (called the *Auxiliary Transformer*), then the current through the movable coil of the wattmeter is in step with the difference of potential between the ends of the power-absorbing circuit. Hence the reading of the wattmeter is proportional to the mean value of the product of the instantaneous values of the current through the power-absorbing circuit and the difference of potential between its ends—in other words, is proportional to the mean power taken up in that circuit. The wattmeter can best be standardized by employing it to measure the known power taken up in an inductionless circuit, such as a bank of incandescent lamps. The measurement of the power taken up in polyphase transformers or motors involves some special arrangements, but can be effected by the use

of two or three wattmeters. If the motor or transformer circuits are *star*-connected, the best plan is to employ three suitable alternating-current wattmeters simultaneously in each branch. If, however, they are *delta*-connected, then two wattmeters must be employed, with their series coils in two of the line wires and their shunts connected between these two and the third. If the power-absorbing circuit is inductive, then these two wattmeters will not give identical readings, and the real power taken up in the whole circuit is the sum or difference of their readings, according as the lag of current behind the voltage in each mesh circuit (assumed equal) is less or greater than 60° . The subject of power measurement in circuits of small power factor involves difficulties of a special kind, concerning which technical manuals must be consulted. For further information on the subject of transformer testing, see **TRANSFORMERS**.

See also the article **WEIGHTS AND MEASURES**. (J. A. F.)

Meath, a maritime county of Ireland, province of Leinster.

Population.—The area of the administrative county in 1900 was 577,743 acres, of which 114,812 were tillage, 414,837 pasture, 498 fallow, 9811 plantation, 8649 turf bog, 2369 marsh, 347 barren mountain, and 26,420 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, is identical with the old judicial county. The population in 1881 was 87,469; in 1891, 76,987; and in 1901, 67,463, of whom 34,717 were males and 32,746 females, divided as follows among the different religions:—Roman Catholics, 62,663; Protestant Episcopalians, 4359; Presbyterians, 323; Methodists, 61; and other denominations, 57. The decrease of population between 1881 and 1891 was 11·98 per cent., and between 1891 and 1901, 11·4 per cent. The average number of persons to an acre in 1891 was 13, and of the total population 70,597 persons inhabited the rural districts, being an average of 85 persons to each square mile under crops and pasture. The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr. Ep.	Presb.	Meth.
Read and write	26,350	25,103	51,453	72·0	91·9	96·3	98·5
Read only	3,529	3,655	7,184	10·8	3·5	1·6	
Illiterate	5,882	5,573	11,455	17·2	4·6	2·1	1·5

The percentage of illiterates among Roman Catholics in 1881 was 24·7. In 1891 there were four superior schools with 135 pupils (Roman Catholics 119, and Protestants 16), and 183 primary schools with 11,590 pupils (Roman Catholics 10,844, and Protestants 746). The number of pupils on the rolls of the National schools on 31st December 1900 was 12,091, of whom 11,424 were Roman Catholics and 667 Protestants.

The following table gives the number of births, deaths, and marriages in various years:—

Year.	Births.	Deaths.	Marriages.
1881	1355	1116	247
1891	1467	1407	238
1900	1259	1291	264

In 1900 the birth-rate per thousand was 18·7, and the death-rate 19·1; the rate of illegitimacy was 1·4 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 64,943, of whom 33,997 were males and 30,946 females. The chief towns in the county, with their populations in 1901, are—Navan, 3839; Kells, 2427; Trim, 1493.

Administration.—The county is divided into two parliamentary divisions—North and South—the number of registered electors in 1901 being respectively 5814 and 6284. The ratable value in 1900 was £550,529. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises three urban and eight rural sanitary districts.

Agriculture.—The following tables show the acreage under crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1901:—

Year.	Wheat.	Oats.	Barley, Rye, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Meadow and Clover.	Total.
1881	8119	32,099	2097	12,711	7048	3372	85,898	146,334
1891	1397	23,681	1184	10,941	5728	2843	78,984	124,758
1895	845	23,187	1034	10,380	5914	2680	77,395	121,083
1901	739	18,219	682	8,781	4989	2964	76,348	112,607

In 1900 the total value of the cereal and other crops was estimated at £634,306. The number of acres under pasture in 1881 was 386,374, in 1891, 405,912, and in 1900, 414,837.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	15,831	3174	173,841	156,099	13,730	5968	312,034
1891	17,714	2945	192,354	223,035	18,258	8887	350,549
1895	19,033	3236	201,089	177,178	15,216	7677	380,942
1901 ¹	16,046	3223	211,745	222,184	11,477	6958	404,538

The number of milch cows in 1891 was 15,431, and in 1901, 15,863. It is estimated that the total value of cattle, sheep, and pigs for 1901 was £3,345,709, the largest amount of any county in the province. In 1900 the number of holdings not exceeding 1 acre was 3008; between 1 and 5, 1774; between 5 and 15, 2512; between 15 and 30, 1874; between 30 and 50, 1192; between 50 and 100, 1220; between 100 and 200, 921; between 200 and 500, 555; and above 500, 89—total, 13,145. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts, 1885, 1891, and 1896, up to 31st March 1901 was 492, amounting to £345,533. The number of loans for agricultural improvements sanctioned under sect. 31 of the Land Act, 1881, between 1882 and 1901, was 304, and the amount issued was £38,752. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1901, was £213,470.

(W. H. Po.)

Meaux, chief town of arrondissement and railway station, department of Seine-et-Marne, 32 miles north-north-east of Melun. At its wool market some 200,000 fleeces are dealt in annually. A statue of General Raoult was erected in 1891. Population (1891), 11,350; (1901), 12,228.

Mechlin, or **MALINES**, a city of Belgium, on the Dyle, an important railway junction in the province of Antwerp, and the seat of an archbishopric. It lies in a level fertile plain, and is surrounded by promenades which have taken the place of the ancient ramparts. In contrast with other famous Flemish towns, Mechlin has no high towers, no grand buildings dominating the city, except the church belfries. In the 15th and 16th centuries the seat of important cloth manufactures, it has now for its principal branches of industry cabinet-making and carpentry, which employ 1200 workmen; chair-making, horticulture, and agriculture. It also contains extensive railway workshops of the State railways. Population (1875), 40,200; (1900), 55,705.

Mecklenburg, the common designation of two grand-duchies of the German empire, known as (i.) Mecklenburg-Schwerin and (ii.) Mecklenburg-Strelitz.

(i.) **MECKLENBURG-SCHWERIN** has an area of 5135 square miles, and population (1900), 607,835, giving a density of 118 inhabitants to the square mile. The population consisted of 300,419 males and 307,416 females. In 1895, 55.3 per cent. were rural and 44.7 per cent. urban; by religion nearly all the inhabitants are Protestant. The grand-duchy in 1895 embraced 97,069 farms, of which 65,531 were each less than 2½ acres in extent, 21,633 between 2½ and 25 acres, 8604 between 25 and 250 acres, and 1301 over 250 acres. The principal crops are potatoes, hay, wheat, oats, beetroot, rye, barley, and a little tobacco. The live stock in 1900 numbered 526,711 sheep, 452,635 pigs, 327,785 cattle, and 101,818 horses. The methods of farming have greatly improved since 1885. There is an agricultural experimental station at Rostock. In

¹ The figures for 1901 have not been revised.

1899–1900 the sugar factories of the two grand-duchies together produced 78,807 tons of sugar; the breweries, 10,494,000 gallons of beer; and the distilleries, 962,800 gallons (in 1897) of pure alcohol. The mercantile marine in 1900 numbered 65 sea-going vessels of 39,267 tons. Rostock, Warnemünde, and Wismar are the chief ports. There is a university at Rostock. The budget of the grand duke and estates together balanced in the year 1900–01 at £1,330,650. In 1900 the public debt amounted to £5,551,650; and in 1900 the state contribution to the imperial exchequer was fixed at £300,880. There were 730 miles of railway in 1900.

(ii.) **MECKLENBURG-STRELITZ** has an area of 1131 square miles, and population (1900), 102,628, of whom 50,870 were males and 51,758 females: density, 91 inhabitants to the square mile. With the exception of less than 1000, all the people belong to the Evangelical Lutheran Church. The number of farms in 1895 was 17,921, of which 13,844 were each less than 2½ acres in extent, 3846 between 2½ and 250 acres each, and 231 over 250 acres. The crops principally grown are potatoes, hay, wheat, rye, oats, beetroot, barley, and a little tobacco. In 1897 the live stock embraced 135,127 sheep, 61,598 pigs, 49,988 cattle, and 18,560 horses. The sugar, beer, and alcohol production are included in the returns for Mecklenburg-Schwerin. No statement of public revenue and expenditure is published; the state contribution to the imperial treasury was in 1900 fixed at £51,135; the public debt is estimated at £300,000. This duchy possessed only 154 miles of railway in 1900.

Medals. See **NUMISMATICS**.

Medellin, a city of the United States of Colombia, Central America, capital of the state of Antioquia, and also the seat of a bishopric. It is finely situated in a beautiful valley of a high plateau and on the Porce, a tributary of the Cauca, 150 miles north-west of Bogota. Founded as early as 1674, Medellin, after some centuries of comparative obscurity, has rapidly increased in wealth and importance, owing to the development of gold and silver mining, carried on mainly by British enterprise. While this has promoted a large general trade, many of the inhabitants are also employed in jewellery and other work in precious metals. The main hindrance to the growth of the city has been the lack of railway communication with the Magdalena river, only a small portion of the line from Puerto Berris being yet completed. The city possesses a university, a chemical laboratory, an elementary school, and other important educational institutions; also a mint, a theatre, a well-equipped hospital, and other public buildings. The streets are wide and regular, but badly paved. The principal exports are gold and silver, coffee, and hides. Population, about 50,000.

Medford, a city of Middlesex county, Massachusetts, U.S.A., on the Mystic river, 5 miles north of Boston, of which it is practically a suburb. It has large and varied manufactures, with (in 1900) a capital of \$1,328,106, and products valued at \$1,907,624. Tufts College, a Universalist institution, situated here, had, in 1899, 93 instructors, and was attended by 568 students, 148 of whom were women. Its property had a value of \$1,980,000, and its income was \$105,000. Population (1890), 11,079; (1900), 18,244, of whom 4327 were foreign-born and 244 were negroes.

Mediation, in the international sense, is the intervention of a third Power, on the invitation or with the consent of two other Powers, for the purpose of arranging differences between the latter without recourse to war. Mediation may also take place after war has broken out

with a view to putting an end to it on terms. In either case the mediating Power negotiates on behalf of the parties who invoke or accept its aid, but does not go further. Unlike an arbitrating Power, the mediator pronounces no decision, but limits his intervention to suggestion and advice. His action is liable to be arrested at any time at the will of either party unless otherwise agreed, in which last case to arrest it prematurely would be a breach of good faith. The difference between mediation and arbitration may be stated in the words of the Digest (lib. iv. tit. 8, § 13): "Recepisse autem arbitrium videtur, ut ait Pedius, qui iudicis partes suscepit finemque se sua sententia controversiis impositorum pollicetur. Quod si hactenus intervenit ut experiretur an concilio suo vel auctoritate disenti litem paterentur, non videtur arbitrium recepisse."

Some writers distinguish mediation from "good offices," but the distinction is of little practical value. We may, if we please, regard "good offices" as inchoate mediation, and "mediation" as good offices brought to the birth. Thus we may say that a third Power renders "good offices" when it brings the parties together so as to make diplomatic negotiations between them possible; whilst if it takes an active part in those negotiations it becomes for the time being a mediator, whatever the result of its intervention may be.

There have been many instances of successful mediation; e.g., of Great Britain, in 1825, between Portugal and Brazil; of France, in 1849-50, when differences arose between Great Britain and Greece; of the Great Powers, in 1868-69, when the relations of Greece and Turkey were strained to breaking-point by reason of the insurrection in Crete; of Pope Leo XIII., in 1885, between Germany and Spain in the matter of the Caroline Islands. In these cases mediation averted war, but it has been also resorted to for the purpose of putting an end to war already begun. The Austro-Prussian war of 1866, the war between Chile and Peru in 1882, and that between Greece and Turkey in 1897, not to mention other instances, were brought to a close through the mediation of neutral Powers. Mediation has also been occasionally employed where differences have arisen as to the interpretation of treaties or as to the mode in which they ought to be carried out, as when Great Britain mediated between France and the United States with regard to the treaty of Paris of 4th July 1830. In one case at least mediation has been successful after a proposal for arbitration had failed. In 1844, when war between Spain and Morocco was threatened by reason of the frequent raids by the inhabitants of Amalet el Rif on the neighbouring Spanish settlement of Ceuta, Spain declined arbitration on the ground that her rights were too clear for argument. But both she and Morocco subsequently accepted joint mediation at the hands of Great Britain and France.

The cause of mediation was considerably advanced by the Declaration of Paris of 1856. The plenipotentiaries of Great Britain, France, Austria, Russia, Sardinia, and Turkey then and there recorded in a protocol, at the instance of Lord Clarendon, their joint wish that "states between which any misunderstanding might arise should, before appealing to arms, have recourse so far as circumstances might allow (*en tant que les circonstances l'admettraient*) to the good offices of a friendly Power." Article 8 of the treaty of Paris, which was concluded in the same year, embodied this principle in a formal shape. The article stipulated that "if there should arise between the Sublime Porte and one or more of the other signing Powers any misunderstanding which might endanger the maintenance of their relations, the Porte and each of such Powers, before having recourse to the use of force, shall afford the

other contracting parties the opportunity of preventing such an extremity by means of mediation." These precedents (in which it will be seen that "good offices" and "mediation" are used interchangeably) were followed in the general Acts agreed to at the Conference held at Berlin in 1885 and 1890, the object of which was to secure religious and commercial liberty and to limit warlike operations in the regions watered by the Congo and its affluents.

The proviso above quoted, "so far as circumstances might allow," obviously leaves open a door of escape whenever two states in difference are bent on war. Accordingly, during the War of Secession between the northern and southern states of the American Union, offers of mediation, tendered by Russia in 1861 and by France in 1862, were courteously declined by Mr Seward. On the strength of the protocol of 1856, Great Britain made a similar offer both to France and Prussia in 1870 when war between these countries was imminent; but the emperor of the French replied that the same protocol expressly left discretion unfettered where the dignity of a nation was concerned. Again when, in 1877, Turkey appealed to her co-signatories of the treaty of Paris to mediate between her and Russia, her appeal was rejected on the ground that oppression of the Christian populations under her sway had led to so many revolts on their part as to menace the peace of Europe. In fact, nations on both sides of the Atlantic have hitherto shown no more disposition to permit questions they deem vital to be dealt with by mediation than to permit them to be dealt with by arbitration.

A special form of mediation was proposed by a delegate from the United States at the Peace Conference held at The Hague in 1899, and was approved by the representatives of the Powers there assembled. The clause in which this proposal was embodied provided in effect that, whenever there is danger of a rupture between two Powers, each of them shall choose a third Power to which these differences shall be referred, and that, pending such reference, for a period not exceeding thirty days (unless the time is extended by agreement) the Powers at issue shall cease to negotiate with each other and leave the dispute entirely in the hands of the mediating Powers. It will be seen that the Powers thus appealed to occupy a position analogous to that of seconds in a duel, who are authorized to arrange an "affair of honour" between their principals. This novel device has the advantage of toning down, if not of eliminating, personal and national prejudices by which controversy is frequently embittered. It also gets over the difficulty, so often met with in arbitration, of choosing a common referee who shall be satisfactory to both parties. The closer the relations between states become, the more their commercial interests are intertwined, the larger the part which mediation seems destined to play in the future. It is true that states which have accepted the intervention of a mediator remain free to adopt or reject any advice he may give, but the advice of a disinterested Power must always add considerable moral weight to the side towards which it inclines.

For authorities on the subject see ARBITRATION, INTERNATIONAL. (M. H. C.)

Mediatization.—The unification of Germany, which began with the formation of the Confederation of the Rhine (1806) and was continued by the treaty of Vienna (1815), entailed the "mediatization" (or deprivation of their sovereign power) of a number of princely houses, formerly "immediate" (*reichsunmittelbar*, i.e. holding directly of the emperor). To such were, however, reserved certain privileges and equality of personal rank with the princes of reigning houses: cf. *Encyc. Brit.* (9th edition), article GERMANY, vol. x. p. 492.

MEDICAL EDUCATION.

GREAT BRITAIN AND IRELAND.

UP to 1858 each University, Royal College of Physicians or of Surgeons, and Apothecaries' Hall in Great Britain and Ireland laid down its own regulations for study and examination, and granted its degree or licence without any State supervision. In that year, pursuant to the Medical Act, 21 and 22 Vict. c. 90, the General Medical Council of Medical Education and Registration was established, consisting of twenty-three members, of whom seventeen were appointed by the various licensing bodies and six by the Crown. This number was increased by the amended Act of 1886 to twenty-nine, three of the six additional members being elected by the profession as "direct" representatives. The object of the Act was "to enable persons requiring medical aid to distinguish qualified from unqualified practitioners." To this end the "Medical Register" was established, on which no person's name could be inscribed who did not hold a diploma or licence from one or more of the licensing bodies after examination. By the 1886 Act a qualifying examination was defined as "an examination in medicine, surgery, and midwifery," conducted by universities or by medical corporations, of which one must be capable of granting a diploma in medicine, and one in surgery. The powers of the Council over medical education consist in being authorized to require from the licensing bodies information as to courses of study and examinations, and generally as to the requisites for obtaining qualifications; and to visit and inspect examinations either personally or by deputy. If the visitors are of opinion that the course of study and examination of any licensing body is not sufficient to secure the possession by candidates obtaining its qualification of the requisite knowledge and skill for the efficient practice of their profession, on a report being made in these terms to the Council, the Council may represent the same to the Privy Council. Should the Privy Council be satisfied that the charge is substantial, it may, if it sees fit, deprive the accused body of its power to grant registrable qualifications. From this statement it will be seen that the powers of the Council are very limited; nevertheless, by their cautious application, and by the loyal manner in which the licensing bodies have acted on the recommendations and suggestions which have from time to time been made, the general condition of medical education has been materially improved; and although there is not a uniform standard of examination throughout the United Kingdom, the Council has succeeded in ensuring that the minimum requirements of any licensing body shall be sufficient for the production of trustworthy practitioners.

One of the first subjects the Council applied itself to was the establishment of a system of examinations in general knowledge. Such examinations have to be passed before commencement of medical study. On presentation of a certificate to the registrars of the Council, and on evidence being produced that the candidate is sixteen years of age, his name is inscribed on the "Students' Register." At present the subjects of examination are:—(a) English language, including grammar and composition (marks not exceeding 5 per cent. of the total obtainable in this section may be assigned to candidates who show a competent knowledge of shorthand); (b) Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors; (c) mathematics, comprising arithmetic;

algebra, as far as simple equations inclusive; geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions; (d) one of the following optional subjects—Greek, French, German, Italian, or any other modern language. Certificates are accepted from all the universities of Great Britain and Ireland, from the leading Indian and colonial universities, from Government examination boards, and from certain chartered bodies. The German Abiturienten-Examen of the gymnasia and *real-gymnasia*, the French diplomas of *Bachelier ès Lettres* and *Bachelier ès Sciences*, and corresponding entrance examinations to other Continental universities are also accepted. Whilst anxious to raise the general standard of preliminary examinations, the Council has not found it expedient to do so. In point of fact, the condition of secondary education in Great Britain and Ireland is so moderate in character as to render it inadvisable to set a higher minimum test, inasmuch as depletion of the profession might be produced to an extent detrimental to the public interest. On the other hand, it is right to state that only a moderate proportion of registered students pass on to the register on mere minimum requirements.

As regards professional education, the Council divided its resolutions into "requirements" and "recommendations"; the former consisting of demands on the licensing bodies, non-compliance with which renders them liable to be reported to the Privy Council as not conforming to conditions necessary to secure sufficient knowledge and skill for the efficient practice of medicine, surgery, and midwifery; the latter are regarded merely as suggestions for the general conduct of education and examination. The requirements may be summarized as follows:—(a) Registration as a medical student. (b) Five years of *bonâ fide* study between the date of registration and the date of the final examination for any diploma entitling the holder to be registered under the Medical Acts. (c) In every course of professional study and examinations the following subjects must be contained, the Council offering no opinion as to the manner in which they should be distributed or combined for the purposes of teaching or examination, this being left to the discretion of the bodies or of the student:—(i.) Physics, including the elementary mechanics of solids and fluids, and the rudiments of heat, light, and electricity; (ii.) chemistry, including the principles of the science, and the details which bear on the study of medicine; (iii.) elementary biology; (iv.) anatomy; (v.) physiology; (vi.) *materia medica* and pharmacy; (vii.) pathology; (viii.) therapeutics; (ix.) medicine, including medical anatomy and clinical medicine; (x.) surgery, including surgical anatomy and clinical surgery; (xi.) midwifery, including diseases peculiar to women and to new-born children; (xii.) theory and practice of vaccination; (xiii.) forensic medicine; (xiv.) hygiene; (xv.) mental disease. (d) The first of the four years must be passed at a school or schools of medicine recognized by any of the licensing bodies; provided that the first year may be passed at a university or teaching institution where the subjects of physics, chemistry, and biology are taught; and that graduates in arts or science of any university recognized by the Council, who shall have spent a year in the study of these subjects, and have passed in them, shall be held to have completed the first of the five years of medical study. (e) The study of midwifery practice must consist of three months' attendance on the indoor practice of a lying-in hospital, or the student must have been present at not less than twenty labours, five of which shall have been

conducted throughout under the direct supervision of a registered practitioner.

The fifth year of study is intended to be devoted to clinical work, and may be passed at any one or more public hospitals or dispensaries, British or foreign, recognized by the licensing authorities; six months of this year may be passed as a pupil to a practitioner possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities. This latter method of study is very rarely employed by students.

The "recommendations" of the Council contain suggestions which may or may not be acted on by the bodies. For the most part they are complied with in connexion with the system of practical and clinical teaching.

The Council satisfies itself that its requirements are acted on, and that the examinations are "sufficient," by cycles of inspection, which occur about every five years. The examination of each licensing body is visited by an inspector, who forwards his report to the Council, which sends each report to the body for its information and remarks. As yet it has never been the duty of the Council to report to the Privy Council that any examination has not been found sufficient. As a rule, suggestions have been accepted and acted on, and thus a high order of professional examination has been attained throughout the kingdom by gradual pressure.

Most of the universities exact attendance at more classes than the colleges and halls; for instance, botany and natural history are taught to their students, who are also examined in them. But with these exceptions the system of professional education is fairly uniform. Since 1875 attendance on "practical" classes has been called for in all subjects. Under this system the larger classes in which the subjects are taught systematically are broken up, and the students are taught the use of apparatus and the employment of methods of investigation and observation. Tutorial instruction is superimposed on teaching by lecture. Much the same plan is adopted in respect of clinical instruction: not only is the student taught at the bedside by the lecturer, but he receives, either from the house-surgeon or house-physician, or from a specially-appointed clinical tutor, an insight into methods of examination of diseases, and learns practically the use of the stethoscope and other aids to diagnosis, and of surgical and obstetrical instruments. In fact, it may be said that each subject of instruction is duplicated. If this is taken into account, it must be evident that the time of the student is fully occupied, and the belief is rapidly growing that five years is too short a period of study. As a matter of fact, the average time taken to obtain a British licence to practise is upwards of six years. The probability is that the solution of the difficulty will be found in the inclusion of such subjects as physics, biology, and chemistry in a "preliminary scientific" examination, which may have to be undertaken before registration as a medical student, thus leaving the whole five years to be devoted to purely professional study.

GERMANY.

The German regulations in regard to professional study are few. They are those for the *Staats Examen*, for which the university degree is no longer a preliminary requisite. The regulations for the admission of candidates to the *Staats Examen* are contained in the royal proclamations of 22nd June 1883. They comprise—(a) Certificate of a course of study at a classical gymnasium of the German empire. In exceptional cases, the same from a classical gymnasium outside the German empire may be considered sufficient. (For full details of the course of study and examinations, see *Minutes of the*

General Medical Council, vol. xxvii., Appendix 3.) (b) Certificate from a university, certifying a course of medical study of at least nine half-years at a university of the German empire. (c) Certificate that the candidate has passed, entirely at a German university, the medical *Vorprüfung*, and thereafter has attended for at least four half-years the medical studies of a university. (d) The special testimony of the clinical directors bearing witness that the candidate has taken part as *Praktikant* (clerk or dresser) during two half-years at the medical, surgical, and gynæcological clinics; has himself delivered two cases of labour in the presence of his teachers or assistant physicians; and has attended for a half-year as *Praktikant* the clinic for diseases of the eye. The medical *Vorprüfung* referred to is necessary alike for the *Staats Examen* and the degree of Doctor of Medicine. It takes place at the end of the second year (fourth semester), and includes the subjects of experimental physics, chemistry, botany, zoology, anatomy, and physiology. It is conducted by a board appointed yearly by the Minister of Education.

FRANCE.

No one can practise medicine in France who does not possess the diploma of Doctor of Medicine of a French university. The qualification of *Officier de santé* is no longer granted. Before he can inscribe as a student of medicine the applicant must have obtained the diploma of *Bachelier ès Lettres*, and the diploma of *Bachelier ès Sciences*. Although the course of professional study may be completed in four years, a longer time is generally taken before the student proceeds to the final examination for the doctor's degree. Each year is divided into four trimestres; at each trimestre the student must make a new inscription. The trimestres are (1) November and December, 56 days; (2) January, February, March, 86 days; (3) April, May, June, 86 days; (4) July, August, 56 days. Practically there are no regulations determining the division of the various subjects, or the number of lectures in each course, or requiring the student to attend the courses. The medical faculty of each university puts before the student a scheme recommending a certain order of studies (*Division des études*) for each of the four years of the medical course, and, as a matter of fact, this order of study is enforced by the system of intermediate examinations (*Examens du fin d'année*). All the lecture courses are free, as also are the clinics and the hospital service, and there is no system of ascertaining the regularity of attendance at lectures, or of certificate of attendance. If, however, the student fails to pass the *Examen du fin d'année* he is debarred from making the next trimestral inscription, and thus loses three months. The lectures are, however, closely attended. In contrast to the freedom in regard to attendance on systematic lectures, there are strict direction and control in regard to hospital attendance and practical courses. The student is required to sign a register *ad hoc* each time he goes in and out. From the beginning of the third year, e.g., from the ninth quarterly inscription, hospital attendance is enforced till the end of the fourth year. No one can renew his trimestral inscription without producing a schedule of his last trimestral stage, showing that during it he had not absented himself more than five times without explanation. Practical work is obligatory during each of the four years. Besides systematic course of lectures, *Conférences* are held by the assistant-professors (*Agrégés*) in natural history, physiology, general pathology, internal pathology, external pathology. At the end of the first year the student is examined in physics, chemistry, natural history, osteology, myology, and the elements of physiology; at the end of

the second year, in anatomy and physiology in all their branches; at the end of the third year, in medicine and surgery; at the end of the fourth year, an examination is held over the whole field of study.

DENMARK.

No one is allowed to enter on the study of medicine without passing the *Artium Examen* of a secondary school. This is the equivalent of the German Abiturienten-Examen of a classical gymnasium. After study for two *semestres* an examination must be passed in psychology, logic, and history. The special professional examinations consist of (1) preliminary scientific, in botany, zoology, physics, chemistry; (2) first special or professional, anatomy (orally and by dissections), physiology, and pharmacology; (3) second special or professional, written examinations in medicine, surgery, medical jurisprudence; practical and oral in operative surgery, in clinical medicine, and clinical surgery; and oral in pathological anatomy, medicine, surgery, and midwifery.

AUTHORITIES.—The history of the development of medical education from the earliest times down to 1894 will be found treated of generally in PUSCHMANN'S *Geschichte des medicinischen Unterrichts* (Leipzig, 1889), translated by E. H. HARE (London, 1891). Those desiring more special information on the subject in regard to the details of British institutions should consult the annals of the various universities and colleges of Great Britain and Ireland. The following works supply much interesting information regarding the gradual rise and development of teaching and examination:—*Annals of the Barber Surgeons*, by SYDNEY YOUNG, 1890.—*History of the Royal College of Surgeons of Ireland*, by CAMERON, 1886.—*Early Days of the Royal College of Physicians of Edinburgh*, by PEEL RITCHIE, 1899.—*Historical Sketch of the Royal College of Surgeons of Edinburgh*, by GAIRDNER, 1860.—*Memorials of the Faculty of Physicians and Surgeons of Glasgow*, by DUNCAN, 1896.—*The Story of the University of Edinburgh*, by Sir A. GRANT, 1884.—*University of Glasgow*, by STEWART, 1891. (J. B. T.)

UNITED STATES.

In 1870 and even in 1880 medical education in the United States was in a deplorable condition. In the early history of the country, before and shortly after the beginning of the 19th century, the few medical colleges that were in existence had shown a disposition to require a liberal education on the part of those who entered upon their courses, and some effort also was made, through the agency of state boards, to control the licence to practise. But as the country increased in population and wealth, so far from this good beginning being followed out, preliminary requirements were practically abolished, the length of the courses given each year was shortened to four or five months or less, and in the second and final year there was simply a repetition of the courses given during the first year. This unfortunate condition of affairs is to be attributed mainly to the fact that there was no general national or state supervision of medical training. Medical colleges could obtain incorporation under state laws without difficulty, and brought considerable advantages in the way of prestige and increased practice to those concerned. That the existence of a college depended solely upon the fees of the students encouraged the tendency to make both entrance and graduation requirements as easy as possible, especially as there was no state supervision, and the mere possession of a diploma entitled the holder to practise. Fortunately, during this period the practical character of the clinical instruction given in the better colleges fitted the graduates in some measure for the actual necessities of practice, while the good traditions of medicine as a learned profession exerted a stimulating influence upon those who adopted it as a career, so that in the main the body of practitioners deserved and held the confidence and respect of the community. From the middle of the

19th century to the present time there has been a constant agitation on the part of the physicians themselves for an improvement in medical education. The first notable result of this agitation was an increase in the time of instruction from two to three years (Chicago Medical College, 1859; Harvard Medical School, 1871), the lengthening of each session to six months or more, and the introduction of graded courses instead of a repetition of the same lectures every year. The improvement thus begun became very marked during the decade 1890-1900, amounting in fact almost to a revolution in the rapidity with which the course of instruction was amplified. Many factors co-operated to produce this desirable result: general development of scientific instruction in the colleges and secondary schools, the influence of the large number of medical graduates who completed their training by study in European schools, the adoption by many states of stringent regulations regarding the licence to practise within their borders, the good examples set by many leading schools in voluntarily raising their requirements for entrance and graduation, and, perhaps above all in its general effect, the agitation continually maintained by several national or state associations which in a measure have exerted the general regulating control that in other countries has been enforced by national legislation. Among the most influential of these associations are the American Medical Association, the American Academy of Medicine, the Association of American Medical Colleges, the Illinois State Board of Health, and the University of the State of New York.

The conditions at present are improving rapidly, but are difficult to describe except in general terms, as the requirements for matriculation and graduation vary greatly in the different states of the Union, and the arrangement of the courses follows no uniform plan. There are 166 medical schools in the United States, of which 10 are graduate schools. Of these, 122 are classed as so-called regular schools, 21 as homœopathic, 7 as eclectic, and 3 as physio-medical. In 1885 out of the 102 existing schools, only 5 offered a course of three years. In 1897, 99 schools required a course of four years, while in 1899, 141 of the 156 undergraduate schools announced a course of four years as necessary to graduation. There is a gratifying tendency also to increase the standard of preliminary requirements for entrance to the medical schools. The colleges comprising the Association of American Medical Colleges, 82 in number, have agreed upon uniform entrance requirements that are practically equivalent to the completion of one year's study in a high school. In New York and Illinois there is a uniform minimal requirement equivalent to the completion of a high-school course of four years, and other states have announced that a similar requirement will be made in the future. The Johns Hopkins Medical School from its foundation in 1893 has admitted as students only those who are graduates of a recognized college, and has required, moreover, that the candidate shall possess a reading knowledge of French and German, and have had a year's training in physics, chemistry, and biology. The Harvard Medical School since 1901 has also required a degree in arts, sciences, literature, or philosophy as a condition for entrance, while the Rush Medical College (University of Chicago) and the medical departments of the University of Michigan and the University of California have announced entrance requirements that will practically demand two years of collegiate work. Following the initiative of the Johns Hopkins, these schools have specified that the preliminary training must include courses in physics, chemistry, biology, French, and German. The

medical department of the Western Reserve University (Cleveland) requires certificates showing the completion of at least three years in a recognized college. The good examples set by these and other schools will doubtless result soon in a general increase in entrance requirements to the point that those entering upon the study of medicine must give evidence of a preliminary training equivalent at least to that required for matriculation in a college of good standing.

In regard to the medical curriculum itself there has been of late years much dissatisfaction, directed, it may be said, not so much towards the contents of the curriculum as towards the methods of instruction. The relative merits and demerits of the laboratory and the lecture system are being constantly debated, and such discussion, together with the practical trials of the two systems, will doubtless eventually lead to a substantial improvement in the character of medical instruction. As an outcome of this agitation the following general tendencies may be noted. A large number of the best medical colleges have entered into close affiliation with the leading universities, and there seems to be a distinct appreciation of the value of this organic union with institutions devoted to the higher learning. In a number of cases this affiliation has led to the development of what are known as combined courses, by means of which the total time required for obtaining both the collegiate and the professional degree is reduced by one or two years. The reduction is made possible by the acceptance on the part of the college faculty of the scientific work done in the first year or two of the medical course as fulfilling part of the requirements for the baccalaureate degree. There can be no doubt that this recognition of the scientific instruction in the medical schools is not only a testimonial to its thoroughness, but amounts to a guarantee that this work will be committed to the care of trained and capable specialists. It is probable, in fact, that in some instances the experiment will be made of leaving the instruction in the preparatory medical sciences entirely in the hands of the college faculty.

Some of the medical schools are making an effort to break away from the rigid system of graded courses that prevails generally, and instead to offer various alternative studies, particularly in the third and fourth years, adapted to meet the needs and stimulate the interests of individual students. In general, however, it may be said that the system of instruction for the required four years of medical study tends to follow the general lines laid down by Huxley in his well-known address upon "Universities, Actual and Ideal" (1874)—that is, the first two years are given up to the study, largely by laboratory methods, of what may be called the preparatory sciences, while in the last two years attention is directed mainly to practical instruction in the science and art of medicine in the hospital, the clinic, and the dispensary.

Medical Jurisprudence, or FORENSIC MEDICINE, is the science which deals with the application of medicine to certain questions of civil and criminal law, for the determination of which evidence derived from medical experience is required. During recent years no fundamental changes have been made in its principles as laid down in the older books upon the subject, but close observation, fresh experience, and more modern methods of investigation have thrown new light upon various branches, and have thus tended to place the whole subject upon a more scientific basis than formerly. The present article is confined to supplementing the topics dealt with in the ninth edition of the *Encyclopædia* under this heading and that of POISONS.

I. *The Signs of Death.*—The determination of the actual existence of death assumes a certain importance in tropical countries, where the necessity for speedy interment may involve a risk of burial alive. Such an accident cannot well occur where a medical man confirms the existence of death, and in the United Kingdom, where burial rarely takes place before the lapse of forty-eight hours, such changes usually occur in the body as to render any error practically impossible. Within a varying period, usually not more than twelve hours, the body becomes rigid, owing to the development of *rigor mortis* or *post-mortem* rigidity. The blood, which during life is equally distributed throughout the body, gravitates to the most dependent parts and develops a discoloration of the skin which is known as *post-mortem* lividity or *post-mortem* staining. At a variable period of time, dependent on the cause of death, also the temperature and moisture of the air to which the body is exposed, decomposition or putrefaction sets in. These changes which a body undergoes after death are of great importance, not only as affording certain proof of death, but also because they furnish valuable information as to the probable time at which it occurred, and from the fact that they may alter or destroy evidence as to the cause of death.

II. *Identity.*—In the case of the living, identification is rather a matter for the police officer than for the medical man. Bertillon and Galton have each devised methods for the identification of criminals which are much more certain than those formerly relied on (see also ANTHROPOMETRY). Bertillon's system consists in taking certain anthropometrical measurements of the cranium and face, and recording other general characteristics. Galton's method consists in taking impressions of the skin markings of the thumb and fingers, which give definite and distinctive patterns for each individual, so that by means of a proper system of classification it is possible to identify an individual within a few minutes. This system is largely used in India. Medical evidence may, however, be necessary to decide a question of identity in the living, as in the Tichborne case, where the deletion of tattoo marks, or the existence of scars, had to be determined. In the dead, identification is effected by means of clothes, bodily characteristics or peculiarities, photography, &c., or the body itself may be preserved for identification by keeping it at a low temperature, as in the Morgue at Paris.

III. *Injuries or Wounds.*—These include in a medico-legal sense not only those characterized as incised, punctured, contused, lacerated, stab wounds, but also burns, injuries produced by firearms, fractures, dislocations, &c. One of the chief questions which have to be decided in all forms of violent death is whether it was the result of accident, suicide, or murder. In cases of fatal wounding, among the points to be noted, which will help to decide the question, are the situation, direction, and extent of the wound, the position in which the body

and any weapon may be found, together with the presence and distribution of any blood marks and the signs of a struggle. In wounds caused by firearms the injury, if suicidal, is usually situated in a vital and accessible part of the body, the temple, mouth, and chest being the favourite situations; but such an injury also presents, as a rule, the characteristic appearances resulting from the discharge of the weapon close to the body, viz., besides the wound of entrance of the bullet, there is singeing of the cuticle and hair, and blackening of the area immediately surrounding the wound, from particles of unconsumed powder being driven into the skin and from the smoke of the discharge. These effects are naturally not produced when the weapon is discharged at a distance exceeding 2 or 3 feet, as usually happens in cases of homicidal shooting. They may also be wanting in undoubted suicidal wounds produced by revolvers and cartridges filled with amberite or other smokeless powders. Death from burning is generally accidental, very rarely suicidal, and when homicidal, is usually employed to conceal traces of other violence inflicted upon the body. In large conflagrations death is not always due to burning. Charred bodies may be found presenting various injuries due to the fall of beams, crushing, the trampling of others trying to escape, &c., or fractures and lacerations may be due simply to the action of the heat. Death may result from such injuries, or from suffocation by the gases of combustion, before the victim is affected by the actual fire. Spontaneous combustion of the body has been stated to occur, but the evidence upon which the cases rest is not well authenticated.

IV. *Death from Asphyxia*.—Amongst the forms of violent death due to this cause are drowning, hanging, strangulation, garotting, smothering, suffocation from choking, mechanical interference with the expansion of the chest walls, as when persons are crushed together during a panic in a fire, breathing poisonous gases, such as carbonic acid or carbonic oxide. In connexion with the last form of death, which in the United Kingdom usually results accidentally from an escape of lighting gas, the danger has been much increased in many towns owing to the addition of carburetted water-gas to the ordinary supply. Carbonic oxide gas is contained in ordinary lighting gas to the extent of about 6 to 8 per cent., and is extremely fatal when inhaled. Carburetted water-gas contains about 28 per cent., and when mixed with ordinary lighting gas the percentage of carbonic oxide is thus very much increased.

V. *Criminal Abortion*.—This crime consists in unlawfully procuring the expulsion of the contents of the gravid uterus at any period short of full term. It must be noted that while this definition may be held to recognize the induction of premature labour by medical men in certain circumstances, yet, when the operation is necessary, a medical man should always protect himself from possible misconstruction of his action (*i.e.*, criminal intent) by having a consultation with another practitioner. The means employed in criminal abortion to procure the desired result may be classed under three heads: (1) general violence to the body, (2) administration of drugs supposed to have abortifacient qualities, (3) instrumental interference with the contents of the womb. Amongst the drugs frequently employed for the purpose, although by no means always successfully, are ergot, strong purgatives, iron, rue, pennyroyal, savin.

VI. *Infanticide*.—The killing of a recently-born infant which has been "born alive," *i.e.*, has lived after being completely born, is termed infanticide, and the crime amounts to murder. The Crown takes upon itself the *onus* of proving in every case that the child has been

born alive. This is often a matter of difficulty, and hence an alternative charge of concealment of birth in England, or concealment of pregnancy in Scotland, is usually preferred in such cases, and, if proved, may entail a penalty of two years' imprisonment. The chief medical questions to be determined from an examination of the body of an infant in connexion with a charge of infanticide are: (1) as to its maturity, (2) whether it has breathed or not, (3) whether it was "born alive," (4) how long it survived its birth, (5) what was the cause of death. The proof of respiration having taken place is of prime importance, although it does not necessarily follow when a positive result is obtained that the child was "born alive." The fact of the lungs having respired is determined by their appearance and consistence, and by the hydrostatic test, which depends upon the difference in the specific gravity of the lungs before and after the entrance of air into them through respiration.

VII. *Rape* consists in the carnal knowledge of a woman by force and against her will. It is rape if the crime be perpetrated with consent obtained by a fraud, such as the impersonation of a woman's husband, or by producing mortal terror. Since the passing of the Criminal Law Amendment Act, 1885, it is a felony, entailing the same punishment as rape, to have carnal knowledge of a girl under thirteen years, whether she consent or not. Between thirteen and sixteen years of age it is a criminal offence punishable by two years' imprisonment, whether consent is given or not, and even if there be solicitation. Above sixteen years of age no offence is committed, if consent be given, provided the woman is not an idiot or an imbecile. The administration of any drug or matter, with intent, by producing stupor, to facilitate the accomplishment of the crime, is an offence punishable by two years' imprisonment. In all charges of rape, the woman and her assailant should be examined as soon as possible by a medical man, but such examination, it is important to remember, can only be carried out with the free consent of the party to be examined.

VIII. *Blood Stains*.—The examination of blood stains is a frequent and important operation in criminal charges. Blood stains when fresh and abundant can be recognized without difficulty, but when old, or after being acted upon by certain substances, their identity is not readily determined. The tests which may be applied to a suspected stain consist of:—(1) *The microscopic test*. A portion of the stain is soaked in a drop of some fluid which will soften and cause separation of the dried blood corpuscles without altering their characteristic appearance. Such fluids are solutions of glycerine and water of a specific gravity of 1028, or 30 per cent. caustic potash. The recognition of blood corpuscles affords evidence of the nature of the stain. (2) *Chemical tests*. (a) Heat applied to a solution obtained by soaking some of the stained fabric in cold water. A blood solution is red, and loses its red colour on application of heat, while at the same time a buff-coloured precipitate is formed. (b) On applying a drop of freshly prepared tincture of guaiacum and then some ozonic ether or peroxide of hydrogen to the stain, a blue colour is obtained if blood be present. Many other substances, however, give the same reaction. (c) If, even to the smallest particle of dried blood, a fragment of common salt and some glacial acetic acid be added, and the latter is then heated to ebullition and allowed to evaporate away, small brown rhomboid crystals—hæmin crystals—will be found to have formed, and they can be recognized under the microscope. (3) *Spectroscopic test*. A solution of blood obtained from a stain will show a spectrum having two dark bands between Fraunhofer's lines D and E (oxyhæmoglobin). On adding ammonium sulphide to the

solution the hæmoglobin is reduced and only one broad dark band is seen (reduced hæmoglobin). On adding caustic potash to a solution of blood, alkaline hæmatin is formed, and this again is transformed on the further addition of ammonium sulphide into reduced hæmatin or hæmochromogen, which gives a very characteristic spectrum of two dark bands situated in the yellow part of the spectrum. The production of these three different spectra from a red-coloured solution is characteristic of blood. Old blood stains are insoluble in water, whereas recent stains are readily soluble in cold water, yielding a red solution. The application of hot water or washing with soap tends to fix or render blood stains insoluble. Vegetable dyes may likewise give red solutions, but they may be distinguished from blood by the addition of ammonia, which alters the colour of the former, but rather intensifies the red colour of a blood solution. The differentiation between human blood stains and those produced by the blood of other animals, more especially domestic animals, is a matter of great importance to the medical jurist. When the blood stain is fresh, measurement of the corpuscles may decide the question, but in the case of dry and old stains it is impossible to make the distinction. A method has been discovered, however, which enables the distinction to be made not only between human blood and that of other animals (with the exception of *Simiidae*), but also between the bloods of different animals. The method depends upon the fact that if an animal (A), such as a dog or rabbit, is inoculated with the blood or serum of another animal (B), then the blood or serum of A is found to produce a specific reaction (namely, the production of a cloudiness or precipitate) when added to a solution of the blood of a similar animal to B, and that species of animal only. If, therefore, human blood serum is injected into an animal, its blood after a time affords an "anti-serum" which produces the specific reaction only in human blood solutions and not in those formed from the blood of other animals.

IX. Poisoning.—There is no exact definition of a poison. Popularly, substances which destroy or endanger life when swallowed in small quantity are called poisons, but a scientific definition would also include many substances which are injurious to health in large doses or only after repeated administration, and which act not only when swallowed, but also when taken into the system through other channels, *e.g.*, the skin or the lungs. The branch of science which relates to poisons, their nature, methods of detection, the symptoms produced by them, and treatment of poisoning, is called Toxicology, and is one of the most important subjects included under the term Medical Jurisprudence.

Poisons may be classified according to their effect upon the system. Those poisons which produce local action upon the tissues with which they come in contact, corroding or destroying them, are known under the name *Corrosive Poisons*; such are the concentrated mineral acids, sulphuric, nitric, and hydrochloric, the alkalis, potash, soda, and ammonia, and their carbonates, corrosive sublimate, butter of antimony, carbolic acid, and oxalic acid. Some of these, in addition to a local action, produce toxic symptoms due to a remote action upon other organs, the result of their absorption into the blood. Among the latter may be mentioned carbolic acid, which not only corrodes the tissues with which it comes in contact, but also causes rapid unconsciousness and death due to respiratory and cardiac paralysis. Poisoning by this substance, which is usually accidental or suicidal, rarely homicidal, has become very frequent, a rapid and progressive increase in deaths from it being observable year by year. In England and Wales from 1888 to 1897 it caused the deaths

of 547 males and 584 females from suicide and 190 males and 130 females from accident or negligence. The total number of deaths in ten years thus amounted to 1451. The chief cause of the increasing frequency of deaths from this cause is to be traced to its common use as a household disinfectant. Some poisons, again, may be classed as *Irritants*, because one of their chief symptoms and effects on being swallowed is irritation of the stomach and intestines. In this class are included various metals and their salts, *e.g.*, arsenic, antimony, lead, and copper; non-metallic elements, *e.g.*, phosphorus; a large number of vegetable substances, *e.g.*, castor-oil, colocynth, elaterium, &c.; and some animal substances, *e.g.*, cantharides. In another class of poisons there is little or no local action, the symptoms produced being chiefly referable to an action on the brain and spinal cord; such poisons have been called *Neurotics*. Examples of this class are to be found in opium, prussic acid, belladonna, strychnine, and aconite. A few poisons may be further classified as *Gaseous*, since they act while in a vaporous condition, some producing a local irritant action upon the lining membrane of the air passages, *e.g.*, ammonia and chlorine; others, again, being absorbed through the lungs into the blood and producing their poisonous effects in this way, *e.g.*, chloroform, sulphuretted hydrogen.

The medical evidence in cases of poisoning rests upon—(1) the symptoms produced during life; (2) the *post-mortem* appearances; (3) the chemical analysis and detection of the substance in the body, or in the excretions and vomited matters, or in articles of food; (4) experiments on animals in the case of certain poisons where other conclusive evidence is difficult to obtain. The treatment of cases of poisoning will vary according to the substance taken, but the general principles which should be followed are: (a) to get rid of the poison by means of the stomach pump, or by washing out the stomach with water through a soft rubber tube, or by giving an emetic such as mustard, sulphate of zinc, ipecacuanha; (b) to neutralize the poison by giving a substance which will form with it an innocuous compound (*e.g.*, in the case of the strong acids by administering magnesia or common whiting), or which has an opposite physiological action (*e.g.*, atropine in opium poisoning); (c) to promote the elimination from the body of the poison which has been already absorbed; (d) general treatment of any dangerous symptoms which appear, as by stimulation in collapse or artificial respiration in asphyxia.

Many plants owe their poisonous properties to the presence in them of basic bodies called *alkaloids*, which are mostly solid, crystalline, and non-volatile, only a few (*e.g.*, conine and nicotine) being liquid and volatile. They are generally active poisons in minute doses, and the proof of their administration in criminal cases is surrounded with special difficulty, owing to the fact that they produce no very characteristic symptoms or marked changes in the body, while the chemical detection of the poison in the tissues is by no means easy or always successful. Amongst the many well-known alkaloids may be mentioned morphine, obtained from opium, strychnine and brucine from *nux vomica*, atropine from belladonna, cocaine from *Erythroxylon coca*, nicotine from tobacco, conine from the spotted hemlock. The power of manufacturing alkaloids is not confined to plants; they are also formed in the living body as a result of physiological processes, and in dead bodies as a result of the action of putrefactive bacteria. It is mainly owing to the investigations of Selmi and of Brieger that our knowledge of these animal alkaloids or *ptomaines* has assumed definite shape. The discovery that they may be formed in the body after death by the action of putrefactive bacteria was at first thought to be a great obstacle to the proof of criminal poisoning

by means of vegetable alkaloids, but investigation has shown that this is not so, since it is found that, although many ptomaines are formed after death, yet practically very few possess active poisonous properties, *e.g.*, neurin and mydalein, and these do not appear until a considerable time after death, and then only in minute quantities. In addition, ptomaines do not respond to all the various tests and reactions which are characteristic of vegetable alkaloids.

Food Poisoning (see also ADULTERATION).—Foods may prove noxious from a variety of causes:—(1) The presence of metallic poisons, as in peas artificially coloured with copper salts, in tinned foods from dissolved tin salts, &c. (2) The contamination of any food with the specific germs of disease, as for example milk infected with the germ of enteric fever. (3) The presence in meat of parasites, such as the *Trichina spiralis*, or of disease in animals, capable of transmission to man, such as tuberculosis, or the presence of poison in the flesh of animals which have fed on substances harmless to them but poisonous to human beings. Grain may be infected with parasitic fungi of a poisonous character, as for example *Claviceps purpurea*, causing epidemics of ergotism. (4) Foods of various kinds may contain saprophytic bacteria which elaborate certain poisons, either before or after the food is taken. It is chiefly in relation to food poisoning from the last-mentioned cause that our knowledge has been increased in recent years.

Many cases of food poisoning, previously of mysterious origin, can now be explained by the action of bacteria and the products which they give rise to—tox-albumoses, ptomaines, toxins—by splitting up proteid substances. It is not necessary that the food should show evident signs of putrefaction. It may not do so, and yet on being eaten produce violent symptoms of gastro-intestinal irritation almost immediately, followed by various nervous symptoms. In such cases a chemical poison, developed by putrefactive bacteria before the food was eaten, quickly acts upon the system. On the other hand, symptoms may not appear for many hours after ingestion of the food, and then come on suddenly and with great severity—there has been a period of incubation. In such cases the food when swallowed has contained the bacteria, but the poisonous toxin has been elaborated by them afterwards in the system during the period preceding the onset of symptoms. In both varieties of poisoning the symptoms are similar, consisting of gastrointestinal irritation—vomiting, purging, and pain in the abdomen—together with great prostration, fever, muscular twitchings, disturbances of vision, delirium, and coma. The varieties of meat which have most frequently given rise to poisoning (*Botulismus*) are pork, ham, veal, sausages, brawn, various kinds of meat pies, and potted meats. Pig flesh appears to be specially liable to become infected. A point of considerable interest, which has sometimes given rise to doubt as to the poisonous character of meat in certain instances, is, that the same food may be poisonous at one time and not at another. Thus it may be harmless when freshly prepared, cause fatal effects if eaten a day or two afterwards, and shortly after that again prove perfectly innocuous. This is explained by the fact that the toxic substances take some time to develop, and after development are still further split up by the bacteria into other bodies of a harmless nature.

In some fish, *e.g.*, *Trachinus draco* or sea weaver, the poison is a physiological product of certain glands. In others the poison is not known, as in the family *Scombridae*, to which the disease Kakkè has been attributed. In the United Kingdom the poisonous effects produced by fish are due to bacterial agency after death, and instances have

occurred from the eating of herrings, mackerel, dried salt cod-fish, caviare, tinned salmon, and tinned sardines. Shell-fish may produce poisonous effects from putrefactive changes or from the development in them (oysters and mussels) of ptomaines. Brieger discovered a ptomaine in poisonous mussels to which he gave the name mytilotoxin. It is now fully proved that oysters and mussels may become contaminated with the organism of enteric fever if placed in specifically polluted water, and thus transmit the disease to human beings. Milk, as already stated, may be contaminated and convey the infection of scarlet fever and other diseases. It may also contain substances of bacterial origin, which are possibly the cause of infantile diarrhoea, and others, having a fatal effect upon adults. Cheese has frequently caused poisoning. Vaughan discovered a toxic substance in milk and cheese—tyrotoxin—but there are other toxic substances of bacterial origin sometimes present in cheese to which poisonous effects have probably been due. Mushroom poisoning results from the eating of poisonous fungi in mistake for the edible mushroom. The poisonous element in most cases is either muscarin contained in the fungus *Amanita muscaria*, or phallin in *Amanita phalloides*.

Medici, Giacomo, MARQUIS OF THE "VASCELLO" (1817–1882), Italian patriot and soldier, was born at Milan in January 1817. Exiled in 1836, he fought in Spain against the Carlists between 1836 and 1840, and in 1846 joined Garibaldi at Montevideo in the war with the dictator Rosas. Returning to Italy with Garibaldi in 1848, he raised a company of volunteers to fight against Austria, and commanded the volunteer vanguard in Lombardy, proceeding thence to Rome, where he gained distinction by his defence of the "Vascello," a position near the Porta San Pancrazio. During the siege he himself was wounded. In the war of 1859 he commanded a volunteer regiment, and was sent by Cavour into the Tirol. In 1860 he tried to dissuade Garibaldi from the Marsala expedition, but, after his chief's departure, sailed for Sicily with the second expedition, taking part in the whole campaign, during which he forced Messina to capitulate after an eight days' siege. Joining the regular army, he was appointed military commandant of Palermo, in which capacity he facilitated the abortive Garibaldian campaign of 1862. In 1866 he commanded the division which invaded Trent, but the effect of his victories was neutralized by the conclusion of peace. Returning to Palermo with instructions to suppress brigandage and crush the Mafia, he became involved in a quarrel with the procurator-general Tajani, and relinquished his post. Created senator in 1870, and marquis of the "Vascello" and first aide-de-camp to the king in 1876, he exercised the latter functions until his death on 9th March 1882. (H. W. S.)

MEDICINE.

IN the admirable survey of the history of Medicine in the ninth edition of this work the author carried the subject down to the middle of the 19th century. To appreciate and compare the various tendencies and achievements of our contemporaries in so large a sphere as that of medicine is very difficult, and in some sense impossible; yet at the beginning of the 20th century an attempt must be made to indicate the main lines on which medicine is advancing, and probably will advance. The progress of medicine, as of other arts depending directly on physical science, has been prodigious; both through the purgation and reform of its methods and through the discovery of new knowledge of wide practical bearings and of immediate utility. Medicine in the past has been variably dominated by three tendencies: in certain periods its professors pursued their study as naturalists—for example, Hippocrates, Sydenham, and Graves; or again as dialecticians, or reasoners in abstract terms—for example, the school of the "Methodists," the vitalist school of Montpellier, the animists, the iatro-physical school in which the body was regarded as an engine, the iatro-chemical in which it was regarded as an alembic, the Brunonian, and so forth. Finally, the modern school, though still naturalistic in its methods of clinical observation, has founded its methods more securely upon the tests of verification, after the example of Harvey and indeed of Galen himself, adding to experience the *experientia quasita* without which natural observation is incomplete. We shall not forget that the most scientific physician of our own day may fall into sophistry, and that the most abstract dialecticians of other times have deviated occasionally into positive methods, but it is mainly true that the prevailing bent of successive schools has varied after this fashion and that. Medicine, like other departments of human activity, has taken its colour from the character of the thought of the times. If sometimes medicine has seemed curiously independent of the philosophy of its age, it has never been really independent of it, nor could it possibly have such an independence. In our own day the positive bent of modern knowledge and methods in other spheres of science and thought, and especially in biology, has influenced medicine profoundly. Minuter accuracy of observation was inculcated by the labours and the teaching of the great anatomists of the 17th century; and, for modern times, experimental physiology was instituted by Harvey, anatomy having done little to interpret life in its dynamic aspects. For medicine in England Harvey did what Gilbert did for physics and Boyle for chemistry: he insisted upon direct interrogation of natural processes, and thereby annihilated the ascendancy of mere authority, which, while nations were in the making, was an essential principle in the welding together of heterogeneous and turbulent peoples. The degradation of medicine between Galen and Harvey, if in part it consisted in the blind following of the authority of the former physician, was primarily due to other causes; and its new development in the last two centuries is not due to the discovery of the experimental method alone: social and political causes also are concerned in the advance even of the exact sciences. Among such contributory causes is the more familiar intercourse of settled nations which we enjoy in our own day; the ideas of one nation rapidly permeate neighbouring nations, and by the means of printed books penetrate into remoter provinces and into distant lands. Hence in this article the description of the advance of medicine in western Europe and America

may be taken as a whole, without that separate treatment, nation by nation, which in the history of earlier times was necessary. Italy lost the leading place she had taken in the new development of science. The several influences of modern Germany, France, and America became of the first importance to English medicine; but these tides, instead of pursuing their courses as independent streams, have become confluent. The work of Schwann, Müller, Virchow, and Ludwig in Germany, of Laennec and Bernard in France, was accepted in England, as that of Matthew Baillie, Charles Bell, Bright, Graves, and others of the British school, quickly made itself felt abroad. Our survey of the medicine of the latter half of the 19th century then will not be divided into national histories; though in passing some special features in the work of each nation may have due notice.

GENERAL PROGRESS.

The character of modern medicine cannot be summed in a word, as, with more or less aptness, that of some previous periods may be. Modern medicine, like modern science, is as boldly speculative as it has been in any age, and yet it is as observant as in any naturalistic period; its success lies in the addition to these qualities of the method of verification; the fault of previous times being not the activity of the speculative faculty, without which no science can be fertile, but the lack of vigilant reference of all and sundry propositions, and parts of propositions, to the test of experiment. In no department is the experimental method more continually justified than in that of the natural history of disease; which at first sight would seem to have a certain independence of it and a somewhat exclusive value of its own. Hippocrates had no opportunity of verification by necropsy, and Sydenham neglected pathology; yet the clinical features of many but recently described diseases, such, for example, as that named after Graves, and myxœdema, both associated with perversions of the thyroid gland, lay as open to the eye of physicians in the past as to our own. Again, to the naturalist the symptoms of *tabes dorsalis* were visible enough, had he noted them. No aid to the trained eye was necessary for such observations, and for many other such; yet, if we take Sir Thomas Watson as a modern Sydenham, we find in his lectures no suspicion that there may be a palsy of muscular co-ordination apart from deprivation of strength. Indeed, it does not seem to have occurred to any one to test the muscular strength in the various kinds of paraplegia. Thus it was, partly because the habit of acceptance of authority, waning but far from extirpated, dictated to the clinical observer what he should see; partly because the eye of the clinical observer lacked that special training which the habit and influence of experimental verification alone can give, that physicians, even acute and practised physicians, failed to see many and many a symptom-group which went through its evolutions conspicuously enough, and needed for its appreciation no unknown aids or methods of research, nor any farther advances of pathology. We see that the practice of the experimental method endows with a new vision both the experimenter himself and, through his influence, those who are associated with him in medical science, even if the latter be not themselves engaged actually in experiment; a new discipline imposed upon old faculties, which is seen as well in other sciences as in those on which medicine more directly depends. And it is not only the perceptions of eye or ear which tell, but

*Experi-
mental
method
recognized.*

also the association of concepts behind these adits of the mind. It was the concepts derived from the experimental methods of Harvey, Lavoisier, Liebig, Claude Bernard, Helmholtz, Darwin, Pasteur, Lister, and others, which, directly or indirectly, trained the eyes of clinicians to observe more closely and accurately; and not of clinicians only, but also of pathologists, such as Matthew Baillie, Cruveilhier, Rokitansky, Bright, Virchow—to name but a few of those who, with (as must be admitted) new facilities for necropsies, began to pile upon us discoveries in morbid anatomy and histology. If at first in the 18th century, and in the earlier 19th, the discoveries in this branch of medical knowledge had a certain isolation, due perhaps to the prepossessions of the school of Sydenham, they soon became the property of the physician, and were brought into co-ordination with the clinical phenomena of disease. The great Morgagni, the founder of morbid anatomy, himself set the example of carrying on this study parallel with clinical observation; and always insisted that the clinical story of the case should be brought side by side with the revelations of the necropsy. In pathology, indeed, Virchow's influence in the transfiguration of this branch of science may almost be compared to that of Darwin and Pasteur in their respective domains (see PATHOLOGY). In the last quarter of the 19th century the conception grew clearer that morbid anatomy for the most part demonstrates disease in its static aspects only, and also for the most part in the static aspect of final demolition; and, as pathology and clinical medicine became more and more thoroughly integrated, it became manifest that the processes which initiate and are concerned in this dissolution were not revealed by the scalpel.

Again, the physician as naturalist, though stimulated by the pathologist to delineate disease in its fuller manifestations, yet was hampered in a measure by the didactic method of constructing "types" which should command the attention of the disciple and rivet themselves on his memory; thus too often those incipient and transitory phases which initiate the paths of dissolution were missed. Not only so, but the physician, thus fascinated by "types," and impressed by the silent monuments of the pathological museum, was led to localize disease too much, to isolate the acts of nature, and to forget not only the continuity of the phases which lead up to the exemplary forms, or link them together, but to forget also that even between the types themselves relations of affinity must exist—and these oftentimes none the less intimate for apparent diversities of form, for types of widely different form may be, and indeed often are, more closely allied than types which have more superficial resemblance—and to forget, moreover, how largely negative is the process of abstraction by which types are imagined. Upon this too static a view, both of clinical type and of *post-mortem* room pathology, came a despairing spirit, almost of fatalism, which in the contemplation of organic ruins lost the hope of cure of organic diseases. So prognosis became pessimistic, and the therapeutics of the abler men negative, until fresh hopes arose of stemming the tides of evil at their earliest flow.

Such was medicine, statically ordered in pathology, statically ordered in its clinical concepts, when, on the 24th of November 1859, the *Origin of Species* was published. It is no exaggeration to say that this epoch-making work brought to birth a world of conceptions as new as the work of Copernicus. For the natural philosopher the whole point of view of things was changed; in biology not only was the anthropocentric point of view banished, but the notion of perpetual flux was brought home to ordinary men, and entered for good into the common framework

of thought. The study of comparative pathology, yet in an inchoate stage, and of embryology, illuminated and enlarged biological conceptions, both normal and abnormal; and the *ens reale subsistens in corpore* disappeared for ever—at any rate from physiology and medicine. Before Darwin—if the name of Darwin may be used to signify the transfiguration of thought of which he was the chief artificer—natural objects were regarded, not in medicine and pathology only, as a set of hidebound events; and natural operations as moving in fixed grooves, after a fashion which it is now difficult for us to realize. With the melting of the ice the more daring spirits dashed into the new current with such ardour that for them all traditions, all institutions, were thrown into hotchpot; even elderly and sober physicians took enough of the infection to liberate their minds, and, in the field of the several diseases and in that of *post-mortem* pathology, the hollowness of classification by superficial resemblance, the transitoriness of forms, and the flow of processes, broke upon the view. Thus it came about not only that classifications of disease based on superficial likeness—such as jaundice, dropsy, inflammation—were broken up, and their parts redistributed, but also that even more set diseases began to lose their settlements, and were recognized as terms of series, as transitory or culminating phases of perturbations which might be traced to their origins, and in their earlier stages perhaps withstood.

The doctrine of heredity in disease thus took a larger aspect; the view of morbid series was no longer bounded even by the life of the individual; and the propagation of taints, and of morbid varieties of man, from generation to generation proved to be no mere repetition of fixed features but, even more frequently, to be modes of development or of dissolution betraying themselves often in widely dissimilar forms, in series often extending over many lives, the terms of which at first sight had seemed wholly disparate. Thus, for example, as generations succeed one another, nervous disorders appear in various guise; epilepsy, megrim, insanity, asthma, hysteria, neurasthenia, a motley array at first sight, seemed to reveal themselves as terms of a morbid series; not only so, but certain disorders of other systems also appeared to be members of the series, such as certain diseases of the skin, and even peculiar susceptibilities or immunities in respect of infections from without. On the other hand, not a few disorders proved to be alien to classes to which narrower views of causation had referred them; of such are tabes dorsalis, neuritis, infantile palsy, or tetanus, now removed from the category of primary nervous diseases and placed in one or other of the series of infections; or, conversely, certain forms of disease of the joints are now regarded with some certainty as members of more than one series of diseases chiefly manifest in the nervous system. In the effects of simpler poisons the recognition of unity in diversity, as in the affiliation of a peripheral neuritis to arsenic, illustrated more definitely this serial or etiological method of classifying diseases. On the other hand, inheritance was dismissed, or survived only as a "susceptibility," in the cases of tubercle, leprosy, and some other maladies now recognized as infectious; while in others, as in syphilis, it was seen to depend upon a translation of the infectious element from parent to offspring. These new conceptions of the multiplicity in unity of disease, and of the fluidity and continuity of morbid processes, might have led to vagueness and over-boldness in speculation and reconstruction, had not the experimental method been at hand with clues and tests for these series. Against such dangers the rise and wonderful extension of the science of bacteriology also furnished no inconsiderable safeguard.

In the disease of the scalp called favus, Schönlein had

discovered a minute mycelial fungus—a remarkable discovery; for it was the first conspicuous step in the attribution of diseases to the action of minute parasites. Schönlein thus did something to introduce new and positive conceptions and exacter methods into Germany; but unfortunately his own mind retained the abstract habit of his country, and his abilities were dissipated in the mere speculations of Schelling. Similarly Karl Hoffmann of Würzburg wasted his appreciations of the newer schools of developmental biology in fanciful notions of human diseases as reversions to normal stages of lower animals; scrofula being for him a reversion to the insect, rickets to the mollusc, epilepsy to the oscillaria, and so forth. Even that distinguished physiologist Johannes Müller remained a staunch vitalist. Fortunately Germany, which at the beginning of the century was delivered over to Brownism and vitalism and was deaf to Bichat, was rescued from this sort of barrenness by the brilliant experimental work of Claude Bernard and Pasteur in France—work which, as regards the attenuated virus, was a development of that of Edward Jenner, and indeed of Schwann—Koch worthily following Pasteur with his work on the bacillus of anthrax and with his discovery of that of tuberculosis; and by the cellular doctrine and abundant labours in pathology of Virchow (see *PATHOLOGY*). Brieger then discovered the toxins of certain infections; and Behring completed the sphere of the new study by his discovery of the antitoxins of diphtheria and tetanus. Although in practical medicine the subsequent results of Behring and his followers have hitherto been somewhat disappointing, for in diphtheria alone have these discoveries attained a signal therapeutical success (indeed toxic action and capacity for combining with antitoxin are unfortunately not identical), yet in transforming our conceptions of nosology, and in destroying the last strongholds of vitalism and teleology, they have been most fertile. If the striking conceptions of Ehrlich continue to prove as fertile in inspiring and directing research as at present they seem to be, another wide sphere of conceptions will be opened out not in bacteriology only, but also in pathological chemistry, and in molecular physics. Again, besides giving us the clue to the nature of many diseases and to the continuity of many morbid series, by bacteriology certain diseases, such as actinomycosis, have been recognized for the first time.

As the prevalence of the conceptions signified and inspired by the word "phlogiston" kept alive ontological notions of disease, so the dissipation of vitalistic conceptions in the field of physics prepared men's minds in pathology for the new views opened by the discoveries of Pasteur on the side of pathogeny, and of Cohnheim and of Metschnikoff on the dynamical side of histology. Of the older ontological notions of disease the strongest were those of the essence of fever and of the essence of inflammation. Broussais had done much to destroy the notion of fever as an entity, but by extravagances in other directions he had discredited the value of his main propositions. Yet, although, as Andral and other French physicians proved, it was extravagant to say that all fevers take their origin from some local inflammation, it was true and most useful to insist, as he vehemently insisted, that "fever" is no substance, but a generalization drawn from symptoms common to many and various diseases springing from many, various, and often local causes; from diseases agreeing perhaps only in the factor of elevation of the temperature of the body. To the establishment of this new conception the improvement and general use of the *clinical thermometer* gave invaluable advantages. This instrument,

Bacteriology.

now indispensable in our daily work at the bedside, had indeed long been known both to physiologists (Haller) and to clinicians. In the 19th century de Haen, and, in the United Kingdom, Cleghorn of Dublin and Currie, carried on the use of the thermometer in fevers; and on the Continent in later years von Bärensprung and Traube did the same service; but it is to the work of Wunderlich that we owe the establishment of this means of precision as a method of regular observation both in pathology and in clinical medicine. By his almost exhaustive comparison of febrile movements as symptomatic processes Wunderlich dealt the last blow to the expiring doctrine of the "entity" of "fever"; while on the clinical side Bretonneau and Louis, in 1862-72, by their careful clinical and pathological studies of forms of fever, relieved the new doctrine of the extravagances of Broussais, and prepared the way for the important distinction of enteric from typhus fever by A. P. Stewart, William Jenner, Budd, Murchison, Louis, Autenrieth, Magnus of Philadelphia, Huss, Gerhard, and others. By the learned and accomplished Trousseau British and German influences were brought into France. Meanwhile Cohnheim and Metschnikoff were also engaged in destroying the ontological conception not of fever only, but also of inflammation, of which, as a local event, an ontological conception was no less strongly implanted. By his researches on the migration of the white corpuscles of the blood Cohnheim, on the bases laid by Virchow, brought the processes of inflammation within the scope of the normal, seeing in them but a modification of normal processes under perturbations of relatively external incidence; even the formation of abscess was thus brought by him within the limits of perversion of processes not differing essentially from those of health; and "new formations," "plastic exudations," and other discontinuous origins of an "essential" pathology, fell into oblivion. And it is not alien from the present point of view to turn for a moment to the light thrown on the cardio-arterial pulse and the measurement of its motions by the more intimate researches into the phenomena of the circulation by many observers, among whom in the 19th century Hope, Marey, and Ludwig will always take a leading place. By them the demonstration of Harvey that the circulation of the blood is in large part a mechanical process, and nowhere independent of mechanical laws, was considerably enlarged and extended. In particular the fluctuations of the pulse in fevers and inflammations were better understood, and accurately registered; and we can scarcely realize now that before Harvey the time of the pulse seems not to have been counted by the watch. Discovery in these various directions then led physicians to regard fever and inflammation not as separable entities, but as fluctuating symptom-groups, due to swervings of function from the normal balance under contingent forces.

As to such reforms in our conceptions of disease the advances of bacteriology profoundly contributed, so under the stress of consequent discoveries, almost prodigious in their extent and revolutionary effect, the conceptions of the etiology of disease underwent no less a transformation than the conceptions of disease itself. It is proper to point out here how intimately a pathology thus regenerated modified current conceptions of disease, in the linking of disease to oscillations of health, and the regarding many diseases as modifications of the normal set up by the impingement of external causes; not a few of which indeed may be generated within the body itself—"autogenetic poisoning." The appreciation of such modifications, and of the working of such causes, has been facilitated greatly by the light thrown upon normal processes by advances in physiology; so dependent is each branch of knowledge upon the advances of contiguous and incident studies. To physiological

Fevers and Inflammations.

New conceptions of etiology.

chemistry we have been deeply indebted during the latter half of the 19th century. In Würzburg, in 1872, Hoppe Seyler gave a new beginning to our knowledge of the chemistry of secretion and of excretion; and later students have increased the range of physiological and pathological chemistry by investigations not only into the several stages of albuminoid material and the transitions which all food-stuffs undergo in digestion, but even into the structure of protoplasm itself. Digestion, regarded a generation ago as little more than a trituration and "coction" of ingesta, to fit them for absorption and transfer them to the tissues, now appears as an elaboration of peptones and kindred intermediate products which, so far from being always bland, and mere bricks and mortar for repair or fuel for combustion, pass through phases of change during which they become so unfit for assimilation as to be positively poisonous. The formation of prussic acid at a certain period of the vital processes of the lotus may be given as a simple example of such phases; and poisons akin to muscarin seem to arise frequently in development or regression, both in animals and plants. Thus the digestive function, in its largest sense, is now seen to consist not only in preparation and supply, but in no small measure also of protective and antidotal conversions of the matters submitted to it; coincidentally with agents of digestion proper are found in the circuit of normal digestion "anti-substances" which neutralize or convert peptones in their poisonous phases; an autochthonous ferment, such as rennet for instance, calling forth an anti-rennet, and so on. Now as our own bodies thus manipulate substances poisonous and antidotal, if in every hour of health we are averting self-intoxication, so likewise are we concerned with the various intruding organisms, whose processes of digestion are as dangerous as our own; if these destructive agents, incessantly no doubt gaining admission to our bodies, do not meet within us each its appropriate compensatory defensive agent, dissolution will begin. Thus, much of infection and immunity are proving to be but special cases of digestion, and teleological conceptions of protective processes are modified.

Under the name of chemotaxis (Pfeffer) are designated certain of the regulative adaptations by which such ends are attained. By chemical warnings the defensive processes seem to be awakened, or summoned; and when we think of the infinite variety of such possible phases, and of the multitude of corresponding defensive agents, we may form some dim notion of the complexity of the animal blood and tissues, and within them of the organic molecules. Even in normal circumstances their play and counterplay, attractive and repellent, must be manifold almost beyond conception; for the body may be regarded as a collective organization consisting of a huge colony of micro-organisms become capable of a common life by common and mutual arrangement and differentiation of function, and by toleration and utilization of each other's peculiar products; some organs, such as the liver, for example, being credited with a special power of neutralizing poisons, whether generated under normal conditions or under abnormal, which gain entrance from the intestinal tract. As a part of these discoveries has arisen another but kindred doctrine, that of "internal secretions" of juices prepared, not for excretion, or even to be poured into channels of partial excretion, but for the fulfilment of physiological ends in the processes of metabolism. It is probable not only that the secreted juices of specialized cells are thus set one against another in the body, but also that the blood itself in its cellular and fluid parts contains elements potent in the destruction of bacteria and of their secretions. Thus endowed, the

blood, unless overwhelmed by extraordinary invasions, does not fail in stability or self-purification, and bacteria are not detected in its current. So various are the conditions of self-regulation in various animals, both in respect of their peculiar and several modes of assimilating different foods, and of protecting themselves against particular dangers from without, that, as we might have expected, the bloods taken from different species, or even perhaps from different individuals, are found to be so different that the healthy serum of one species may be, and often is, poisonous to another; not in respect of adventitious substances, but because the phases of physiological change in different species do not harmonize, each by its peculiar needs having been modified in different ways until, in their several conditions of life, they vary so much about the mean as to become almost if not quite alien one to another.

In the preservation of immunity then, in its various degrees and kinds, not only is the chemistry of the blood to be studied, but also its histology. By his eminent labours in cellular pathology Virchow, and Metschnikoff later, gave the last blow to the mere humoral pathology which, after an almost unchallenged prevalence for some two thousand years, now finds a resting-place only in our nurseries. Now the cellular pathology of the blood, investigated by the aid of modern staining methods, is as important as that of the solid organs; no clinical investigator, indeed, apart from research, no practitioner at this day, can dispense with examination of the blood for purposes of diagnosis; its coagulability and the kinds and the variations of the cells it contains being evidence of many definitely morbid states of the body. Again, not only in certain diseases may strange cells be found in the blood (*e.g.*, in Myelogenic Leucæmia), but parasites also, certain protozoa (malaria), and even certain higher forms of animal life (Filaria, Tsetse disease, Texas fever) having been discovered therein, to the great advantage of medicine (see *PATHOLOGY: Parasitic Diseases*). It is interesting to note that even the large and well-known parasites of the intestinal canal come into line with the microbes, for it is now suspected that even the *Bothriocephalus latus*, for example, is not merely a mechanical irritant, or a mere competitor for nutriment, but is injurious to its host by an intoxication.

It is obvious that the results of such advances prescribe for the clinical physician methods which cannot be pursued without expert assistance; a physician engaged in busy practice cannot himself undertake even the verifications required in the conduct of individual cases. Skill in modern laboratory work is as far out of the reach of the untaught as performance on a musical instrument. In spite, therefore, of the encyclopædic tradition which has persisted from Aristotle through the Arab and mediæval schools down to Mr Herbert Spencer, it is forced upon us in our own day that in a pursuit so many-sided as medicine, whether in its scientific or in its practical aspect, we have to submit more and more to that division of labour which has been a condition of advance in all other walks of life. It is now fully recognized that diseases of infants and children, of the insane, of the generative organs of women, of the larynx, of the eye, have been brought successively into the light of modern knowledge by "specialists," and by them distributed to the profession; and that in no other way could this end have been attained. That the division of labour, which may seem to disintegrate our calling, really unites it, is well seen in the clinical laboratories which were initiated in the later 19th century, and which are destined to a great future. By the approach of skilled pathologists to the clinical wards, a link is

Specialism.

forged between practitioners and the men of science who pursue pathology disinterestedly. The first clinical laboratory seems to have been that of von Ziemssen at Munich, founded in 1885; and, although his example has not yet been followed as it ought to have been, enough has been done in this way, at Johns Hopkins University and elsewhere, to prove the vital importance of the system to the progress of modern medicine. At the same time provision must be made for the integration of knowledge as well as for the winning of it by several adits. A conspicuous example of the incalculable evil wrought by lack of integration is well seen in the radical divorce of surgery from inner medicine, which is one of the most mischievous legacies of the Middle Ages—one whose mischief is scarcely yet fully recognized, and yet which is so deeply rooted in our institutions, in the United Kingdom at any rate, as to be hard to obliterate. That the methods and the subject matter of surgery and of medicine are substantially the same, and that the advance of one is the advance of the other, the division being purely artificial and founded merely on accidents of personal bent and skill, must be insisted upon at this time of our history. The distinction was never a scientific one, even in the sense in which the word science can be used of the Middle Ages; it originated in social conceits and in the contempt for mechanical arts which came of the cultivation of "ideas" as opposed to converse with "matter," and which, in the dawn of modern methods, led to the derision of Boyle by Oxford humanists as one given up to "base and mechanical pursuits." Had physicians been brought into contact with facts as hard as were the surgeons of the 16th century (cf. Ambrose Paré, *SURGERY, Ency. Brit.* vol. xxii. p. 676), our art would not have lain so long in degradation. It is under this closer occupation with mechanical conditions that surgery to-day is said—not without excuse, but with no more than superficial truth—to have made more progress than medicine. Medicine and surgery are but two aspects of one art; yet even the history of modern medicine is thus divided, and it is from another article that the reader must learn how by the brilliant services of modern surgeons have been enforced the same methods and truths as we are learning in the field of medicine proper; how Pasteur shed light on both surgery and medicine, and how Lister, his disciple, penetrated into the secrets of wound fevers and septicæmia, whereby he illuminated surgery and medicine alike, and, in the one sphere as in the other, co-operated in the destruction of the idea of "essential fevers" and of inflammation as an "entity" (see LISTER). Together, then, with the necessary multiplication of specialism, one of the chief lessons of the latter moiety of the 19th century was the unity of medicine in all its branches—a unity strengthened rather than weakened by special researches, such as those into "medical" and "surgical" pathology, which are daily making more manifest the absurdity of the distinction. Surgeons, physicians, oculists, laryngologists, gynæcologists, neurologists and the rest, all are working in allotments of the same field, and combine to a common harvest.

While pathology then, which is especially the "science of medicine," was winning territory on one side from physiology, of which in a sense it is but an aspect, and on another by making ground of its own in the *post-mortem* room and museum of morbid anatomy, and was fusing these gains in the laboratory so as to claim for itself, as a special branch of science by virtue of peculiar concepts, its due place and provision—provision in the establishment of chairs and of special laboratories for its chemical and biological subdivisions—clinical medicine, by the formal provision of

disciplinary classes, was illustrating the truth of the experience that teaching and research must go hand in hand, the one reinforcing the other; that no teacher can attain great success unless he be engaged in research also; nay, that for the most part even the investigator needs the encouragement of disciples. Yet it was scarcely until the last quarter of the 19th century that the apprenticeship system, which was a mere initiation into the art and mystery of a craft, was recognized as antiquated; in its virtual exclusion of academic study, even mischievous; and that in place of it systematic clinical classes became part of the scheme of every efficient school of medicine. A condition of this advance was the need of a preliminary training of the mind of the pupil in pure science, even in physics and chemistry; that is to say, before his introduction into his professional studies. The founding of new teaching universities, in which England, and even France, had been at some disadvantage as compared with Scotland and Germany, strengthened the movement in favour of enlarging and liberalizing technical training, and of anticipating technical instruction by some broader scientific discipline; though, as in all times of transition, something was lost temporarily by a departure from the old discipline of the grammar school before a new scheme of training the mind in scientific habits and conceptions was established or fully apprehended. Yet on the whole, even from the beginning, the revolt was useful in that it shook the position of the "learned physician," who took a literary, fastidious, and meditative rather than an experimental interest in his profession, and, as in great part a descendant of the humanists, was never in full sympathy with natural science. At the risk no doubt of some defects of culture, the newer education cleared the way for a more positive temper, awoke a new sense of accuracy and of verification, and created a sceptical attitude towards all conventions, whether of argument or of practice. Among the drawbacks of this temper, which on the whole made for progress, was the rise of a school of excessive scepticism, which, forgetting the value of the accumulated stores of empiricism, despised those degrees of moral certainty that, in so complex a study and so tentative a practice as medicine, must be our portion for the present, and even for a long future; however great the triumphs of medicine may become. This scepticism took form in the school, most active between 1860 and 1880, known as the school of "Expectant Medicine." These teachers, genuinely touched with a sense of the scantiness of our knowledge, of our confidence in abstract terms, of the insecurity of our alleged "facts," case-histories, and observations, alienated by traditional dogmatism and disgusted by meddling polypharmacy—enlightened, moreover, by the issue of cases treated by means such as the homœopathic, which were practically "expectant"—urged that the only course open to the physician, duly conscious of his own ignorance and of the mystery of nature, is to put his patient under diet and nursing, and, relying on the tendency of all equilibria to recover themselves under perturbation, to await events (*Vis medicatrix nature*). Those physicians who had occupied themselves in the study of the exacter sciences, or more closely or more exclusively of the wreckage of the *post-mortem* room, were the strongest men of this school, whether in England or abroad.

But to sit down helpless before human suffering is an unendurable attitude. Moreover, the insight into origins, into initial morbid processes revealed by the pathologists, awoke more and more the hope of dealing with the elements of disease, with its first beginnings; and in the field of therapeutics, chemical and biological experiment was rapidly simplifying remedies and defining their virtues (PHARMACOLOGY), as in the case

Medical training.

Therapeutics.

of digitalis, mercury, and the iodides, so that these agents could be used at the bedside with more precision. Furthermore, the aversion from drugging had the advantage of directing men's minds from remedies taken from the region of the physical forces, of electricity (Duchenne), of gymnastics (Ling), of hydropathy (Priessnitz), of massage (Weir Mitchell), of climate (Sir James Clarke), of diet (Todd, King Chambers, &c.), and even of hypnotism (Baird); while with the improvement of the means of locomotion came the renewal of the old faith and the establishment of new methods in the use of mineral springs. These and such means, often in combination, took much of the place formerly given to the use of drugs.

Again, a like spirit dictated the use of the physical or "natural" methods on a larger scale in the field of prevention. From the new regard given by physiologists and pathologists to the study of origins, and in the new hopes of thus dealing with disease at its springs, not in individuals only but in cities and nations, issued the great school of Preventive Medicine, initiated in England (Parkes, Simon, Richardson, Acland, Buchanan), and forwarded in Germany by Pettenkofer. Hygiene became for pathology what "milieu" is for physiology. By the modification of physical conditions on a national scale a prodigious advance was made in the art of preventing disease. The ghastly roll of infantile mortality was quickly purged of its darkest features (Ballard and others); aided by bacteriology, sanitary measures attained some considerable degree of exactness; public medicine gained such an ascendancy that special training and diplomas were offered at universities; and in 1875 a consolidated Act was passed for the United Kingdom establishing medical officers of health, and responsible lay sanitary authorities, with no inconsiderable powers of enforcing the means of public health in rural, urban, port, and other jurisdictions, with summary methods of procedure. A department of public health was formed within the precincts of the Local Government Board; Government laboratories were established, and machinery was devised for the notification of infectious diseases. The enormous growth of towns during the second half of the 19th century was thus attended with comparative safety to these great aggregates of mankind; and the death-rates, so far from being increased, relatively decreased in substantial proportions. In 1878 an Act was passed giving like powers in the case of the infectious diseases of animals. The establishment in England of the Register of qualified practitioners and of the General Medical Council (in 1858) did something, however imperfectly, to give unity to the profession, unhappily bisected by "the two colleges"; and did much to organize, to strengthen, and to purify medical education and qualification. In 1876 women were admitted to the Register kept by the Council. In 1871 the Anatomical Act of 1832 was amended; and in 1876 the Vivisection Act was passed, a measure which investigators engaged in the medical sciences of physiology and pathology resented as likely to prevent in England the advance of knowledge of living function, both in its normal balance and in its aberrancies, and moreover to slacken that habit of incessant reference of propositions to verification which is as necessary to the clinical observer as to the experimentalist. However the opinion of later generations may stand in respect of the Vivisection Act, it will surely appear to them that the other Acts, largely based upon the results of experimental methods, strengthening and consolidating the medical profession, and fortifying the advance of medical education, led directly to a fundamental change in the circumstances of the people in respect of health. The intelligent classes have become far better educated in the laws of health, and less disposed

to quackery; the less intelligent are better cared for and protected by municipal and central authority. Thus the housing of the poor has been improved, though this difficult problem is yet far from solution; not the large towns only, but the larger villages also, are cleansed and drained; food has been submitted to inspection by skilled officers; water supplies have been undertaken on a vast scale; personal cleanliness has been encouraged, and with wonderful success efforts have been made to bring civilized Europe back from the effects of a long wave of Oriental asceticism, which in its neglect and contempt of the body led men to regard filth even as a virtue, to its pristine cleanliness under the Greeks and Romans. During the latter half of the 19th century the death-rate of many towns was reduced by something like 50 per cent. Some plagues, such as typhus fever, have been dispelled; others, such as enteric fever, have been almost banished from large areas; and there is much reason to hope that cholera and plague, if introduced, could not get a footing in western Europe, or in any case could be combated on scientific principles, and greatly reduced. Temperance in the use of alcohol has followed the demonstration not only of the gross exaggeration of its nutritive value, but also of its harmfulness, save in very small quantities. In the earlier part of the 19th century, and in remoter districts even in its later years, the use of alcohol was regarded not as a mere indulgence, but as essential to health: the example of teetotallers, as seen in private life and in the returns of the insurance offices, has undermined this mischievous belief. From the time of Plato medicine has been accused of ministering to the survival of unfit persons, and to their propagation of children. But bodily defect is largely a result of evil circumstances, in the prevention of which the physician is not unsuccessfully engaged. Thus the mean standard of health will be raised, perhaps enormously.

In the tropics, as well as in Europe, such methods and such researches threw new light upon the causes and paths of the terrible infections of these climates. In 1880, two years before Koch discovered the bacillus of tubercle, Laveran discovered the amœba of malaria, and truly conceived its relations to the disease; thus within two years were made two discoveries either of which was sufficient to make the honour of a century. Before the end of the 19th century this discovery of the blood parasite of malaria was crowned by the hypothesis of Manson, proved by Ross, that malaria is propagated by a certain genus of gnat, which acts as an intermediate host of the parasite. The 20th century, by means of this illumination of one of the darkest regions of disease, may diminish human suffering enormously, and may make habitable rich and beautiful regions of the earth's surface now, so far as man's work is concerned, condemned to sterility. Moreover, freedom of trade and of travel has been promoted by a reform of the antiquated, cumbrous, and too often futile methods of quarantine—a reform as yet very far from complete, but founded upon a better understanding of the nature and propagation of disease.

SPECIAL DEPARTMENTS.

Hitherto we have presented a survey of the progress of the science and practice of medicine on general lines; it remains to give some indication of the advance of these subjects of study and practice in particular departments. As regards infections, it is not to be supposed that our knowledge of these maladies has been advanced by pathology and bacteriology only. In the clinical field also it has received a great enlargement. Diphtheria, long no doubt a plague among mankind, was not carefully described until by Bretonneau in 1826; and

since his time our conception of this disease has been extended by the study of later, secondary, and incidental phases of it, such as neuritis, which had always formed part of the diphtheritic series, though their intimate connexion with it had not been suspected. Influenza, again, was well known to us in 1836-40, yet clinical observers had not traced out those sequels which, in the form of neuritis and mental disorder, have impressed upon our minds the persistent malignity of this infection, and the manifold forms of its activity. By the discovery of the bacillus of tubercle, the physician has been enabled to piece together a long and varied list of maladies under several names, such as scrofula and lupus, many of them long suspected to be tuberculous, but now known to be of the same series. It is on clinical grounds, for their respective specific agents are as yet unknown, that syphilis, beriberi, scarlet fever, measles, &c., are recognized as belonging to the same class, and evolving in phases which differ not in intimate nature but in the more superficial and inessential characters of time, rate, and polymorphism. On clinical grounds also the impression is gaining strength that acute rheumatism belongs to the group of the infections; and that certain sore throats, chorea, and other maladies apparently distinct, are terms of this series. Thus the field of disease arising not from essential defect in the body, but from external contingencies, is enlarging; while on the other hand the great variability of individuals in susceptibility explains the very variable results of such extrinsic causes. Coincidentally therewith, the hope of neutralizing infections by fortifying individual immunity has grown brighter, for it appears that immunity is not a very radical character, but one which, as in the case of vaccination, admits of modification and accurate adjustment in the individual, in no long time and by no very tedious methods. In a few years we may be able to do for other infections what we have done already for smallpox, for diphtheria, and perhaps for typhoid fever and cholera. The field of antitoxic treatment will also prove wider and wider as one disease after another falls into the category of contagious infection. Leprosy, for instance, is now traced to its own bacillus, and, the fatalist notion of heredity being thereby dispelled, the hope of prevention, based on a discovery of the nature of the infection, is awakened. Cholera seems to be falling into the power of the pathologist (Haffkine), and evidence is accumulating which may end in the explanation and perhaps in the prevention of the direst of human woes—cancer itself.

When, leaving the infections, we look for evidence of progress in our knowledge of more or less local diseases, we may begin with the nervous system. It is *Neurology*, in this department, from its abstruseness and complexity, that we should expect the advance of anatomy and physiology—normal and morbid—to be most delayed. If we consult the medical works even of the middle of the 19th century we shall find that, in the light of the present time, accurate knowledge in this sphere, whether clinical, pathological, or therapeutical, could scarcely be said to exist. Even in the hands of Lockhart Clarke, one of the earliest investigators of nervous pathology, the improvement of the compound microscope had not attained the achromatism, the penetration, and the magnification which have since enabled Schröder von der Kolk, Kölliker, Ramon i Cajal, Golgi, and others to reveal the minute anatomy of the nervous centres; while the discrimination of tissues and morbid products by stains, as in the silver and osmic acid methods, and in those known by the names of Weigert or Marchi, had scarcely begun. In England the Hospital for the Paralysed and Epileptic was founded in 1859, when Brown-Séquard, Hughlings-Jackson, Buzzard, Bastian, Gowers, and Ferrier found an adequate field for the

clinical and pathological parts of their work. In France, in the wards of the Hôtel Dieu, Duchenne of Boulogne, in association with Troussseau and in his private clinic, pursued his memorable clinical and therapeutical researches into the diseases of the nervous system; and Charcot in that great asylum for the wreckage of humanity—the Salpêtrière—discovered an unworked mine of chronic nervous disease. Romberg and Meynert also were pioneers in the study of nervous diseases, but it was not till later in the century that Germany took a high place in this department of medicine. The discoveries of the separate paths of sensory and motor impulses in the spinal cord, and consequently of the laws of reflex action, by Charles Bell and Marshall Hall respectively, in their illumination of the phenomena of nervous function, may be compared with the discovery in the region of the vascular system of the circulation of the blood; for therein a key to large classes of normal and aberrant functions and a fertile principle of interpretation were obtained. Nor was the theory of reflex action confined to the more “mechanical” functions. By G. H. Lewes and others the doctrine of “cerebral reflex” was established, whereby actions, at first achieved only by incessant attention, become organized as habits; as for instance in the playing on musical or other instruments, when acts even of a very elaborate kind may follow directly the impulses of sensations, conscious adaptation and the deliberate choice of means being thus economized. This law has important ethical and political bearings; but in the province of disease this advance of what may be called the interlocking of points and signals has had wide influence not only in altering our conceptions of disease itself, but also in enlarging our views of all perturbations of function. The paths whereby such impulses travel and become associated in the nervous system have been made out by the physiologist working on the healthy animal, as well as by the record of disease; and not by spontaneous disease alone, for the artificial institution of morbid processes in animals has led to many such discoveries, as in the method of Waller, who tracked the line of nervous strands by experimental sections, and showed that when particular strands are cut off from their nutritive centres the consequent degeneration follows the line of the separated strands. By similar methods nature, unassisted, betrays herself but too often; in many instances—probably originating primarily in the nervous tissues themselves—the course of disease is observed to follow certain paths with remarkable consistency, as for instance in diseases of particular tracts of the spinal cord. In such cases the paths of degeneration are so neatly defined that, when the tissues are prepared after death by modern methods, they are plainly to be seen running along certain columns, the subdivisions of which in the normal state are not to be distinguished one from another: some run in strips along the periphery of the spinal cord, at its anterior, middle, or posterior segments, as the case may be; or in other cases such strips occur within its substance, whether along columns of cells or of white matter. It is needless to point out how such paths of disease, in their association with characteristic symptoms, have illuminated the clinical features of disease as well as the processes of normal function.

Not, however, all diseases of the nervous system conduct themselves on these definite paths, for some of them pay no attention to the geography of function, but, as one may say, blunder indiscriminately among the several parts; others, again, pick out particular parts definitely enough, but not parts immediately continuous, or even contiguous. Diseases of the latter kind are especially interesting, as in them we see that parts of the nervous structure, separated in space, may nevertheless be associated in function; for

instance, wasting of a group of muscles associated in function may depend on a set of central degenerations concurring in parts which, in spite of dissociation in space, we thus infer to be connected. The undiscriminating diseases, on the other hand, we suspect not to be primarily of nervous origin, but to depend rather on the agency of other constituent tissues of this system, as of the blood-vessels or the connective elements. Thus, arguing inversely, we may learn something of the respective natures of these influences and of the way in which the nervous system is affected secondarily.

Even the distribution of toxic matters by the blood is not necessarily followed by general and indiscriminate injury to the nervous elements. In infantile palsy, for example, and in tabes dorsalis, there is good reason to believe that, definitely as the traces of the disease are found in certain physiologically distinct nervous strands, they are due nevertheless to toxic agents arriving by way of the blood. Here we enter upon one of the most interesting chapters of disorders and modes of disorder of this and of other systems. It has come out more and more clearly of late years that poisons do not betray even an approximately indifferent affinity for all tissues, which indeed a little reflection would tell us to be *à priori* improbable, but that each tends to fix itself to this cell

**Anchorage
of
molecules.**

group or to that, picking out parts for which they severally have an affinity. Neither chemical, physiological, nor pathological research has explained the secret of these more refined kinds of "anchorage" of molecules. In 1880 Drs Crum Brown and Fraser demonstrated the remarkable fact that by substitution of molecules in certain compounds a stimulant could be converted into a sedative action; thus by the addition of the methyl group CH_2 to the molecule of strychnine, thebaine, or brucine, the tetanizing action of these drugs is converted into a paralyzing action. The number of these instances, and the variety of them, are now known to be very large; and it is supposed that what is true of these simpler agents is true also of far more elaborate phases of vital metabolism. Now, what is remarkable in these and many other reactions is not only that effects apparently very opposite may result from minute differences of molecular construction, but also that, whatever the construction, agents not wholly indifferent to the body or part tend to anchor themselves to organic molecules in some way correlated with them. Highly complex as are all animal tissues, or nearly all, yet in this category of high complexity are degrees higher and higher again of which we can form little conception; so elaborate they are, so peculiar in their respective properties, and probably so fugitive. It is this wide range of dynamic peculiarities above the common range of known chemical molecules which excites our wonder; and a reflection of these peculiar properties is seen in their affinities for this or that toxic or constructive agent, whereby the peculiarity, for example, of a particular kind of nerve cell may be altered, antagonized, reinforced, or converted. On the other hand, the reagents by which such modifications are apt to be produced are not necessarily simple; many of them likewise are known to be of very high degrees of complexity, nearly as complex perhaps as the molecules to which they are akin. Of such probably are the toxins and antitoxins of certain infections, which, anchoring themselves not by any means indiscriminately, but to particular and concerted molecules, antagonize or convert them by such anchorage to favourable or unfavourable issues. Toxins, thus finding an anchorage in certain tissue molecules, may become so closely keyed into their corresponding atom groups, as for instance in tetanus, that they are no longer free to combine with the antitoxin; or, again, an antitoxin injected before a toxin may anticipate the

anchorage of the latter and, preventing its mischievous adhesion, may dismiss it for excretion. In the mutual behaviour of such cells, toxins and antitoxins, and again of microbes themselves, we may demonstrate even on the field of the microscope some of the modes of such actions, which seem to partake in great measure at any rate of a chemical character (agglutinins, coagulins, chemotaxis). It is convenient here to add that such reactions and modifications, if more conspicuous in the nervous system, are of course not confined to it, but are concerned in their degree in all the processes of metabolism, being most readily perceived by us in the blood.

Many other diseases formerly regarded as primarily diseases of the nervous system are not such; but, by means of agents either introduced into the body or modified there, establish themselves after the affinities of these in contiguous associated parts of the structure, as in vessels, membranes, or indeed in distant and peripheral parts; the perturbations of nervous function being secondary and consequential. Of such are tetanus and diphtheria, now known to be due to the establishment from without of a local microbial infection, from which focus a toxin is diffused to the nervous matter. The terrible nervous consequences of some forms of inflammation of the membranes of the brain, again, are due primarily to microbial invasion rather of the membranes than of their nervous contents; and many other diseases may be added to this list. The grave palsies in such diseases as influenza, diphtheria, beriberi, or ensuing on the absorption of lead, are not mainly central, but due to a symmetrical peripheral neuritis.

Among diseases not primarily nervous, but exhibited in certain phenomena of nervous disorder, are diseases of the blood-vessels. Much light has been thrown upon the variations of arterial and venous blood pressures by Ludwig and his many followers: *Individual forms of disease.* by them not only the diseases of the circulatory system itself are elucidated, but also those of other systems—the nervous, for instance—which depend intimately on the mechanical integrity of the circulation of the blood as well as on the chemical integrity of the blood itself. With changes of the pressures of the blood in arteries, veins, or capillaries, and in the heart itself and its respective chambers, static changes are apt to take place in these parts; such as degeneration of the coats of the arteries, due either to the silent tooth of time, to persistent high blood pressures, or to the action of poisons such as lead or syphilis. Syphilitic lesion of the arteries, and likewise of other fibrous tissues, often involves grave consequential damage to nervous structures fed or supported by such parts. Some of the most successful of the advances of medicine as a healing art have followed the detection of syphilitic disease of the vessels, or of the supporting tissues of nervous centres and of the peripheral nerves; so that the treatment of paralytic, convulsive, and other terrible manifestations of nervous disease thus secondarily induced is now undertaken in early stages with definite prospect of cure, by means of specific medication.

Not of less importance in this respect, and in other disorders, many of them of grave incidence, is the knowledge of the phenomena of embolism and of thrombosis, also gained during the latter half of the 19th century (Kirkes, Virchow). By embolism is meant the more or less sudden stoppage of a vessel by a plug of solid matter carried thither by the current of the blood, be it a little clot from the heart or, what is far more pernicious, an infective fragment from some centre of infection in the body, by which messengers new foci of infection may be scattered about the body. Thrombosis is an accident of not dissimilar character, whereby a vessel is blocked not

by a travelling particle, but by a clotting of the blood *in situ*, probably on the occasion of some injury to the epithelial lining of the vessel. Such injuries are apt to occur in syphilitic endarteritis, whereby an artery may be blocked permanently, as if with an embolus, and the area supplied by it, in so far as it was dependent upon this vessel, deprived of nutrition. These events, although far more injurious in the brain, the functions of which are far-reaching, and the collateral circulation of which is ill-provided, are seen very commonly in other organs also.

It is in the structure of the brain itself that modern research has attained the most remarkable success. In 1861 the centre of speech was detected, by a combination of clinical and pathological researches, by Broca. By these means also, in the hands of Hughlings-Jackson, and more conclusively by experimental research initiated by Fritsch and Hitzig, but pursued independently and far more systematically and thoroughly by Ferrier and his disciples, it has been proved that large areas of the cerebrum are occupied by many such centres, which preside over the formulation of sensations into purposive groups of motions (kinæsthesia of Bastian). The results of Ferrier's experimental researches on the constitution of the brain have transformed our conceptions of cerebral physiology, and thrown a flood of light on the phenomena of the diseases of the brain. Not only so, but this accurate mapping of the brain in areas of function now often enables the clinical physician to localize the position of disease; and, in a certain few cases of tumour or abscess, so precisely that he may be enabled to open the skull above the part affected and to extirpate it—an operation which is surely a triumph of science and technical skill (Lister, Macewen, Horsley). For the bearings of the conception of the neuron on physiology, and so on pathological processes, the reader is referred to the article under **PHYSIOLOGY, VI.**

In mental diseases little of first-rate importance has been done. The chief work has been the detection of chronic changes in the cortex of the brain, by staining and other histological methods, in degenerative affections of this organ (Meynert, Griesinger, Bevan Lewis); and in the separation from insanity as a primary disease of nerve substance of such diseases as general paralysis of the insane, which probably arise, as we have said, in contiguous structures—such as blood-vessels and connective elements—and invade the nervous matter secondarily. Furthermore, it has become more and more probable that general paralysis of the insane, like tabes dorsalis, belongs to the class of the infections, and of these to the syphilitic series. Other infections in like manner seem to injure the mental fabric; and more intrinsic toxic processes also are suspected on the detection of neurin and cholin in the fluids of the brain (Mott). Truer conceptions of normal psychology have transformed for us those of the morbid (Pinel, Griesinger, Maudsley, Mercier), and indicated more truly the relations of sanity to insanity. In the treatment of insanity little has been done but to complete the non-restraint system which in principle belongs to the earlier part of the century (Pinel, Tuke, Hill, Conolly) (see **INSANITY**, vols. xiii. and xxix.). An enormous accumulation of lunatics of all sorts and degrees seems to have paralysed public authorities, who, at vast expense in buildings, mass them more or less indiscriminately in barracks, and expect that their sundry and difficult disorders can be properly studied and treated by a medical superintendent at a comparatively low salary, with but young assistants under him, who may have a couple of thousand patients in his charge, together with the management of a huge institution. The life of these insane patients is as bright, and the treatment as humane, as a barrack life can be; but of science,

whether in pathology or medicine, there can be little. A step in advance has been made by the London County Council, which has established a central laboratory for its asylums, and placed an eminent pathologist at the head of it: from this laboratory valuable reports have already been issued. Provision for the reception and treatment of insanity in its earliest and more curable stages can scarcely be said to exist. Sufferers from mental disease are not to be regarded as troublesome persons to be hidden away in humane keeping, but as cases of manifold and obscure disease, to be studied and treated by physicians of the highest skill, whose attention to their proper work is undivided. The care and education of idiots, initiated by Guggenbuhl and others, has made good way in England, and if as yet insufficient, is good of its kind.

By the genius of Laennec diseases of the lungs and heart were laid on a foundation so broad that his successors have been occupied in detail and refinement rather than in reconstruction. In heart disease the chief work of the latter half of the 19th century was, in the first quarter, such clinical work as that of Stokes and Latham; and in the second quarter the fuller comprehension of the vascular system as a whole, with its cycles and variations of blood pressure, venous and arterial. By the greater thoroughness of our knowledge of the physics of the circulation (Marey, Ludwig) we have attained to a better conception of such events as arterial disease, apoplexy, "shock," and so forth. To the discovery of the parts played in disease by thrombosis and embolism we have referred above. With this broader and more accurate knowledge of the conditions of the health of the circulation a corresponding efficiency has been gained in the manipulation of certain remedies and new methods of treatment of heart diseases, as by baths and gymnastics, of which a more particular account will be found in the article on **THERAPEUTICS.**

As regards pulmonary disease, pneumonia has passed more and more definitely into the category of the infections: the invasion of the lungs and pleura by tuberculosis, now definitely recognized as an infection, has been more and more accurately followed; and the treatment of these diseases, in the spheres both of prevention and of cure, has undergone a radical change. Instead of the close protection from the outer air, the respirators, and the fancy diets of our fathers, the modern *poitrinaire* camps out in the open air in all weathers, is fed with solid food, and in his exercise and otherwise is regulated with minute particularity according to the indications of the clinical thermometer and other symptoms. The almost reckless reliance on climate, which, at Davos for instance, marked the transition from the older to the modern methods, has of late been sobered, and supplemented by more systematic attention to all that concerns the mode of life of the invalid. The result is that, both in physicians and in the public, a more hopeful attitude in respect of the cure of phthisis has led to a more earnest grappling with the infection in its earliest stages and in every phase, with a correspondingly large improvement in the methods of treatment. Indeed, in such early stages, and in patients who are enabled to command the means of an expensive method of cure, phthisis is no longer regarded as desperate; while for those who of their own means are unable to obtain these advantages, steps are being taken to provide by the erection of special sanatoriums on a more or less charitable basis. Perhaps no advance in medicine has done so much as the study of tuberculosis to educate the public in the methods and value of research in medical subjects, for the results, and even the methods, of such labours have been

brought home not only to patients and their friends, but also to the farmer, the dairyman, the butcher, the proprietors of public vehicles, and, indeed, to every home in the land.

It was in the management of pleurisies that the aid of surgical means first became eminent in inner disease. In the treatment of effusions into the pleura, and, though with less success, of pericardial effusions, direct mechanical interference was practised by one physician and another, till these means of attaining rapid and complete cure took their place as indispensable, and were extended from thoracic diseases to those of the abdominal and other inner parts formerly beyond the reach of direct therapeutics. Lister's discoveries brought these new methods to bear with a certainty and a celerity previously undreamed of; and many visceral maladies, such as stone of the kidney or gall-bladder, perityphlitis, ovarian dropsy, and even cancer of the stomach—which in the earlier part of the 19th century were either fatal or crippling—are now taken promptly and safely in hand, and dealt with successfully. We have said that this advance is often quoted, not very wisely, to signify that in modern progress "medicine" has fallen behind surgery—as if the art of the physician were not one and indivisible. A disease which cannot be got at by one method is reached by another; the division of the art being, as we have said, an unreal and mischievous survival of old and erroneous customs, perpetuated in England by a merely mechanical severance. That certain Fellows of the College of Physicians have personally taken operative procedures in hand is some good omen that in time this schism may be healed.

In the department of abdominal disease progress has been made, not only in this enormous extension of means of cure by operative methods, but also by similar means for the verification of diagnosis. The first recognition of a disease may be at a necropsy, but then usually by irresponsible pathologists; it is another matter when the physician himself comes under rebuke for failing to seize a way to cure, which he might have discovered, while the chance remained to him, by section of the abdomen during life. The abdomen is still "full of surprises"; and he who has most experience of this deceptive region will have least confidence in expressing positive opinions in particular cases of disease without operative investigation. Besides the attainments mentioned above, in respect of operative progress, many important revisions of older rule-of-thumb knowledge have come about, and not a few other substantial discoveries. Among the revisions may be adduced the new accuracy of our knowledge of dyspepsia, attained by analytic investigations into the contents of the stomach at various stages of digestion. By physical signs, and by examining the contents of the viscus recovered, for instance, after "test meals," the defects, whether of this secretion or of that, and again of its motor activity, the state of the pyloric orifice, the volume of the sac, and even its position in the cavity of the abdomen, may be surmised or ascertained, and dealt with as far as may be; so that the application of remedies after a mere traditional routine is no longer excusable. In our conceptions of the later stages of assimilation and of excretion, with the generation of poisons (auto-intoxication) in the intestinal tract, there is still much obscurity and much guess-work; but in some directions positive knowledge has been gained, partly by the physiologist, partly by the physician himself. Of such are the better understanding of the functions of the liver in normal catabolism, in the neutralization of poisons absorbed from the intestines or elsewhere, in the causation of jaundice, and in diabetes (Naunyn, Pavy). Nor must we forget the unfolding of a new chapter of disease, in the

nosology of the pancreas. In diabetes this organ seems to play a part which is not yet precisely determined; and one fell disease at least has been traced to a violent access of inflammation of this organ, caused perhaps by entry of foreign matters into its duct. The parts of the pancreas and spleen in digestion also are better understood, and this knowledge is turned to good effect in the interpretation of the motley group of dyspepsias and anæmias.

The peritoneum is no longer regarded with awe as inviolable; by modern methods, if not as manageable as other lymphatic sacs, it is at any rate accessible enough without substantial risk to life. Not only in its bacteriological relations are the conditions of peritonitis recognized in its various kinds, but also the state known as "shock" turns out to be largely mechanical, and avoidable by measures belonging in considerable part to this category. Thus, by the avoidance both of toxæmia and of shock, peritonitis and other dangers of the abdomen, such as strangulations or intussusceptions of the bowels, formerly desperate, can in many cases be dealt with hopefully and efficiently.

Our knowledge of diseases of the kidneys has made no great advance since the time of Bright. In the sphere of physiology and in the interpretation of associated arterial diseases much obscurity still remains; as, for instance, concerning the nature of the toxic substances which produce those bilateral changes in the kidneys which we call Bright's disease, and bring about the "uræmia" which is characteristic of it. Lardaceous disease, however, here and in other regions, now appears to be due to the specific toxins of pyogenetic micro-organisms. In stone of the kidney a great advance has been made in treatment by operative means, and the formation of these stones seems to recent observers to depend less upon constitutional bent (gout) than upon unhealthy local conditions of the passages, which in their turn again may be due to the action of micro-organisms.

To Addison's descriptions of pernicious anæmia, and of the disease of the suprarenal capsules which bears his name, little has been added: but Hunter's researches may explain the causes of the former; the latter proves to be tuberculous, and on its fall of blood pressure physiologists have thrown some light.

The secret of the terrible puerperal septicæmia was read by Semmelweiss (*q.v.*), wherein he proved himself to be the greatest of Lister's forerunners (see LISTER).

The diseases peculiar to women have received attention from early times, but little progress had been made in their interpretation till the 19th century. In the middle part of the century, by a natural exaggeration of the importance of newly-discovered local changes in the pelvic organs, much harm was done to women by too narrow an attention to the site, characters, and treatment of these; that which in the physician was meddlesomeness becoming in the temperament of woman a morbid obsession. To Matthews Duncan we chiefly owe a saner and broader comprehension of the relative importance of the local and the general conditions which enter into the causation of uterine and ovarian disorders. For the success of operative means in diseases of the pelvis, in ovarian dropsy, in cancer of the uterus, and in other grave diseases of the region, a success which may be called stupendous, the reader is referred to the article on SURGERY.

In the subject of diseases of the skin much has been done, in the minuter observation of their forms, in the description of forms previously unrecognized, and in respect of causation and treatment. In the former line of research the comparison of observations in various climates and peoples has had some weight; while in the better knowledge of their causes their treatment has found permanent

advantage. Not only is the influence of bacteria in the causation of many of them newly revealed, but it is now recognized also that, even in skin diseases not initiated by microbial action, microbes play a considerable and often a determining part in their perpetuation; and that the rules of modern aseptic surgery are applicable with no little success to skin therapeutics. We have learned that "constitutional" causes play a smaller part in them than was supposed, that a large number of diseases of the skin are local diseases, either initiated by local infection or perpetuated thereby, and that, generally speaking, they are to be cured by local means.

The diseases of children have not lacked the renewed attention, the successful investigation, and the valuable new lights which have been given to other departments of medicine. That infantile palsy is an infection, and that its unhappy sequels are now treated with more hope of restoration, has been indicated already. Infantile diarrhoea has also been recognized as an infection (Ballard), and the means of its avoidance and cure ascertained; the conditions of digestion in children are now far better understood, and many of their maladies, formerly regarded as organic or incomprehensible, are referred to errors in diet, and cured or prevented by dietetic rules. Rickets, scurvy, and "tabes" may be instanced as diet diseases in children. Acute inflammation of the ear, with its alarming extensions to the cerebral cavity, is now often dealt with successfully by surgical means, and infected sinuses or encephalic abscesses are reached and cleansed. The origins, kinds, and processes of meningitis are more clearly distinguished, and referred each to its proper cause—for the most part bacterial.

As by the discovery of stethoscopy by Laennec a new field of medical science and art was opened up, so, more recently, inventions of other new methods of investigation in medicine have opened to us other fields of little less interest and importance. Of such is the ophthalmoscope, invented by Helmholtz in 1851. By the revelations of this instrument not only have the diseases of the eye been illuminated, but much light has been thrown also upon the part of the eye in more general maladies; as, for instance, in syphilis, in diabetes, in kidney diseases, and in diseases of the brain (Donders, von Graefe, and others). A remarkable help to the cure of headaches and other nervous disorders has come out of the better appreciation and correction of errors of refraction in the eye. Radiography has done great things for surgery; for medicine its services are already appreciable, and may prove more and more valuable hereafter. In 1879 the use of the spectroscope in medicine was pointed out by Dr M^r Munn. By du Bois-Reymond, Remak, Matteucci, Duchenne, the value of electricity in medicine, greater in diagnosis perhaps than in therapeutics, was demonstrated. By the sphygmograph (Marey, 1863) attention was drawn to the physical features of the circulation, to the signs of degeneration of the arterial tree, and less definitely to the fluctuations of blood pressure; but the kymographs of Ludwig and his pupils brought out these features far more accurately and completely, as we have said under the consideration of diseases of the heart. By these, and other instruments of precision, such as the thermometer, of which we have already spoken, the eminently scientific discipline of the measurement of functional movements, so difficult in the complex science of biology, has been cultivated. By the laryngoscope, invented about 1850 by Manuel Garcia, the celebrated singing-master, and perfected by Czermak and others, the diseases of the larynx also have been brought into the general light which has been shed on all fields of disease; and many of them, previously known more or less empirically, were submitted to precise definition and cure.

Of such we may cite tuberculosis of the larynx, formerly as incurable as distressing; and "adenoids"—a disease revealed by intrascopic methods—which used to thwart and stifle the growth both of mind and body in children, but are now removed early and promptly, to the infinite advantage of the rising generation. To the value of stains in clinical diagnosis, especially in investigation of perversions of the blood in leucæmia, and so forth, we have already made some reference. The discovery of the Röntgen rays has also extended the physician's power of vision, as in aortic aneurysm, and other thoracic diseases.

By photography and diagrammatic records the clinical work of hospital wards has been brought into some better definition, and teaching made more accurate and more impressive. The separation of the alkaloids belongs rather to the earlier part of the 19th century, but the administration of these more accurate medications by means of hypodermic injection (see THERAPEUTICS) belongs to the latter. The ancient practice of transfusion has been placed on a more intelligible footing, and made more manageable as a means of cure or relief. Finally, calculation by statistics (Farr and others) has been brought into line with other scientific methods: although the method is a difficult one, and one full of pitfalls for the unwary, yet when perfected and the sources of its materials purified, its services will appear more and more indispensable.

Among the achievements of the medicine of the 19th century, the growth of the medical press must not be forgotten. In England, by the boldness of the *Lancet* (founded in 1823) the tyranny of prescription, inveterate custom, and privilege abused was defied and broken down; freedom of learning was regained, and promotion thrown open to the competent, independently of family and professional status. For the record and diffusion of rapidly growing knowledge, learned societies, universities, and laboratories, greatly increased in number and activity, issue their transactions in various fields; and by means of year-books and central news-sheets the accumulation of knowledge is organized and made accessible.

It is interesting to find that, with all this activity in the present, reformed methods of research and verification are not confined to the work of the passing day; in the brilliant achievements of modern research and reconstruction the maxim that "Truth is the daughter of Time" has not been forgotten. In the field of the History of Medicine the work of scholars such as Greenhill and Creighton in England, Daremberg in France, and Haeser and Hirsch in Germany, will prove to our children that tradition was as safe in our hands as progress itself.

(T. C. A.)

Medina, a city of Orleans county, New York, U.S.A., in the north-western part of the state, on the Erie canal and the New York Central and Hudson River railroad. Its site is level and its plan regular. It has varied manufactures, and there are quarries of Medina sandstone in the vicinity. Population (1890), 4492; (1900), 4716, of whom 857 were foreign-born and 30 were negroes.

Medina, Jose Toribio (1852—), Chilian bibliographer, was born at Santiago in 1852, and was educated for the bar. His first publication, when a very young man, was a metrical translation of Longfellow's *Evangeline*. At the early age of twenty-two he was appointed secretary to the legation at Lima. After his return he published a history of Chilian literature (1878), and a work upon the aboriginal tribes (1884). In this latter year he was appointed secretary of legation in Spain, and availed himself of the opportunity of examining the treasures of the old Spanish libraries. These researches, repeated on occasion of subsequent visits to Spain, and

also to France and England, enriched him with a mass of historical and bibliographical material, which he turned to account in a series of publications evincing almost incredible activity and industry. Among them may be specially mentioned the *Biblioteca Hispano-Americana*, a verbatim catalogue of all books and pamphlets relating to Spanish America printed in Spain; the *Biblioteca Hispano-Chilena*, a similar work, commenced in 1897; the standard and magnificent history of printing in the La Plata countries (1892); comprehensive works on the Inquisition in Chile, Peru, and the Philippines; and the standard treatise on South American medals (1899). In addition, Señor Medina produced the fullest bibliographies yet attainable of books printed at Lima, Mexico, and Manila, and a number of memoirs and other minor writings. No other man had rendered anything like the same amount of service to the literary history and bibliography of the Spanish colonies. Most of his later works were printed at his own house.

Medina Sidonia, a town and railway station of Spain, in the province of Cadiz. The population in 1897 was 10,929. It is the centre of the trade of the surrounding district in agricultural products, particularly wheat, olives, and oats, and contains two parish churches, several convents, a large town hall, a fine Gothic church, and the ancestral palace of the dukes of Medina Sidonia, the title conferred by John II. in 1445 on Juan Alonzo de Guzman, count of Niebla, a descendant of the famous Alonzo Perez de Guzman el Bueno. From this house sprang a long line of statesmen, generals, colonial viceroys, including the Duke Alonzo Perez de Guzman, captain-general of the ocean and commander of the Invincible Armada that came to grief on the shores of Great Britain. The titles and grandeeships passed, in accordance with Castilian law, by marriage of a daughter and heiress in 1777, to the marquess of Villafranca, and have since remained in that noble house.

Medinet-el-Fayum, a city of Middle Egypt, capital of the province of Fayum, connected by a branch line 5 miles long with El Wasta, which is a station on the Nile Valley railway, 56 miles from Cairo. It is a great agricultural centre, with a population which increased from 26,000 in 1882 to 40,000 in 1900, and has several large bazaars, mosques, baths, and a much-frequented weekly market. The town stands on one of the two main branches of the Bahr Yusuf, which conduct the flood waters of the Nile to the Fayum, and have here the aspect of natural rivers. The neighbouring mounds mark the site of Arsinoë (Crocodylopolis), that is, the Egyptian city of Shat, where was worshipped the sacred crocodile kept in Lake Mœris.

Mediterranean Sea.—The Mediterranean is all that remains of a great ocean which at an early geological epoch, before the formation of the Atlantic, encircled half the globe along a line of latitude. This ocean, already diminished in area, retreated after Oligocene times from the Iranian plateau, Turkestan, Asia Minor, and the region of the north-west Alps. Next the plains of eastern Europe were lost, then the Aralo-Caspian region, southern Russia, and finally the valley of the Danube. The "Mediterranean region," as a geographical unit, includes all this area; the Black Sea and the Sea of Marmora are within its submerged portion, and the climate of the whole is controlled by the oceanic influences of the Mediterranean Sea. Prof. Suess, to whom the above description is due, finds that the Mediterranean forms no exception to the rule in affording no evidence of elevation or depression within historic times; but it is

noteworthy that its present basin is remarkable in Europe for its volcanic and seismic activity. Submarine earthquakes are in some parts sufficiently frequent and violent as to seriously interfere with the working of telegraph cables. Suess divides the Mediterranean basin into four physical regions, which afford probably the best means of description:—(1) The western Mediterranean, from Gibraltar to Malta and Sicily, enclosed by the Apennines, the mountains of northern Africa, and of southern and south-eastern Spain (*Cordillère bétique*). (2) The Adriatic, occupying the space between the Apennines and the Dinaric group (Suess compares the Adriatic to the valley of the Brahmaputra). (3) A part surrounded by the fragments of the Dinaro-Taurus arch, especially by Crete and Cyprus. This includes the Ægean and the Black Sea, and its margin skirts the south coast of Asia Minor. These three parts belong strictly to Eurasia. (4) Part of the coastal region of Indo-Africa, terraced downwards in successive horizontal planes from the Shot, reaching the sea in the Little Syrte, and continuing to the southern depressions of Syria. Malta and Gozo are the only islands of the Mediterranean which can be associated with this section, and, *per contra*, the mountain chain of north-west Africa belongs to Eurasia. Murray (1888) estimates the total area of the Mediterranean at 813,000 square miles. Karstens (1894) breaks it up into parts as follows:—

Western Mediterranean	841,593 sq. km.
Sicilian-Ionian basin	767,658 "
Greece and Levant basin	769,652 "
Adriatic Sea	130,656 "
Total	2,509,559 "

Murray estimates the total surface of the Mediterranean drainage area, with which must be included the Black Sea, at 2,934,500 square miles, of which 1,420,800 are Eurasian and 1,513,700 are African. The principal rivers entering the Mediterranean directly are the Nile from Africa, and the Po, Rhone, and Ebro from Europe.

The physical divisions of the Mediterranean given above hold good in describing the form of the sea-bed. The western Mediterranean is cut off by a bank crossing the narrow strait between Sicily and Cape Bon, usually known as the Adventure Bank, on which the depth is nowhere 200 fathoms. The mean depth of the western basin is estimated at 881 fathoms, and the deepest sounding recorded is 2040 fathoms. In the eastern Mediterranean the mean depth is nearly the same as in the western basin. The Sicilian-Ionian basin has a mean depth of 885 fathoms, and the Levant basin, 793 fathoms. Deep water is found close up to the coast of Sicily, Greece, Crete, and the edge of the African plateau. The steepest slope observed occurs off the island of Sapienza, near Navarino, where 1720 fathoms has been obtained only 10 miles from land. In 1897 the ship *Washington* obtained depths of 2220 fathoms in the middle of the eastern Mediterranean, and the Austrian expeditions in the *Pola* discovered in the "Pola Deep" (35° 44' N., 21° 45' E.), south-west of Cape Matapan, a maximum depth of 2406 fathoms. Between these two deep areas a ridge runs in a north-westerly direction 550 fathoms from the surface—possibly a projection from the African plateau. Another bank 1100 fathoms from the surface runs south from the east end of Crete, separating the Pola Deep from the depths of the Levant basin, in which a depth of 1960 fathoms was recorded near Makri on the coast of Asia Minor. The later expedition of the *Pola* discovered the "Rhodes Deep" (36° 5' N., 28° 36' E.), with a maximum depth of 2110 fathoms: this deep is closed to the south-east by a ridge running south-east, over which the depth is 1050 fathoms. Off the coast of Syria the *Pola* obtained four soundings of more than 1100 fathoms, and between Cyprus

and the coast of Asia Minor only two over 550 fathoms. Murray gives the following figures for the areas and volumes of the Mediterranean at different depths:—

Depth. Fathoms.	Area. Sq. Miles.	Volume. Cub. Miles.
0-100	201,300	80,950
100-500	251,650	220,850
500-1000	81,300	189,200
1000-2000	263,250	217,050
Over 2000	15,500	1,750
	813,000	709,800

which gives a mean depth over all of 768 fathoms. The following table is due to Karstens:—

	Volume. Cub. Km.	Mean Depth. Fathoms.
Western Mediterranean	1,356,512	881
Sicilian-Ionian basin	1,242,549	885
Levant	1,116,599	793
Adriatic Sea	31,844	133

Meteorology.—As already stated, the "Mediterranean region" forms a distinct climatic unit, due to the Mediterranean Sea. The prevailing winds in this region, which the sea traverses longitudinally, are westerly, but the sea itself causes the formation of bands of low barometric pressure during the winter season, within which cyclonic disturbances frequently develop, while in summer the region comes under the influence of the polar margin of the tropical high-pressure belt. Hence the Mediterranean region is characteristically one of winter rains, the distinctive feature becoming less sharply defined from south to north, and the amount of total annual fall increasing in the same direction. The climate becomes, on the whole, more continental in type from west to east, but there are great local irregularities—the elevated plateaux of Algeria and Spain cause a rise of pressure in winter and delay the rainy seasons: the rains set in earlier in the west than in the east, and the total fall is greater. Temperature varies greatly, the annual mean varying from 56° F. to 77° F. In the west the Atlantic influence limits the mean annual range to about 10°–12° F., but in the east this increases to 36° and even 40°. Autumn is warmer than spring, especially in the coastal regions, and this is exaggerated in the eastern region by local land winds, which replace the cool sea-breezes of summer: overcoats are ordinarily worn in Spain and Italy till July, and are then put aside till October. Local winds form an important feature in nearly all the coast climates of the Mediterranean, especially in winter, where they are primarily caused by the rapid change of temperature from the sea to the snow-clad hinterlands. Cold dry winds, often of great violence, occur in the Rhone valley (the Mistral), in Istria, and Dalmatia (the Bora), and in the western Caucasus. In summer a north-west "trade" wind, the Maestro, occurs in the Adriatic. The Sirocco is a cyclonic wind characteristic of the winter rainy season; in the Adriatic it is usually accompanied by cloud and moisture, often by rain. In Sicily and southern Italy the Sirocco occurs at all seasons; it is a dry, dusty wind from south-east or south-west. The dust is chiefly of local origin, but partly comes from the Sahara. Similar winds are met with in Spain (the Leveche), but they reach their greatest development in the Simooms of Algeria and Syria, and the Khamsin of Egypt.

Temperature.—The mean surface temperature of the waters of the Mediterranean falls from south-east, where it is over 70°, to north-west, the average at the coast of the Gulf of Lyons being 60°. The isothermal of 65° runs from Gibraltar to the north of Sardinia, and thence by the Strait of Messina to the Gulf of Corinth. A similar distribution is found 100 fathoms from the surface, temperature falling from 60° in the Levant to 55° east of Gibraltar. At 200 fathoms temperature falls in the same way

from 58° to 55°, but below 250 fathoms temperatures are practically uniform to the bottom, 55.5° in the western basin and 56.5° in the eastern. The bottom temperature observed in the Pola Deep was 56.3°.

Salinity.—In the extreme west the salinity of the surface water is about 36.3 *per mille*, and it increases eastwards to 37.6 east of Sardinia and 39.0 and upwards in the Levant. Observations of salinity in the depths of the western Mediterranean are very deficient, but the average is probably between 38.0 and 38.5. In the eastern basin the *Pola* expedition observed salinities of 38.7 to 39.0 to the east of a line joining Cape Matapan with Alexandria, and 38.2 to 38.7 to the west of it. The saltier waters apparently tend to make their way westwards close to the African coast, and at the bottom the highest salinities have been observed south of Crete. Evnitzki states that the saltiest water of the whole basin occurs in the Aegean Sea.

Circulation.—There is little definite circulation of water within the Mediterranean itself. In the straits joining it with the Atlantic and the Black Sea the fresher surface waters of these seas flow inwards to assist in making good the loss by evaporation at the surface of the Mediterranean, and in both cases dense water makes its way outwards along the bottom of the channels, the outflowing currents being less in volume and delivery than the inflowing. Elsewhere local surface currents are developed, either drifts due to the direct action of the winds, or streams produced by wind action heaping water up against the land, but these nowhere rise to the dignity of a distinct current system, although they are often sufficient to obliterate the feeble tidal action characteristic of the Mediterranean. Dr Natterer, the chemist of the *Pola* expeditions, has expressed the opinion that the poverty of the pelagic fauna is solely due to the want of circulation in the depths.

Deposits.—A great part of the bottom of the Mediterranean is covered with blue muds, frequently with a yellow upper layer containing a considerable proportion of carbonate of lime, chiefly shells of pelagic Foraminifera. In many parts a calcareous or silicious crust, from half an inch to three inches in thickness, is met with; and Natterer suggested that the formation of this crust may be due to the production of carbonate of ammonium where deposits containing organic matter are undergoing oxidation, and the consequent precipitation of carbonate of lime and other substances from the waters nearer the surface. This view, however, has not met as yet with very general acceptance. (H. N. D.)

Meerane, a town in Germany, 9 miles by rail north of the town and in the circle of Zwickau, kingdom of Saxony; station on the Gössnitz-Glauchau railway. It has *real*, commercial, and technical schools, and is one of the most important places in Germany for the manufacture of woollens and mixed cloths, having, in addition to work done in houses, 9 weaving mills, a worsted-spinning mill, and other factories. Population (1890), 22,446; (1901), 23,797.

Meerut, a city, district, and division of British India, in the North-West Provinces. The city is half-way between the Ganges and the Jumna, and has two stations on the North-Western railway, 37 miles north-east from Delhi. Population (1881), 99,965; (1891), 119,390; (1901), 118,642; municipal income (1897–98), Rs.2,06,111, mainly derived from octroi; incidence of taxation, R.1:2:1 per head; registered death-rate (1897), 35.7 per thousand. It is the headquarters of a military division, with accommodation for horse and field artillery, British and native cavalry and infantry. The aided college, opened in 1895, had 63 students in 1896–97. There are 3 high schools,

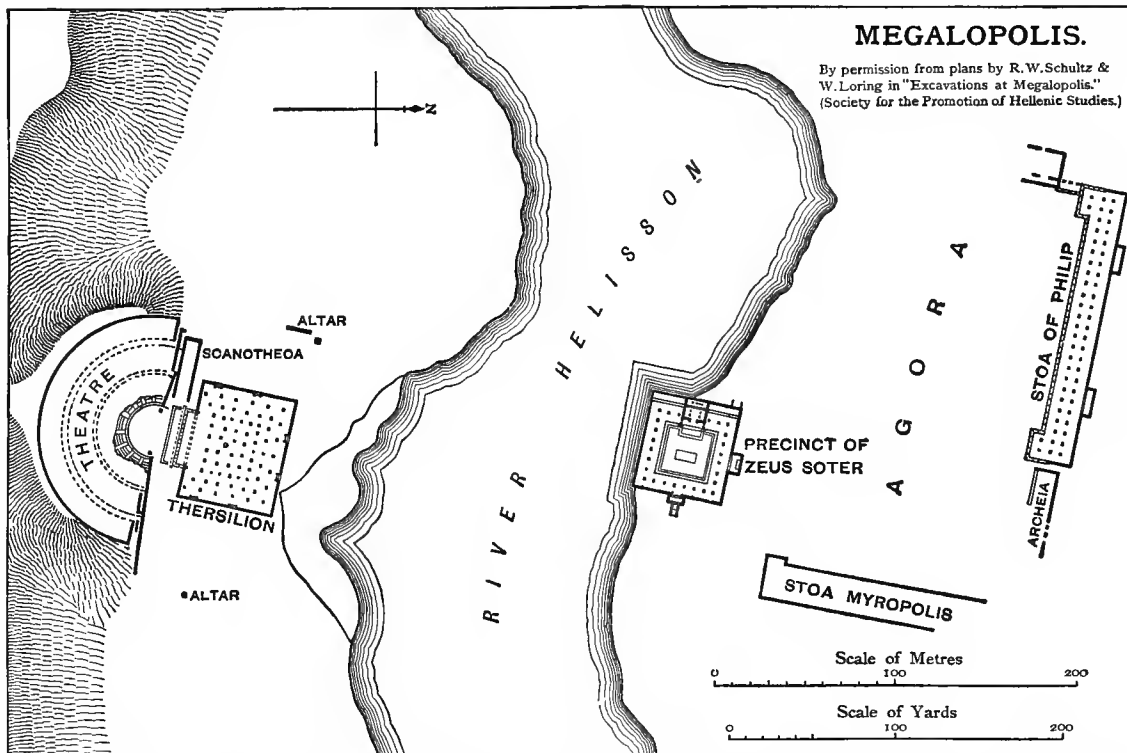

and 25 printing-presses, most of which issue a vernacular newspaper, besides 3 literary associations. The municipal water-works provides 7 gallons a day of filtered water per head, at a total cost of about 6 annas per thousand gallons.

The district of MEERUT forms part of the upper Doab, or tract between the Ganges and the Jumna, extending from river to river. Area, 2370 square miles; population (1881), 1,313,137; (1891), 1,391,458; (1901), 1,539,917, showing an increase of 6 per cent. between 1881 and 1891, and of 10.7 per cent. between 1891 and 1901; average density, 649 persons per square mile. The land revenue and rates were Rs.26,31,762, the incidence of assessment being R.1:7:5 per acre; the cultivated area in 1896-97 was 1,068,375 acres, of which 265,912 were irrigated, including 172,254 from Government canals; number of police, 3009; number of vernacular schools, 294, with 8119 pupils; registered death-rate (1897), 27.8 per thousand. The principal crops are wheat, pulse, millet, sugar-cane, cotton, and indigo. There are 63 indigo factories, with an out-turn valued at Rs.4,58,000. The district is watered by the eastern Jumna canal, and also by two branches of the

Ganges canal. It is traversed by the North-Western railway, and also contains Ghaziabad, the terminus of the East Indian system, whence a branch runs to Delhi and another (under construction) to Moradabad.

The division of MEERUT comprises the northern portion of the Doab. It consists of the six districts of Dehra Dun, Saharanpur, Muzaffarnagar, Meerut, Bulandshahr, and Aligarh. Area, 11,326 square miles; population (1881), 5,141,204; (1891), 5,326,833; (1901), 5,983,302, showing an increase of 12.3 per cent. between 1891 and 1901; average density, 528 persons per square mile.

Megalopolis.—The site of Megalopolis was excavated by members of the British School at Athens in the years 1890-92. No early remains were to be expected, since the city was founded by Epaminondas in 370 B.C. to unite the scattered Arcadians as a counterpoise to the power of Sparta; but on the other hand, the description of Pausanias indicated that the town was laid out on a plan specially adapted to the federal capital, and this description is so clear and explicit that it enables Curtius, in his

Walker & Cockerell sc.

Peloponnesos, to give a conjectural plan that was found to tally in most respects with the reality. The town was divided into two approximately equal parts by the river Helisson, which flows through it from east to west. The line of the walls may still be traced, partly by extant remains, partly by the contours it must have followed, and confirms the estimate of Polybius that they had a circuit of 50 stades or about $5\frac{1}{2}$ miles. It is difficult to see how the river bed, now a broad and shingly waste, was dealt with in ancient times; it must have been embanked in some way, but there are no remains to show whether the fortification wall was carried across the river at either end, or along the parallel embankments so as to make two separate enclosures. There must have been, in all probability, a bridge to connect the two halves of the city, but the foundations seen by Leake and others, and commonly supposed to belong to such a bridge, proved to be only the substructures of the precinct of Zeus Soter. The buildings to the north of the river were of a municipal character, and were grouped round the square agora. One, of which the complete plan has been recovered, is the

portico of Philip, a splendid building, which bounded the agora on the north; it was 300 feet long, with three rows of columns running its whole length, three in the outer line to each one in the two inner lines; it had a slightly projecting wing at either end. At the south-west of the agora was found the precinct of Zeus Soter: it consists of a square court surrounded by a double colonnade, and faced on the west side by a small temple; on the east side was an entrance or propylaeum approached by a ramp. In the midst of the court was a great substructure which has been variously interpreted as an altar or as the base of the great group of Zeus and Megalopolis, which is recorded to have stood here. North of this was the Stoa Myropolis, forming the east boundary of the agora, and, between this and the Stoa of Philip, the Archeia or municipal offices. These buildings were of various dates, but seem all to fit into a harmonious plan. The buildings on the south and west of the agora have been almost entirely destroyed by the Helisson and a tributary brook. On the south bank of the river were the chief federal buildings, the theatre (noted by Pausanias as the largest in Greece),

and the Thersilion or parliament hall of the ten thousand Arcadians. These two buildings form part of a common design, the great portico of the Thersilion facing the orchestra of the theatre. As a consequence of this arrangement, the plan of the theatre is abnormal. The auditorium has as its lowest row of seats a set of "thrones" or ornamental benches, which, as well as the gutter in front, were dedicated by a certain Antiochus; the orchestra is about 100 feet in diameter; and in place of the western parados is a closed room called the Scenotheca. The chief peculiarity, however, lies in the great portico already mentioned, which has its base about 4 feet 6 inches above the level of the orchestra. It was much too lofty to serve as a proscenium; yet, if a proscenium of the ordinary Greek type were erected in front, it would hide the lower part of the columns. Such a proscenium was actually erected in later times; and beneath it were the foundations for an earlier wooden proscenium, which was probably erected only when required. In later times steps were added, leading from the base of the portico to the level of the orchestra. The theatre was probably used, like the theatre at Athens, for political assemblies; but the adjoining Thersilion provided covered accommodation for the Arcadian ten thousand in wet weather. It is a building unique in plan, sloping up from the centre towards all sides like a theatre. The roof was supported by columns that were placed in lines radiating from the centre, so as to obscure as little as possible the view of an orator in this position from all parts of the building; there were two entrances in each side. It needs but a little imagination to appreciate the public buildings of Megalopolis as a splendid and unique example of federal and municipal architecture on a scale worthy of the principles which they represented.

See *Excavations at Megalopolis* (E. A. Gardner, W. Loring, G. C. Richards, W. J. Woodhouse; Architecture, by R. W. Schultz).—Supplementary Paper issued by the Society for the Promotion of Hellenic Studies, 1892; *Journal of Hellenic Studies*, xiii. p. 328, A. G. Bather; p. 319, E. F. Benson ("Thersilion"); 1898, p. 15, J. B. Bury ("Double City"); Dörpfeld ("Das Griechische Theater"); Puchstein, "Griechische Bühne" (Theatre). (E. GR.)

Meiderich, a commune of Prussia, in the Rhine province, $2\frac{1}{2}$ miles north-east of Ruhrort, whose harbour is in great part within its confines. Large iron and steel works, coal-mines, saw-mills, brick-works, machine-shops, and rope-walks furnish the principal occupations of the inhabitants. Population (1885), 16,105; (1900), 33,684.

Meiktila, a division and district in Upper Burma. The division includes the districts of Meiktila, Kyauksè, Yamèthin, and Myingyan, with a total area of 10,854 square miles, and a population of (1891) 902,370, and (1901) 994,432, showing an increase of 10.2 per cent., and giving a density of 91 inhabitants to the square mile. There were 3573 villages in 1898-99, paying a revenue of Rs.23,23,193. All but a small portion of the division lies in the so-called rainless district or dry zone, and the bulk of the cultivation is dependent on irrigation.

MEIKTILA DISTRICT is the most easterly of the districts in the dry zone, and has an area of 2178 square miles. It lies between Kyauksè, Myingyan, Yamèthin, and on the east touches the Shan States. The general character of the district is that of a slightly undulating plain, the gentle slopes of which are composed of black "cotton" soil and are somewhat arid. The only hills above 300 feet are on the slopes of the Shan hills. The lake is the chief feature of the district. It is artificial, and according to Burmese legend was begun 2400 years ago by the grandfather of the Buddha Gautama. It is 7 miles long, averages half a mile broad, and covers an area of $3\frac{1}{2}$ square

miles. Its depth is considerable, and with the Minhla and other connected lakes it irrigates a large extent of country.

There are small forest reserves, chiefly of cutch, in the district. Large numbers of cattle are bred. The chief agricultural products are, in their order, rice, sesamum, cotton, peas, maize, millet, and grain. The population of the district was (1891) 206,794; and (1901) 252,702, which gives an average of 116 to the square mile. Famines in 1891, 1895, and 1896 led to considerable emigration. Many families have returned, but the population is thought to have decreased. The climate is healthy except in the sub-montane townships. The temperature rises to 100° and over between the months of March and June, and the mean minimum in January is about 61°. The rainfall is very uncertain. The highest recorded has been 36.79 inches in 1893, and the lowest 25.59 in 1891. The district has the name of being the healthiest in Upper Burma. There were 1066 villages in 1898-99, paying Rs.4,67,190 revenue. The vast majority of the population are Buddhists. The headquarters town, MEIKTILA, stands on the banks of the lake. It had a population of 4685 in 1891. A wing of a British regiment is stationed here. A branch railway connects it at Thazi station with the Rangoon-Mandalay line, and continues westward to its terminus on the Irrawaddy at Myingyan.

Meilhac, Henri (1831-1897), French dramatist, was born in Paris in 1831, and while still a young man began writing fanciful articles for the newspapers and *vaudevilles* for the theatres, in a vivacious *boulevardier* spirit which brought him to the front. About 1860 he met Ludovic Halévy, and the two began a system of collaboration in writing for the stage which lasted for twenty years. An account of their work is given under HALÉVY. Meilhac wrote a few pieces also with lesser collaborators. In 1888 he was elected to the Academy. He died at Paris in 1897.

Meiningen, a town of Germany, capital of the duchy of Saxe-Meiningen, on the right bank of the Werra, embowered in forests, 39 miles south of Eisenach by rail. In the town are the Henneberg House, with the collections of the Henneberg Antiquarian Society; an arsenal, hall of the diet, and high school (with natural history collection). The Meiningen Company of actors, which won unstinted applause for the general level of excellence it attained and the effective *tout ensemble* of its staging, was dissolved in 1890 after a career of sixteen years. A new parish church was built in 1888. Busts of Brahms (1899) and Jean Paul (who lived here in 1801-03) adorn the town. Population (1885), 11,448; (1900), 14,518.

Meissen, a town of Germany, at the influx of the Triebisch and the Meisse into the Elbe, 14 miles by rail north-west by west of the town and in the circle of Dresden, kingdom of Saxony. It has a progymnasium, a *real* school and a commercial school, and a monument to Böttger (1892). The royal porcelain manufactory employs from 700 to 800 workmen. Population (1890), 17,875; (1900), 20,123. On 1st January 1901 Cölln (11,309 in 1900), on the Elbe, was incorporated with Meissen, giving the latter a total population of 31,432.

Meissonier, Jean Louis Ernest (1815-1891), French painter, was born at Lyons on 21st February 1815. From his schooldays he showed a marked taste for painting, to which some early sketches, dated 1823, bear witness. After being placed with a druggist, he obtained leave from his parents to become an artist, and, owing to the recommendation of a painter named Potier, himself a second class Prix de Rome, he was admitted to Léon Cogniet's studio. He paid short visits to Rome and to Switzerland, and exhibited in the Salon of 1831 a picture then called "Les Bourgeois Flamands" ("Dutch Burghers"), but also known as "The Visit to the Burgomaster," subsequently purchased by Sir Richard Wallace, in whose collection (at Hertford House, London) it is, with fifteen other examples of this painter. It was the first

(Buckingham Palace.)

attempt in France in the particular *genre* which was destined to make Meissonnier famous: microscopic painting—miniature in oils. Working hard for daily bread at illustrations for the publishers—Curmer, Hetzel, and Dubocher—he also exhibited at the Salon of 1836 the “Chess Player” and the “Errand Boy.” After some not very happy attempts at religious painting, he returned, under the influence of Chenavard, to the class of work he was born to excel in, and exhibited with much success the “Game of Chess” (1841), the “Young Man playing the ‘Cello” (1842), “The Painter in his Studio” (1843), “The Guard Room,” the “Young Man looking at Drawings,” the “Game of Piquet” (1845), and the “Game of Bowls”—works which show the finish and certainty of his technique, and which assured his success. After his “Soldiers” (1848) he began “A Day in June,” which was never finished, and exhibited “A Smoker” (1849) and “Bravos” (“Les Bravi,” 1852). In 1855 he touched the highest mark of his achievement with “The Gamblers” and “The Quarrel” (“La Rixe”), which was presented by Napoleon III. to the English Court (see Plate). His triumph was sustained at the Salon of 1857, when he exhibited nine pictures and drawings; among them the “Young Man of the Time of the Regency,” “The Painter,” “The Shoeing Smith,” “The Musician,” and “A Reading at Diderot’s.” To the Salon of 1861 he sent “The Emperor at Solferino,” “A Shoeing Smith,” “A Musician,” “A Painter,” and “M. Louis Fould”; to that of 1864 another version of “The Emperor at Solferino,” and “1814” (see Plate). He subsequently exhibited “A Gamblers’ Quarrel” (1865), and “Desaix and the Army of the Rhine” (1867). Unspoiled by his success, Meissonnier continued to work with elaborate care and a scrupulous observation of nature. Some of his works, as for instance his “1807,” remained ten years in course of execution. To the great Exhibition of 1878 he contributed sixteen pictures: the portrait of Alexandre Dumas which had been seen at the Salon of 1877, “Cuirassiers of 1805,” “A Venetian Painter,” “Moreau and his Staff before Hohenlinden,” a “Portrait of a Lady,” the “Road to La Salice,” “The Two Friends,” “The Outpost of the Grand Guard,” “A Scout,” and “Dictating his Memoirs.” Thenceforward he exhibited less in the Salons, and sent his works to smaller exhibitions. Being chosen as president of the Great National Exhibition in 1883, he was represented there by such works as “The Pioneer,” “The Army of the Rhine,” “The Arrival of the Guests,” and “Saint Mark.” On 24th May 1884 an exhibition was opened at the Petit Gallery of Meissonnier’s collected works, including 146 examples. As president of the jury on painting at the Exhibition of 1889 he contributed some new pictures. In the following year the New Salon was formed (the National Society of Fine Arts), and Meissonnier was the president. He exhibited there in 1890 his picture “1807”; and in 1891, shortly after his death, his “Barricade” was displayed in the same place. A less well-known class of work than his painting is a series of etchings: “The Last Supper,” “The Skill of Vuillaume the Lute Player,” “The Little Smoker,” “The Old Smoker,” the “Preparations for a Dnel,” “Anglers,” “Troopers,” “The Reporting Sergeant,” and “Polichinelle,” in the Hertford House collection. He also tried his hand at lithography, but the prints are now scarcely to be found. Of all the painters of the century, Meissonnier was one of the most fortunate in the matter of payments. His “Cuirassiers,” now in the late duc d’Aumale’s collection at Chantilly, was bought from the artist for £10,000, sold at Brussels for £11,000, and finally resold for £16,000. Besides his *genre* portraits, he painted some others: those of “Doctor Lefevre,” of “Chenavard,” of “Vanderbilt,” of “Doctor Guyon,” and

of “Stanford.” He also collaborated with the painter Français in a picture of “The Park at St Cloud.” In 1838 Meissonnier married the sister of M. Steinheil, a painter. Meissonnier was attached by Napoleon III. to the Imperial Staff, and accompanied him during the campaign in Italy and at the beginning of the war in 1870. During the siege of Paris in 1871 he was colonel of a marching regiment. In 1840 he was awarded a third-class medal, a second-class medal in 1841, first-class medals in 1843 and 1844, and Medals of Honour at the great exhibitions. In 1846 he was appointed Knight of the Legion of Honour and promoted to the higher grades in 1856, 1867 (29th June), and 1880 (12th July), receiving the Grand Cross in 1889 (29th October). He nevertheless cherished certain ambitions which remained unfulfilled. He hoped to become a professor at the *École des Beaux Arts*, but the appointment he desired was never given to him. On various occasions, too, he aspired to be chosen deputy or made senator, but he was not elected. In 1861 he succeeded Abel de Pujol as member of the Academy of Fine Arts. On the occasion of the centenary festival in honour of Michael Angelo in 1875 he was the delegate of the Institute of France to Florence, and spoke as its representative. Meissonnier was in his day an admirable draughtsman upon wood, his illustrations to *Les Contes Rémois* (engraved by Lavoignat), to Lamartine’s *Fall of an Angel*, to *Paul and Virginia*, and to *The French painted by Themselves* being among the best known. The leading engravers and etchers of France have been engaged upon plates from the works of Meissonnier, and many of these plates command the highest esteem of collectors. Meissonnier died in Paris on 21st January 1891. His son, Jean Charles Meissonnier, also a painter, was his father’s pupil, and was admitted to the Legion of Honour in 1889.

Me Kong, or ME NAM KONG (pronounced *Kawng*), sometimes known as the Cambodia river, the great river of Indo-China, and one of the most interesting of the remarkable rivers of south-eastern Asia which have their origin in the Tibetan highlands. Rising in about 33° 17' N. and 94° 25' E., it is known as the Gergu river, and flows south-eastwards through Chinese Tibetan territories to Chiamdo, on the great east and west caravan route from China to Lhasa. At this point it is about 10,000 feet above sea-level. From here, under the name Nam Chu or Chiamdo Chu, it flows southwards through little-known mountain wastes. Below Dayul in lat. 29° it is known by the Chinese name of Lantsan Kiang. For the next 300 miles of its course the Lantsan Kiang, or, as it soon becomes known among the Tai peoples inhabiting its rugged valley, the Me Kong, is very little known to us. The river flows beneath bare and rocky walls. A few scattered villages of Lusus and Mossos exist in this region: there is no trade from north to south. In 25° 18' N. the Tali-Bhamo caravan route, which has been so ably described by Colborne Baker, crosses the river by one of those iron suspension bridges which are a feature of Yunnan, at a height of 4700 feet above sea-level. From this point to Chieng or Keng Hung, the head of the old confederacy of the Sibsawng Punna or Twelve States, it is little known; the fact that it falls some 900 feet for each degree of latitude is sufficient indication of the character of the river. Between the 22nd and 23rd parallels the Burma Yunnan railway, which is being pushed up

through the Shan States, will cross into Chinese territory. Under the provisions of the Anglo-French agreement of January 1896, from the Chinese frontier southwards to the mouth of the Nam Huok the Me Kong forms the frontier between the British Shan States on the west and the territories acquired from Siam by France in 1893. By the treaty of 1893, from that point southwards to about 13° 30' N. it is also the frontier between French Indo-China and Siam, and a special zone extends 25 kilometres inland from the right bank, within which the Siamese Government agreed not to construct any fortified port or maintain any armed force. Below the Siamese Shan town of Chieng Sen the river takes its first great easterly bend to Luang Prabang, being joined by some rather important tributaries. This portion of the river is considerably obstructed by rapids. The country is mountainous, and the vegetation at the lower heights begins to assume a thoroughly tropical aspect. From Luang Prabang the river cuts its way southwards for two degrees through a lonely jungle country among fast-receding hills of low elevation. From Chieng Kan the river again turns eastwards along the 18th parallel, forcing its way through one of the most serious rapid-barriers with which the native navigator has to contend, receiving some important tributaries from the highlands of Tung Chieng Kum and Chieng Kwang, the finest country in Indo-China. In 104° E. the river resumes a southerly course through a country but thinly peopled. At Kemarat (16° N.) the fourth serious rapid-barrier occurs, some 60 miles in length, and the last at Kawng in 14° N. From here to its outfall in the China Sea the great river winds for some 400 miles through the French territories of Cambodia and Cochin China, and to its annual overflow these countries owe the extraordinary fertility of their soil. The uselessness of this great river as a commercial highway has been amply demonstrated, and it is noticeable that, with the exception of Luang Prabang and Pnompenh, there is not a single populous town along the whole 2000 miles of its stormy course.

Melanesia.—In 1880 this insular region was almost a "No Man's Land," but has since been entirely partitioned between the Netherlands, Great Britain, Germany, and France, as shown in the subjoined table. A change of nomenclature has also been introduced in the insular section of the German possessions in Melanesia. But protests have been raised against these innovations, as contrary to all precedent and international etiquette, while the new names, although now figuring on many maps, have not yet been officially adopted. The chief group affected is the New Britain archipelago, which thus becomes the Bismarck archipelago; the several members of the group—New Britain, New Ireland, and Duke of York—also becoming Neu Pommern, Neu Mecklenburg, and Neu Lauenburg respectively. It should also be noticed that the section of New Guinea assigned to Germany takes the official designation of Kaiser Wilhelm's Land. Of the

Solomon group, which by previous treaties had been distributed in nearly equal parts between Germany and Great Britain, the former Power retains only the northern island of Bougainville, having ceded to Great Britain the two large islands of Choiseul and Ysabel by the convention of November 1899. Consequently, the parting line between the British and German possessions in the western Pacific, which formerly ran from New Guinea eastwards, and was then deflected in the Solomon group a long way to the south, must now be shifted northwards so as to run nearly due east through Bougainville Strait, and then north-eastwards between the Gilbert and Marshall groups, but so as to leave Ongtong-Java to Germany.

Political Divisions of Melanesia (1900)

	Area in sq. miles.	Pop. (est.)
<i>Dutch Possessions</i> —		
West New Guinea	152,000	240,000
<i>German Possessions</i> —		
North-East New Guinea (Kaiser Wilhelm's Land)	72,000	110,000
New Britain (Bismarck) and Admiralty Archipelagos	28,000	180,000
Bougainville	6,000	(?) 10,000
<i>British Possessions</i> —		
South-East New Guinea, with the D'Entrecasteaux and Louisiade groups	90,540	...
Solomon group (except Bougainville)	20,000	200,000
Santa Cruz and Banks groups	950	9,000
Fiji with Rotuma	8,000	122,000
<i>French Possessions</i> —		
New Caledonia and Loyalties	7,630	51,000
<i>Anglo-French Dual Control</i> —		
New Hebrides	8,000	70,000
Total Melanesia	393,120	992,000

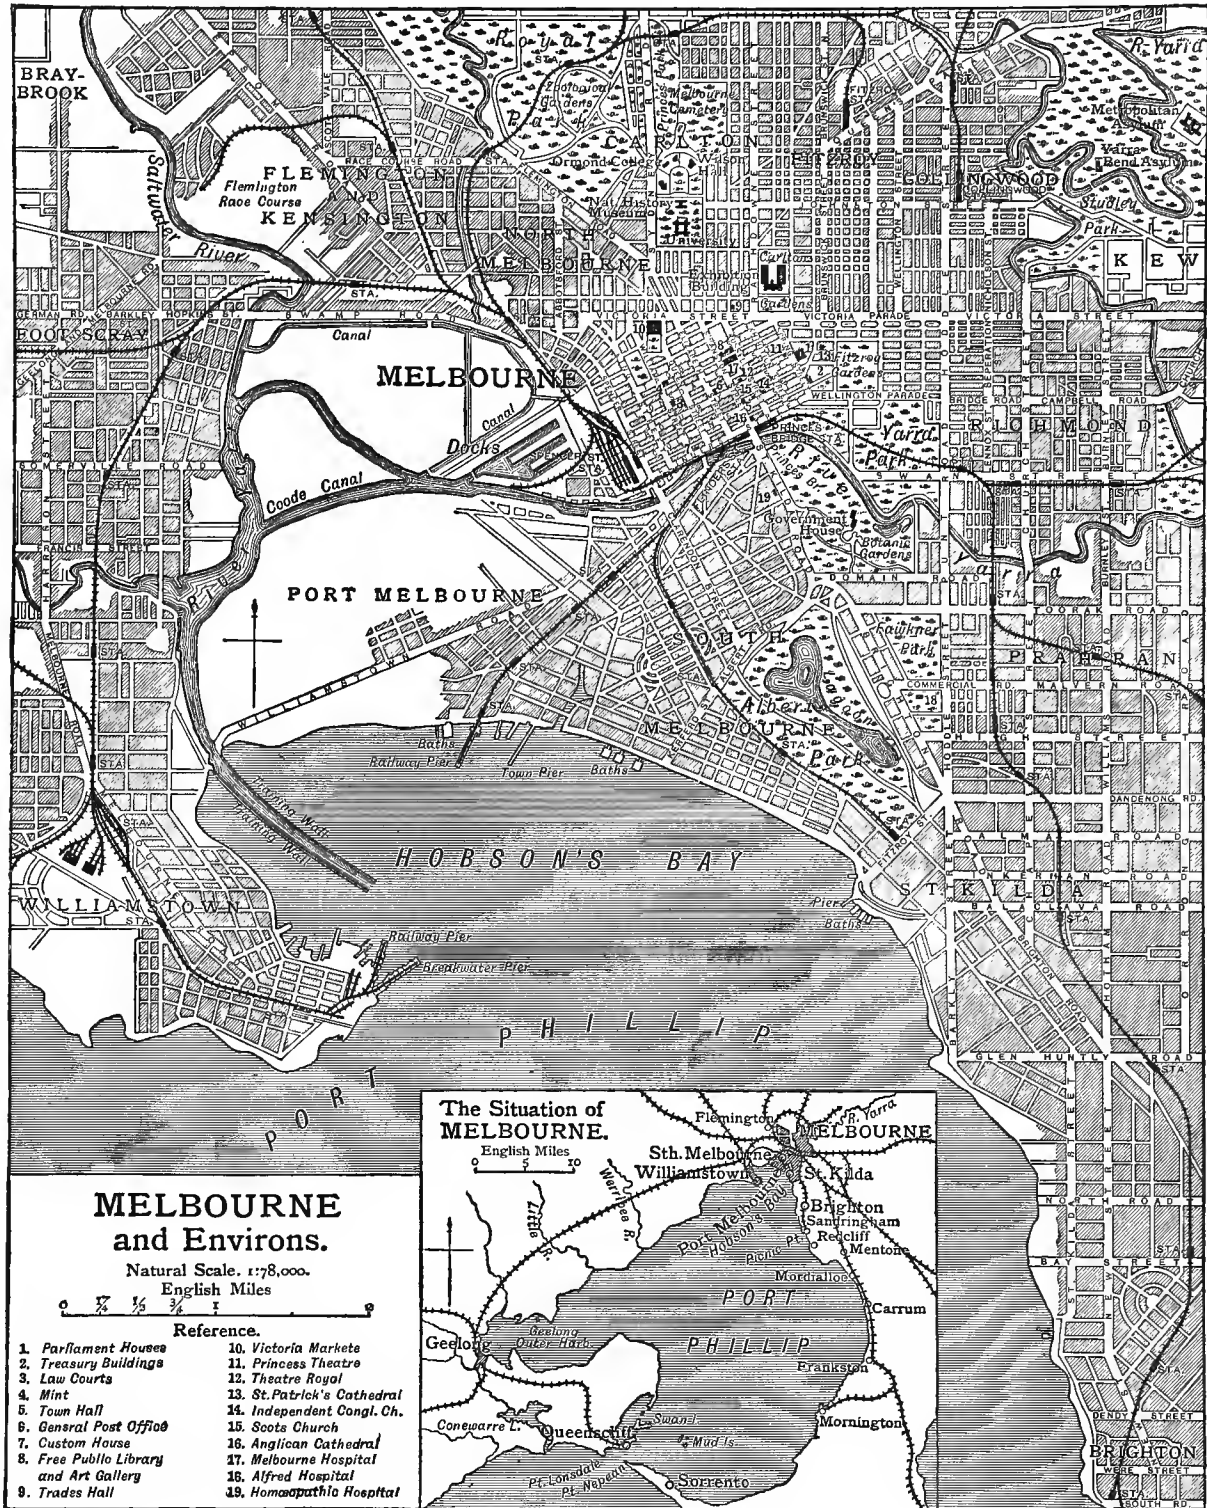

Dutch New Guinea, which comprises the western half of the island as far as a conventional line coinciding with 1410 E., is dependent on the Residency of Ternate, in the Moluccas. Kaiser Wilhelm's Land was declared a German protectorate in 1884, and since 1896 the territory has been entrusted for administrative and general purposes to the German New Guinea Company, which has also taken charge of the other German possessions in Melanesia and the Pacific Ocean. Over the New Britain archipelago and neighbouring islands a German protectorate was proclaimed in 1884. (For these and British New Guinea see NEW GUINEA. For the British Solomon Islands see SOLOMON ISLANDS. For Anglo-French Melanesia see NEW HEBRIDES. For FIJI and NEW CALEDONIA see the respective articles.)

(A. H. K.)

Melbourne, the capital of the state of Victoria, and the most populous city in Australia, situated at the head of the large bay of Port Phillip, on its northern bend, known as Hobson's Bay, about 500 miles south-west of Sydney by land and 770 by sea, the position of the observatory being 37° 49' 53" S. and 144° 58' 32" E. The entrance to Port Phillip is narrow, and a bar, called "The Rip," occupies the entrance. Within the port there are a number of suburbs on either side, such as Sorrento and Queenscliff, at the Heads, and then Mentone, Carrum, Mordialloc, Frankston, Redcliff, Picnic Point, Brighton, and St Kilda. Then the busy wharfs of Port Melbourne and Williamstown are reached. Port Melbourne (formerly known as Sandridge) is one of the most important of the shipping suburbs of Hobson's Bay, as the northern end of Port Phillip is called. It is connected with the city by railway and by cable tram, and besides its busy piers, it is a large manufacturing centre. On the opposite side of the bay to Port Melbourne is Williamstown.

Here the deep-sea mail liners are berthed beside the long piers, upon which a railway runs connecting the wharf with the city. The river Yarra, which runs into Hobson's Bay, is a winding narrow stream which has, by means of a system of canals and by dredging, been made navigable right into the heart of Melbourne for large

Walker & Cockerell sc.

steamers. Navigation for large vessels ends at the Falls Bridge, but above that bridge the river is devoted to rowing and pleasure boats. The port of Melbourne is under the control of a Harbour Trust, established in 1877, which has borrowed over £2,000,000 for the improvement

of the port, for constructing canals, dredging, and otherwise overcoming the natural disadvantages in the way of the safe navigation of the river and port.

The city proper is built upon long undulating hills, rising from a shallow valley, once occupied by a small but

densely-wooded stream running into the river Yarra. This is now the site of Elizabeth Street, one of the principal streets of Melbourne. The original plan appears to have been to construct alternately wide and narrow streets running parallel with the river, the narrow streets to give access to the big business houses which would, it was foreseen, be built on the frontages of the main streets. The plan miscarried, for city space grew so valuable that large stores and business establishments have been erected in these lanes. The main streets are 99 feet wide, and the lanes or "little" streets somewhat less than half that width. On the crown of the eastern hill stand the Parliament Houses, a massive square building, with a pillared façade to which broad steps lead up. This building is as yet unfinished, lacking the central tower. Within are the two legislative chambers—the assembly and the council. There are a fine library of reference for members, dining-rooms, billiard-room, committee-room, Speaker's room, and spacious well-kept grounds at the back of the building. Most of the streets are paved with hardwood blocks, and the main streets are traversed by cable trams, which radiate in all directions. The footpaths are broad and well paved, the streets are well lighted, and tree-planting has in many parts been successfully carried on. The public buildings and business houses are generally fine architecturally. At the top of Collins Street are the Treasury Buildings, a splendid block in brown freestone. A little farther on is St Patrick's Roman Catholic Cathedral, built of hard bluestone, the sombre appearance of which detracts somewhat from the architectural beauty of the structure. There are two other churches in Collins Street, viz., the Independent Congregational Church and the Scots Church, on opposite corners of Russell and Collins Streets. The architecture of both churches is very striking, and their commanding site on the hill makes the spire of the latter and the campanile of the former landmarks from all parts of the environs. St Paul's Cathedral (Anglican) is at the corner of Swanston Street and Flinders Street, near the Princes Bridge. The choice of a site was not a happy one, and this fine structure is hidden away on low-lying ground. The law courts are contained in a square block of buildings of classic design, with a central dome in the style of that of the Capitol at Washington. To these buildings all the courts have been removed, and are thus now under one roof. The Free Public Library and Art Gallery in Swanston Street possesses a splendid collection of volumes—considerably over 100,000 in number. It is open on week-days, and is free. In the Art Gallery the lower storey is devoted to sculpture. To the rear is the picture gallery, containing a fine collection of paintings by modern European and Australian artists. In connexion with the picture gallery there is a travelling scholarship for students, subsidized by the state, which gives a large sum annually to enable the prize-winners to pursue their studies in Paris, London, Rome, or Berlin. There are also in this building a technological museum and a collection of ethnical exhibits in the shape of Australian aboriginal and South Sea Island weapons of war, domestic utensils, and native manufactures. The Exhibition Building occupies a commanding position on a hill in Carlton Gardens, its dome being the first object which strikes the visitor approaching the city either by land or water. The building, which housed the first International Exhibition held in Victoria, was opened in 1880. It consists of a nave 500 feet long and 160 feet broad, surmounted by the dome, with two annexes 460 feet long. A good deal of the building is now used for the purposes of an aquarium and picture gallery. Government House is situated at Toorak, and is surrounded by a large domain. To the northward are Melbourne University,

Wilson Hall, and Ormond College. The General Post Office is situated at the corner of Bourke and Elizabeth Streets, a site which may be described as the very centre of the city. The Town Hall is at the corner of Collins and Swanston Streets, and possesses a large concert hall of good acoustic properties and a fine organ. The Trades Hall, Carlton, is a building of some importance, being the central meeting rooms of the trades unionists of Victoria and the focus of much political power. Melbourne University is undenominational, and was established in 1855. It received in 1898 a Government endowment of £12,750. There are three affiliated colleges, viz., Trinity (Episcopalian), Ormond (Presbyterian), and Queen's (Wesleyan). Ormond College is called after the late Frances Ormond, who contributed a sum of £82,000 towards its erection and endowment. The University Hall was built by the late Sir Samuel Wilson, after whom it is called Wilson Hall. In 1880 women were admitted to the University, and since then there have been 139 lady graduates. Behind the University is the Natural History Museum. The Mint is situated between Latrobe and Lonsdale Streets. From the opening in 1869 to the end of 1898, 20,892,650 oz. of gold had been received, valued at £82,873,785, and issued from the Mint as coin or bullion. There were 76,117,421 sovereigns and 884,564 half-sovereigns issued, besides bullion to the value of £6,310,693. Other buildings subserving useful public ends are the Melbourne Hospital, the Victoria Markets, the Custom House, the Alfred Hospital, and the Homœopathic Hospital on St Kilda Road. There are also a deaf, dumb, and blind institution, and a lunatic asylum at Yarra Bend. The most notorious feature in connexion with later developments of the city architecture was the erection of the "sky-scraper" buildings, which were the product of the "boom" period. They soar into the sunshine to a height of thirteen or fourteen storeys, with lifts, electric light, and all modern embellishments; but so far they have not been a financial success.

Melbourne is up to date in all respects, and in none more so than in its means of communication. There are in all the important buildings swift and secure elevators; the telephone service is effective, the streets and many shops are lighted by electricity. But the tramway system is the best evidence of the modernity of the city. From the central area lines of swift-moving cable trams run to all the suburban environs, such as St Kilda, Prahran, Williamstown, Port Melbourne, Richmond, South Melbourne, Fitzroy, Collingwood, Carlton, Hotham, &c. A tramway trust, representing twelve of the metropolitan municipalities, was formed under statutory authority, and was entrusted with powers to construct tramways through the streets of the municipalities concerned. The trust has leased the tramways to a private company on a 32 years' lease, which in 1900 had 17 years to run; and on the expiration of this period the councils have the power to acquire the system. Melbourne is the chief city of Australia from the point of view of population. In 1901 the population numbered 494,129; in 1891 it was 490,896. The slight advance in the decade was due to the commercial depression and bank failures, and the exodus to West Australia consequent upon the discovery of gold in that colony. The proportion of the population in Melbourne compared with that of the whole colony was, in 1871, 28-27, in 1880, 32-81, and in 1891, 43-05. These figures are noteworthy as an example of the remarkable aggregation of populations in the principal cities which is such a marked feature of Australian life. Melbourne is favoured in the matter of parks, gardens, and open spaces. The extent of the open spaces in the metropolitan area is 5329 acres, including 604 acres under the joint control of the Government and the City Council. Royal Park has an area of 600 acres. It contains in the centre a splendid Zoological Gardens, having the finest collection of wild animals and native fauna in Australia. The Botanic Gardens are situated on the banks of the river Yarra. They comprise 83 acres. But the most popular of the open-air resorts around Melbourne is the Flemington racecourse, where the "Cup" is run. This is the great Australian horse-racing event of the year, and during Cup week there is a large influx of visitors from the other states. The race takes place on the first Tuesday in November, and the average

attendance on Cup day has, for some years, been 100,000 people. The principal theatre is the Princess, in Spring Street, opposite the Parliament Houses. It is a modern house, fitted with electric light and every convenience. The Theatre Royal, in Bourke Street, is one of the oldest as it is the largest of Melbourne theatres. The drainage of the city was for many years a subject of frequent denunciation, and is still decidedly defective. Broad deep gutters, with footbridges over them, carried off the house and surface drainage. But now a comprehensive scheme of sewerage is being worked out throughout the city and suburbs, and in time even in point of drainage Melbourne will rank as a modern city. The city is supplied with water from the Yan Yean water-works, an artificial lake at the foot of the Plenty Ranges, nearly 19 miles away. From thence the water has been brought into the city and suburbs at a cost of £3,877,000. The Water and Sewerage Board, which manages this scheme, has a revenue of £1,251,000 per annum. Melbourne was constituted a municipality in 1842. The value of rateable property, which grew enormously after the incorporation of the city, has declined since the year 1891. In that year, according to *The Seven Colonies of Australasia*, the annual value of rateable property was £6,533,717, and the capital value £89,930,287. In 1898 the annual value was only £3,973,357, and the capital value £60,626,915. However, the comparative position of Melbourne is still important. "The annual value of Melbourne," says the authority quoted above, "is only surpassed by London, and to a small extent by Glasgow, in the British dominions." The city is governed municipally by a council consisting of 24 aldermen, presided over by a mayor, and is divided into seven wards. For parliamentary purposes Melbourne is divided into 25 electorates, returning 30 members.

The suburbs are important communities in themselves, and are thickly populated. They have their separate municipal governments, and most of their town halls are fine buildings, which vie with the public buildings of Melbourne. Amongst these are the town halls of South Melbourne, Prahran, Richmond, Collingwood, and South Yarra. Amongst the most populous suburbs are Collingwood, 32,191 inhabitants; Richmond, 34,097; Prahran, 36,500; South Melbourne, 38,000; Fitzroy, 29,719; Williamstown, 13,449; St Kilda, 19,703; Brighton, 9534; Kew, 8781; Hawthorne, 20,000; Brunswick, 22,759; Essendon, 15,200; Footscray, 16,880; North Melbourne, 17,886; Port Melbourne, 11,039; Flemington and Kensington, 10,501. As a port Melbourne takes the first place as regards tonnage—though of course this is discounted by the fact that imports and exports in through liners are registered in Melbourne and swell the Melbourne tonnage, though the terminal port is Sydney. The tonnage entered and cleared in various periods was in 1881, 2,144,949 tons; in 1891, 4,362,138; and in 1899, 4,947,118 tons. The yearly movement of tonnage at Melbourne and Sydney far exceeds that of any of the ports of any other British possession, Hong-Kong and Singapore excepted. Melbourne is a great manufacturing centre, and both city and suburbs have their distinctive industries. Within the metropolitan district there were, during 1898, 1375 manufactories employing 40,021 hands, 27,694 of whom were males and 12,327 females. Details are only furnished in respect of the following industries:—

Nature of Manufactory.	No.	Average Number of Hands employed.
Tanneries, fellmongeries, and wool-washing establishments	33	972
Bacon and ham curing establishments	7	87
Butter and cheese factories, and creameries	10	167
Flour-mills	10	258
Breweries	12	680
Tobacco, cigar, and snuff manufactories	13	764
Boot factories	78	3618
Brickyards and potteries	15	652
Soap and candle works	10	360
Electric light works	7	137
Gas and coke works	7	521
Stone quarries	19	118

Melbourne cemetery is situated to the north of the city, near Princes Park, and has been used as a burial-ground since 1853. Owing to the growth of the suburban population, which has prevented the extension of this cemetery, a large necropolis has been set apart at Frankston, on the eastern shore of Hobson's Bay, at some distance from the city. Melbourne has some good monuments and statues, amongst which may be named the statue of Queen Victoria in the Parliament Houses vestibule; the statue to Sir Redmond Barry, outside the Public Library; the statue to Bourke and Wills, explorers, which was formerly at the top of Collins Street, but was removed to Spring Street to make room for the cable tram; the Gordon statue in Spring Street, which is a replica of the Gordon monument in Trafalgar Square, London; and a statue to Daniel O'Connell outside St Patrick's Cathedral. The large markets, erected at a cost of £80,000, stand in Bourke Street, and a brick market is situated in Flinders Street. There were

formerly two railway stations—the main station at Spencer Street and the Hobson's Bay Railway station, as it was then called. Since then the Hobson's Bay Company have handed over their lines to the Government, and the whole system is now managed by the railway commissioners. The Hobson's Bay line is now connected with the Spencer Street line. The Spencer Street station is not an ornate structure, being built of wood principally, but an imposing building is in contemplation to take its place. There are in Melbourne, among its numerous state schools, about thirty whose size and proportions entitle them to rank with the architectural ornaments of the city. They have each accommodation for from 200 to 2000 scholars. There are many good private schools besides. The principal defences are placed at Port Phillip Heads, and consist of batteries at Queenscliff, Point Nepean, Swan Island, Point Franklin, and the shoals in mid-channel. There is also an obsolete monitor, the *Cerberus*, which lies in Hobson's Bay. But as the state of Victoria participates in the subsidy to the Australian Imperial Defence Squadron, less reliance is now placed on the *Cerberus*, and the fleet pays several visits annually to Port Phillip. There is a large graving-dock at Williamstown, the length of which is 450 feet, and which cost £341,578. The mean temperature is 57·3°, corresponding with that of Washington in the United States, and of Madrid, Lisbon, and Messina. The mean temperature is 8° less than that of Sydney and 7° less than that of Adelaide—the result of a long series of observations being: spring, 57°; summer, 65·3°; autumn, 58·7°; winter, 49·2°. The highest recorded temperature in the shade was 117·7°, and the lowest 27°. The average rainfall over a long series of years was 25·58 inches.

Melcombe Regis. See WEYMOUTH. (J. D. F.)

Meleda, formerly MELITA (Slavonic, *Mljet*), the most southern of the larger Adriatic islands of the Austrian province of Dalmatia. It is of volcanic origin, with numerous chasms and gorges, of which the longest, the Babinopolje, connects the north and south of the island. Porto Palazzo, the principal harbour, on the north, is a port of call for tourist steamers, and contains the ruins of an ancient palace. Population, 1617.

Melegnano, formerly MARIIGNANO, a town of the province of Milan, Lombardy, Italy, 11 miles south-east of Milan by the railway to Piacenza. It has manufactures of linen, silk, clothing, and bricks, and rice-husking. It was a stronghold of Milan in her great struggle against Lodi, and is famous for the victory of Francis I. of France over the Swiss in 1515, and for the battle between the French and Austrians in 1859. Population, about 6000.

Melilla, a Spanish fortified station and penal settlement on the north coast of Morocco, to the south of Cape Tres Forcas, with a population of 5432 in 1887 and 10,201 in 1897. The civil population is not important, but there is a strong garrison to protect the place against its turbulent neighbours, the lawless Arab Riff tribes, and to keep in order the large number of convicts. The town is on a peninsula connected with the mainland and outer lines of fortifications by a rocky isthmus. There is a lighthouse on the north of the town. The Vega of Melilla extends to the south and west of the outer defences, and is watered by the Oro river, whose course has been altered behind Mount San Lorenzo to prevent this stream from flowing into the little harbour, which is only accessible to very small vessels; the roadstead outside is safe and has deep water a mile to the east of the fortress. The Moorish custom-house is on the Spanish border beyond the fort of Santa Isabel, and is the only authorized centre of trade on the Riff coast between Tetuan and the Algerian frontier. Spain has always had much trouble with the Riff tribes around Melilla, and when they besieged the town in 1893, 25,000 men had to be despatched against them.

Méline, Felix Jules (1838—), French statesman, was born at Remiremont, in the department of the Vosges, on 20th May 1838. After studying law in Paris, he practised in the Court of Appeal, and took no part in politics till the fall of the Empire. The moderate

Republican opinions which he had always held now obtained for him a post in the mayoralty of the 1st arrondissement, which in March 1871 elected him a member of the Commune. He declined, however, to sit. He had been an unsuccessful candidate for the representation of his native department, the Vosges, in the National Assembly at the general election of February 1871, but was returned at a bye-election in October of the following year. He voted consistently in support of Thiers, and in 1876 was returned for the arrondissement of Remiremont. As member of the Conseil Général of the Vosges, and founder of the Épinal journal, *Le Mémorial des Vosges*, he acquired a local influence, which, added to his gift of brilliant and incisive oratory, brought him the appointment of under-secretary for justice in the Jules Simon ministry (December 1876 to May 1877). In the Republican Chamber, returned by the elections of 1877, he remained consistently moderate, and was among those who voted against the proposal for a general amnesty. Sitting for an agricultural constituency, he now came forward as the champion of the agricultural interest, and began a campaign, conducted with signal skill, knowledge, and pertinacity, in favour of a strongly protectionist policy. His first opportunity of enunciating these views with effect came with his selection in 1880 to be one of the reporters and subsequently president of the commission on the customs tariff. In February 1883 he became Minister of Agriculture in the second Ferry cabinet, and held this post till the fall of the ministry in April 1885. It was a period of severe distress both in industry and agriculture. He carried a law to protect the French beet-sugar industry from German competition, and introduced a measure raising the duties on the importation of cereals and cattle. He also founded the order of agricultural merit. In April 1888 the presidency of the Chamber became vacant on the acceptance of the premiership by Floquet. The voting for M. Méline and M. Clémenceau was equal, and by virtue of the rule giving precedence to the senior candidate M. Méline was declared elected. His tenure of the post coincided with the height of the Boulangist agitation. The debates in the Chamber were marked by an unprecedented violence, with which he proved unable to cope. It was felt that he did not wield the authority of his predecessor, Floquet, by whom he was replaced in the new Chamber of 1889. A staunch Republican, he was one of the most prominent opponents of Boulanger, and on the fall of the Floquet cabinet in February 1889 was entrusted with the formation of a new ministry, but was forced to abandon the attempt. As president of the commission on the tariff, he succeeded during the session of 1891 in inducing first the commission and then the Chamber to replace the existing system of commercial treaties by a uniform tariff of a strongly protective character, especially on articles of agricultural produce. On the fall of the Ribot ministry in March 1893, and again on the fall of the Dupuy ministry in November, he was summoned by the President, but was unable to effect a working combination. In the same year he was elected to succeed Jules Ferry as president of the Conseil Général of the Vosges. In December 1894 he again stood for the presidency of the Chamber, but was defeated by the Radical candidate, M. Brisson. On the resignation of the Bourgeois cabinet, M. Méline formed a new administration (30th April 1896), in which he himself took the portfolio of agriculture. The most urgent question that confronted him was the conflict between the Chamber and the Senate, which had caused the downfall of his Radical predecessor. M. Méline's declaration stated that while the Chamber of Deputies, as elected by direct universal suffrage, had a preponderating influence on politics, it was impossible to legislate and govern with-

out the co-operation of the Senate. This declaration, fiercely attacked by the Radicals, was carried by the help of the Right, on whom the Méline ministry found itself more and more dependent. Another pressing question was that of financial reform. M. Méline abandoned the unpopular Radical project of a tax on the French *rente*, and proposed an income-tax designed to redress the balance of taxation in favour of real property, and thus to foster the greatest of French interests—agriculture. But the opposition prevented the Government from making any substantial progress with its financial measures either in this or in the following session. The Méline ministry, however, derived fresh strength from the success of its foreign policy. The premier played a prominent part in the splendid reception accorded to the Tsar in October 1896, and during the return visit of President Faure in August 1897 reaped the credit of the most brilliant achievement of French diplomacy under the Third Republic—the public proclamation of the alliance between France and Russia. The remainder of his term of office was overshadowed by the Dreyfus case. M. Méline maintained that the verdict of the court-martial could not be revised by the Government; he prosecuted M. Zola for his attack on that tribunal, and in the debates raised by M. Zola's condemnation declared that the matter was *chose jugée*, and that there was no longer a Dreyfus case or a Zola case. The Chamber ordered by 471 votes to 40 that this speech should be posted up throughout France. His protectionist policy was severely tried by the high price of wheat in the spring of 1898. He was at last forced to decree a temporary suspension of the duty. Immediately after this the general election took place. Though the balance of parties remained nominally unchanged, the new Chamber at once proved itself hostile to M. Méline's policy of alliance with the Right. On 14th June, after passing a vote of approval in the declarations of the Government, it demanded that the latter should rely on an exclusively Republican majority. M. Méline thereupon resigned. He stood as the candidate of the Right at the Presidential election of February 1899, but received only 279 votes, against 483 cast for M. Loubet. He was afterwards the most prominent opponent of the Waldeck-Rousseau cabinet, attacking especially the policy of conciliating the Socialists by the inclusion of a Socialist, M. Millerand, as minister of commerce.

Melitopol, a district town of Russia, government of Taurida, 151 miles by rail north-east of Simpheropol, on the Molochnaya river. Till 1841 it was a small village (Novo-Alexandrovskaya), but has grown owing to its important fairs. It has two gymnasia, for boys and girls. Population (1897), 15,120.

Melrose, a police burgh of Roxburghshire, Scotland, on the river Tweed, 37¼ miles south-east by south of Edinburgh by rail. There is a market cross of date 1642, a public hall, and an institute containing library and recreation rooms. A hydropathic establishment is adjacent, and two miles west stands Abbotsford, the mansion built by Sir Walter Scott. Population (1881), 1550; (1901), 2195. The parish formerly contained part of the burgh of Galashiels, but that part was transferred to the parish of Galashiels in 1891.

Melrose, a city of Middlesex county, Massachusetts, U.S.A., on a branch of the Boston and Maine railroad, in the eastern part of the state, 7 miles north of Boston, of which it is a suburb. Its area of 6 square miles is broken and hilly, and the street plan is irregular. It has extensive and varied manufactures, with (in 1900) a capital of \$3,296,048, products valued at \$3,945,580, and 1428

hands. Population (1890), 8519; (1900), 12,962, of whom 2924 were foreign-born and 130 were negroes.

Melton Mowbray, market town and parish in the Melton parliamentary division of Leicestershire, England, on the river Wreake, 14 miles north-east of Leicester by rail. St. Mary's peal of ten bells is played by a carillon machine. The Colles Memorial Church Institute was erected in 1890, and a new cemetery of six acres opened in 1893. Three blast furnaces have been erected in the neighbouring parish of Asfordby for the smelting of the abundant supply of iron ore in the district. Population (1891), 6392; (1901), 7454.

Melville, Herman (1819–1891), American author, was born in New York City on the 1st of August 1819. He shipped as a cabin-boy at the age of eighteen, thus being enabled to make his first visit to England, and at twenty-two sailed for a long whaling cruise in the Pacific. After a year and a half of this experience he deserted his ship at the Marquesas Islands, on account of the cruelty of the captain; was captured by cannibals on the island of Nukahiva, and detained, without hardship, four months; was rescued by the crew of an Australian vessel, which he joined, and two years later reached New York. Thereafter, with the exception of a passenger voyage around the world in 1860, Melville remained in the United States, devoting himself to literature—though for a considerable period (1866–85) he held a post in the New York custom-house—and being perhaps Hawthorne's most intimate friend among the literary men of America. His writings are numerous, and of varying merit; his verse, patriotic and other, is quite forgotten; and his works of fiction and of travel are of irregular execution. Nevertheless, few authors have been enabled so freely to introduce romantic personal experiences into their books: in his first work, *Typee: A Peep at Polynesian Life, or Four Months' Residence in a Valley of the Marquesas* (1846), he described his escape from the cannibals; while in *Omoo, a Narrative of Adventures in the South Seas* (1847), *White Jacket, or The World in a Man-of-War* (1850), and especially *Moby Dick, or The Whale* (1851), he portrayed seafaring life and character with vigour and originality, and from a personal knowledge equal to that of Cooper, Marryat, or Clark Russell. The experiences of sailor-life in fore-castle or on deck, in storm and in sunshine, in pursuit of the whale or in danger of capture by savages, as narrated by Melville in his chief works, have never ceased to interest a limited yet loyal public of readers in America and England. But these stirring records of adventure were accompanied by other tales so turgid, eccentric, opinionative, and loosely written as to seem the work of another author. Melville was the product of a period in American literature when the fiction written by writers below Irving, Poe, and Hawthorne was measured by humble artistic standards. He died in New York on the 28th of September 1891. (C. F. R.)

Memel, a seaport town of Prussia, province of East Prussia, near the northern extremity of the Kurisches Haff, 91 miles by rail north by east of Königsberg *vid* Tilsit. It is the centre of the timber-exporting trade, and one of the chief seaports for the products of Lithuania. There is an average depth of 22 feet on the bar. The total value of the exports increased from £1,082,150 in 1893 to £1,484,550 in 1899, about 65 per cent. of this total being for timber. The other exports are chemicals and artificial manure, flax, linseed, and cereals. The imports, principally timber, increased from £1,236,500 in 1893 to £1,712,800 in 1899. The port was cleared in 1898 by

748 vessels of 267,360 tons. Several fresh industries have been started, *e.g.*, cellulose factories, chemical works, iron-foundries, and shipbuilding yards. The town is adorned by a bronze statue of the Emperor William I. (1896). Population (1885), 18,748; (1900), 20,174.

Memphis, a city of Tennessee, U.S.A., capital of Shelby county, and the first city in population in the state. It is situated on the east bank of the Mississippi, in the south-western part of the state, at an elevation (at the depôt of the Louisville and Nashville railroad) of 227 feet. The city is divided into twenty-two wards, and no fewer than ten railways centre in it. These, with the river, which is navigable for large vessels at all stages of water, make it one of the most important centres of internal commerce. It is connected with West Memphis, on the opposite side of the river, by a steel cantilever bridge. Memphis has large and rapidly increasing manufacturing interests. In 1900 it had 658 manufacturing establishments, with a total capital of \$11,179,024. They employed 8428 hands, and the products were valued at \$17,848,530. Among these products were lumber and timber, with a value of \$3,051,181; cotton-seed oil and cake, \$2,271,313; and foundry and machine-shop products, \$1,078,713. Among its educational institutions is the Christian Brothers' College, a Roman Catholic institution, founded in 1871, which in 1898 had 13 instructors and 179 students. The assessed valuation of real and personal property in 1900, on a basis of about 60 per cent. of the full value, was \$38,211,544, and the net debt was \$3,041,966. The tax rate ranged from \$29.70 per \$1000 in some of the wards to \$36.20 in others. Memphis was rechartered as a city with its limits extended in 1891. The population in 1890, including the population of the area added when the city was rechartered the following year, was 64,495. In 1900 the population was 102,320, of whom 5110 were foreign-born and 49,910 were negroes. The death-rate in 1900 was 25.1, about one-third higher among the coloured than among the white.

Menabrea, Luigi Federico, MARQUIS OF VALDORA (1809–1896), Italian general and statesman, was born at Chambéry on 4th September 1809. After studying at the Turin Military Academy, he was in 1848 sent on a political mission to the duchies of Modena and Parma. Elected deputy, he opposed Cavour's ecclesiastical policy and recommended reconciliation between Church and State. During the war of 1859 he gained the title of marquis by his defence of Valdora, and acquired further distinction during the siege of Peschiera. In 1860 he conducted the siege of Gaeta and was appointed senator. Entering the Ricasoli Cabinet of 1861 as Minister of Public Works, he retained his portfolio until 1864 in the succeeding Farini and Minghetti Cabinets. After the war of 1866 he was chosen as Italian plenipotentiary for the negotiation of the treaty of Prague and for the transfer of Venetia to Italy. In October 1867 he succeeded Rattazzi in the premiership, and was called upon to deal with the difficult situation created by the Garibaldian invasion of the Papal States and by the catastrophe of Mentana. During his term of office the famous grist tax Bill was passed and the tobacco monopoly instituted. After his fall in December 1869 his successor, Lanza, in order to remove him from his influential position as aide-de-camp to the king, sent him to London as ambassador, where he remained until in 1882 he replaced General Cialdini at the Paris Embassy. Ten years later he definitively withdrew from public life, and died at Saint Capin on 24th May 1896. (H. W. S.)

Menado. See CELEBES.

Me Nam, or MENAM (signifying literally the "mother water" or "main river"), the "Nile" of Siam, as Turpin calls it, and the chief highway of the interior, on whose yearly rise and fall depends the whole of the rice crop of Lower Siam. Rising in the Lao, or Siamese Shan, state of Nan in 19° 35' N. and 101° 24' E., at a height of 1400 feet upon the shoulders of the mountain mass of Doi Luang, it is first known as the Nam Ngob after a village of that name. As the Nam Nan, still a mere mountain stream, it flows southwards through the state so named between high forested ranges, and, notwithstanding the frequent rapids along its course, the natives use it in their dug-outs for the transport of hill produce. From Utaradit, where it leaves the hills of the Lao country, it flows southwards through the great plain of Lower Siam, and is navigable for flat-bottomed native craft of considerable capacity. It is here known as the Nam, or Me Nam Pichai. Below Pichai the river flows through lonely tracts of forest and swamp country, the latter providing vast overflow basins for the yearly floods. Thousands of tons of fish are caught and cured here during the fall of the river after the rains. Below Pitsunalok the waters of the Me Nam Yom, the historic river of Siam, upon which two of its ancient capitals, Sawankalok and Sukotai, were situated, meander by more than one tortuous clayey channel to the main river, and combine to form the Nam Po. At Paknam Po the main western tributary comes in, the shallow, capricious Me Ping, the river of Raheng and Chieng Mai, bringing with it the waters of the Me Wang. As the chief duty-station for teak, which is floated in large quantities down all the upper branches of the river (see under CHIENG MAI), and as a place of transshipment for boats, Paknam Po is an important and growing town. From this point southwards the river winds by many channels through the richest and most densely-populated portion of Siam. About Chainat the Tachin branches off, forming the main western branch of the Me Nam, and falling into the gulf at a point about 24 miles west of the bar of the main or Bangkok river. At Ayuthia, another of the ancient capitals of Siam, the Nam Sak flows in from the north-east, an important stream affording communication with the rich tobacco district of Pechabun, and draining the western slopes of the Korat escarpment. (See SIAM.)

Menasha, a city of Winnebago county, Wisconsin, U.S.A., on the Fox river, at the foot of Lake Winnebago, in the eastern part of the state. It is on the Chicago and North-western, the Chicago, Milwaukee and St Paul, and the Wisconsin Central railways. Population (1890), 4581; (1900), 5589, of whom 1535 were foreign-born.

Mende, chief town of department Lozère, France, 252 miles south-south-east of Paris, picturesquely situated on the Lot, at an altitude of 2420 feet, and at the foot of the Mimat cliff, which rises 1000 feet above the town. The cathedral of St Peter was founded in the 14th century by Urban V., a native of the district, but the two towers, respectively 280 and 210 feet high, were added by François de la Rovère in the early part of the 16th century. Partly destroyed by the Protestants in 1580, it was rebuilt in the 17th century, and in 1874 a statue of Pope Urban V. was erected in front. A Renaissance tower of the ancient citadel now serves as the belfry of the church of the Penitents, and a 14th-century bridge crosses the Lot. The town is a convenient centre for

visitors to the gorges of the Tarn. Local institutions are a communal college, library of 12,000 volumes, hospital, and consultative chamber of agriculture. An important industry is the manufacture of serges and shallons, known as Mende stuffs, exported to Spain, Italy, and Germany. Mende grew up around the Hermitage of St Privat, partly excavated in the side of the Mimat cliff, to which the bishop retreated after the destruction of the town of Javols, and where he was subsequently slain by the Vandals, who had pursued him thither, about 408. In the 14th century the new town became the civil, as it had previously been the ecclesiastical, capital of the Gevandan district. Population (1881), 4994; (1901), 7319.

Mendeléeff, Dmitri Ivanovitch (1834—), Russian chemist, the youngest of a family of seventeen, was born at Tobolsk, Siberia, on 7th February (N.S.) 1834. After attending the gymnasium of his native place, he went to study natural science at St Petersburg, where he graduated in chemistry in 1856, subsequently becoming *privat-docent*. In 1859 he went to Heidelberg, where he started a laboratory of his own, but returning to St Petersburg in 1861, he became professor of chemistry in the Technological Institute there, and three years later succeeded to the same chair in the university. Mendeléeff's original work covers a wide range, from questions in applied chemistry, such as the origin of petroleum deposits and the application of nitro-compounds to the manufacture of smokeless powders, to the most general problems of chemical and physical theory. His name is best known for his work on the Periodic Law. He was not the first to take up this subject, for before him various chemists had traced numerical sequences among the atomic weights of some of the elements and noted connexions between them and the properties of the different substances, but it was left to him to give a full expression to the generalization, and to treat it not merely as a system of classifying the elements according to certain observed facts, but as a "law of nature" which could be relied upon to predict new facts and to disclose errors in what were supposed to be old facts. Thus in 1871 he was led by certain gaps in his tables to assert the existence of three new elements so far unknown to the chemist, and to assign them definite properties. These three he called ekaboron, ekaaluminium, and ekasilicon; and his prophecy was completely vindicated within fifteen years by the discovery of gallium by de Boisbaudran in 1871, scandium by Nilson in 1879, and germanium by Winkler in 1886. Again, in several cases he ventured to question the correctness of the "accepted atomic weights," on the ground that they did not correspond with the Periodic Law, and here also he was justified by subsequent investigation. Since his early work the periodic arrangement of the elements has engaged the attention of many chemical thinkers, and numerous variations in it and in the modes of stating it have been proposed. So far, however, no formulation has been suggested which commands universal acceptance as final, and the task still remains not only of finding a solution of certain anomalies, real or apparent, but of explaining the cause and inner meaning of the periodicities that have already been observed. Another branch of chemical theory to which Mendeléeff attaches great importance and has devoted much study is the question of such "indefinite" compounds as solutions, which he looks upon as homogeneous liquid systems of unstable dissociating compounds of the solvent with the substance dissolved, holding the opinion that they are merely an instance of ordinary definite or atomic compounds, subject to Dalton's laws. In another department of physical chemistry he has investigated the expansion of

liquids with heat, and devised a formula for its expression similar to Gay-Lussac's law of the uniformity of the expansion of gases, while so far back as 1861 he anticipated Andrews's conception of the critical temperature of gases by defining the absolute boiling-point of a substance as the temperature at which cohesion and heat of vaporization become equal to zero and the liquid changes to vapour, irrespective of the pressure and volume. Mendeléeff has written largely on chemical topics, his most widely-known book probably being the *Principles of Chemistry*, which was written in 1868-70, and has gone through many subsequent editions in various languages. For his work on the Periodic Law he was awarded in 1882, at the same time as L. Meyer, the Davy medal of the Royal Society.

Mendoza, a province in the west of the Argentine Republic, bounded on the N. by San Juan, on the E. by San Luis, on the S. by the territories of Pampa and Neuquen, and on the W. by Chile. The official area at the census of 1895 was 56,502 square miles. The population in 1869 was 65,413, and in 1895 it was 116,136. Mendoza is divided into sixteen departments. In 1895 there were 7308 farms, and 28,244 acres planted in cereals. The capital, MENDOZA, with a population in 1895 of 28,302, is 636 miles from Buenos Aires by rail, and has a national college, agricultural school, normal school, and other public institutes.

Menelek II. (SAHALA MARIEM), EMPEROR OF ABYSSINIA (1844—), son of Haëli Melicoth, king of Shoa, was born in 1844, and claimed to be a direct descendant of Solomon by the Queen of Sheba. On the death of his father in 1856 he was kept a prisoner at Gondar by Kassai, the governor, who had seized the throne under the title of Theodore III. But having succeeded in effecting his escape, he was acknowledged king of Shoa, and at once attacked the usurper. These campaigns were unsuccessful, and he turned his arms to the west, east, and south, and annexed much territory to his kingdom, still, however, maintaining his divine right to the crown of Ethiopia. After the death of Theodore in 1868 he continued to struggle against his successor, the Emperor Johannes. Being again unsuccessful, he resolved to await a more propitious occasion; so, acknowledging the supremacy of Johannes, he married his daughter to the emperor's son, the Râs Area; he was thereupon declared heir to the empire, and on his side acknowledged the Râs Area as his successor. Shortly afterwards the Râs Area died, and the Emperor Johannes was killed in a war against the Dervishes at the battle of Matama, 10th March 1889. The succession now lay between the late emperor's natural son, the Râs Mangasha, and Menelek, but the latter was elected by a large majority on 4th November, and consecrated shortly afterwards. His clemency to Mangasha, whom he compelled to submit and then made viceroy of Tigré, was ill repaid by a long series of revolts. In 1889 Menelek signed the treaty of Uccialli, but finding that its ambiguity placed his empire under Italian domination, he denounced it; and after defeating the Italians at Amb-Alaghi, he compelled them to capitulate at Adowa in February 1896, and a treaty was signed recognizing the absolute independence of Abyssinia. His French sympathies were shown in a reported official offer of treasure towards payment of the indemnity at the close of the Franco-Prussian war, and in February 1897 he concluded a commercial treaty with France in very favourable terms. The British mission under Sir Rennell Rodd in the following year was, however, cordially received, and Menelek agreed to a settlement of the Somali boundaries, to keep open to British commerce the caravan route between

Zeila and Harrar, and to prevent the transit of munitions of war to the Mahdists, whom he proclaimed enemies of Abyssinia. (See also ABYSSINIA.)

Mengtze, a district city in the south-east of the province of Yunnan, China. It was selected by the French convention of 1886 as the seat of the overland trade between Tongking and Yunnan, and opened two years later. It is situated on an elevated plateau 4580 feet above sea-level. The country round is fertile and well cultivated, and the place must have been one of considerable wealth before the Taiping rebellion, as the ruins of many fine temples attest. Population, about 12,000. A very considerable overland trade has sprung up since the opening of Mengtze. In 1898 the value of the trade was £596,748, in 1899, £854,252, and in 1900, £832,860, 54·8 per cent. of this being imports and 45·2 per cent. exports. Of the import trade Hong Kong supplied 96 per cent. and of the export trade 80 per cent., Tongking claiming the remainder. Tin (79·5 per cent.) and opium (17·7 per cent.) are the principal exports, and textiles (67 per cent.), mostly cottons, and tobacco (9·3 per cent.) are the chief of the imports. On the Tongking side this trade follows the Red river route as far as Manhao, which is distant from Mengtze about 40 miles, though the navigation of the river is attended by considerable difficulties. From Manhao the transit is by land, and is performed by coolies or pack animals. Concessions have been obtained by the French Government to build a line of railway from Tongking frontier at the town of Laokai *via* Mengtze to Yunnanfu.

Menominee, a city of Michigan, U.S.A., capital of Menominee county, on Lake Michigan, at the mouth of Menominee river, in the southern part of the Upper Peninsula, at an altitude of 595 feet. It has three railways, the Chicago and North-western, the Chicago, Milwaukee and St Paul, and the Wisconsin and Michigan. It is an important shipping point for lumber and iron ore, and has many saw and planing mills. Population (1890), 10,630; (1900), 12,818, of whom 4186 were foreign-born. The death-rate in 1900 was 14.

Menomonie, a city of Wisconsin, U.S.A., capital of Dunn county, on the Red Cedar river, in the western part of the state, at an altitude of 807 feet. It is on the Chicago, Milwaukee and St Paul, and the Chicago, St Paul, Minneapolis and Omaha railways. It has lumber and flour mills, and is an important shipping point for grain and lumber. Population (1890), 5491; (1900), 5655, of whom 1772 were foreign-born.

Menorca. See BALEARIC ISLANDS.

Mentone (Italian, *Mentone*), town, arrondissement of Nice, department of Alpes-Maritimes, France, 19 miles east-north-east of Nice by rail. The church of St Michel in the old town has been rebuilt in great part since the earthquake of 1887. A monument was erected in 1895 to commemorate the union of Mentone with France. There is a proposal to convert the Corci Valley into public gardens. In the eastern bay is the harbour, constructed in 1890. It has a depth of 24 feet, and is sheltered by a jetty 400 yards long; but although accessible to large vessels, it is frequented chiefly by those engaged in coasting trade. The distillation of various essences is an important industry, to feed which the double violet and a particular species of orange are cultivated. The culture of the vine, for some time abandoned, has been again introduced, and yields a wine of fair quality. About 1½ miles east of the town the bridge of St Louis crosses the torrent which separates France from Italy. Population (1881), 6737; (1891), 8232; (1901), 14,913.

Menzel, Adolph Friedrich Erdmann von (1815—), German artist, was born at Breslau on 8th December 1815. His father was at the head of a school for girls, and intended to educate his son as a professor; but he would not thwart his taste for art. Left an orphan in 1832, Menzel found himself called upon to maintain his family. In 1833 Sachse of Berlin published his first work, an album of pen-and-ink drawings reproduced on stone, to illustrate Goethe's little poem, "Künstler's Erdenwallen." He executed lithographs in the same manner to illustrate *Denkwürdigkeiten aus der brandenburgisch-preussischen Geschichte*, pp. 834-36; "The Five Senses" and "The Prayer," as well as diplomas for various corporations and societies. From 1839 to 1842 he produced 400 drawings, reviving at the same time the technique of engraving on wood, to illustrate the *Geschichte Friedrichs des Grossen* ("History of Frederick the Great") by Franz Kugler. He subsequently brought out *Friedrichs des Grossen Armee in ihrer Uniformirung* ("The Uniforms of the Army under Frederick the Great"), *Soldaten Friedrichs des Grossen* ("The Soldiers of Frederick the Great") and finally, by order of the Emperor Frederick William II., he illustrated the works of Frederick the Great, *Illustrationen zu den Werken Friedrichs des Grossen*. By these works Menzel has established his claim to be considered one of the first, if not actually the first, of all the illustrators, of his day in his own line. Meanwhile Menzel had set himself to study unaided the art of painting, and he soon produced a great number and variety of pictures, always showing keen observation and honest workmanship—subjects dealing with the life and achievements of Frederick the Great ("A Concert," see Plate) and scenes of everyday modern life, such as "In the Tuileries," "The Ball Supper," and "At Confession." Among the most important of these works are "The Forge" and "The Market-place at Verona." Invited to paint "The Coronation of William I. at Koenigsberg," he produced an exact representation of the ceremony without regard to the traditions of official painting. In a curious study of Menzel (*Gaz. des Beaux Arts*, Paris, 1880) M. Duranty writes, "Though in excellent health, Menzel has a morbid love of truth." Menzel's example has been an encouragement to multitudes of his fellow-artists; and more than one who would have been no more than a pleasing painter of incident has, by his influence, been transformed into an attentive observer of the facts of nature. Among these disciples are F. Skarbina, Max Liebermann, and G. Kuhl. Menzel is one of the most interesting and most genuinely original personalities among the artists of the 19th century.

See LUDWIG PIETSCH. *A. Menzel.*—"A. Menzel," *Knackfuss Collection*, No. 7.

Menzelinsk, a district town of Russia, government of Ufa, 181 miles north-west of the town of Ufa, and 10 miles from the left bank of the Kama. Its fair is one of the most important in the southern Ural region, goods, chiefly cattle, hides, furs, grain, tea, manufactured articles, crockery, &c., being sold to the annual value of £400,000 to £500,000. Population (1897), 7542.

Meran, a favourite health resort and the capital of a district in South Tirol, Austria. The population in 1890 was 7176, or, with the adjoining communes of Obermais and Untermais, 13,201; and in 1900, 9284, and with adjoining communes, 17,951. It is Catholic, and chiefly German. The public buildings now include a Protestant church. The annual number of visitors and patients is about 10,000.

Mercantile, or Commercial, Agencies, in America, are organizations designed to collect, record, and distribute to regular clients information relative to

the standing of commercial firms. In Great Britain and some European countries trade protective societies, composed of merchants and tradesmen, are formed for the promotion of trade, and members exchange information regarding the standing of business houses. These societies had their origin in the associations formed in the middle of the 19th century for the purpose of disseminating information regarding bankruptcies, assignments, and bills of sale. The mercantile agency in the United States is a much more comprehensive organization and covers a wider field. It came into existence after the great financial disaster of 1837, when all commerce was prostrate. Trade in the United States had become scattered over a wide territory. Communication was slow and the town merchant was without adequate information as to the standing of many business men seeking credit. Such information as could be gathered was collected individually by correspondence and in other ways. Some large houses, whose business justified the expense, employed travelling agents to report on debtors and collect moneys due. At best the information obtained was very meagre and by no means trustworthy. Undoubtedly the severity of the collapse of 1837 was due in part to the insufficiency of this information. New York merchants, who had suffered so severely, determined to organize a headquarters where reports regarding the standing of customers could be exchanged. Lewis Tappan, a man well known in business circles at that time, undertook the work. This led to the establishment of the Mercantile Agency in New York in 1841, the first organization of its kind. The system has been wonderfully developed and extended since. It now includes the whole North American continent. The territory has been completely divided into districts with more than 150 branch offices. Branches are also established in all the leading capitals of the world. Hundreds of reporters, correspondents, and clerks are employed constantly in gathering and recording information relative to the formation of firms and corporations, of persons identified with such firms and corporations or engaged themselves in mercantile pursuits; their financial resources; their past business training and present business relations, and other facts having a direct bearing on their standing and credit. This information is not wholly *ex parte*; where circumstances warrant it, reliance is placed on statements made by parties concerned, and the making of such statements is encouraged. Financial responsibility is not the whole question to be determined by the grantor of credit, but the capacity of the grantee to transact business, his opportunities and the competition he is compelled to meet. Credit is an essential to commerce conducted on enormously broad lines, and those lines are constantly extending. The granting of credit is as much a problem in the mercantile world to-day as it was when mercantile agencies were first known. Improvement in means of communication by post and with the aid of the electric current, and the perfection of the art of printing, have made possible immense strides in mercantile agency business. Instead of curtailing the usefulness of the system, they have been the means of expanding enormously trade possibilities, thereby increasing in greater ratio the necessity for quick and accurate sources of information. Agency records are subject to constant revision, and through the improved methods of communication are constantly at the service of clients at distant points. A rating book is issued quarterly, in which the names of a million and a half separate and distinct mercantile firms are given, classified by states, cities, and towns, and arranged alphabetically, with a key showing estimated capital and credit rating, explanatory classification symbols, state maps showing routes, and

"A CONCERT OF FREDERICK THE GREAT." By ADOLPH MENZEL.
(By permission of the Berlin Photographische Co.)

much information of value to mercantile firms. Weekly correction sheets are issued. There are two large agencies in the United States—the Mercantile Agency, R. G. Dun and Co., established 1841, and the Bradstreet Company. There are a number of small agencies, but in the main they are confined to single trades.

Mercury.—The world's production of mercury for 1899 was 3775 metric tons, of which Spain produced 1357, the United States 993, Austria 536, Russia 360, Mexico 324, and Italy 205 metric tons. The American product comes almost entirely from California. Mercury is known to occur in South America, China, Japan, Australia, New Zealand, the East and West Indies, and Iceland. Mercury occurs in formations of all ages from the Archæan to the Quaternary, and it has been found in both sedimentary and eruptive rocks of the most varied character, *e.g.*, conglomerates, sandstones, shales, limestones, quartzites, slates, serpentines, crystalline schists, and eruptive rocks from the most acid to the most basic. It appears that nearly all known deposits occur along lines of continental uplift, where active shearing of the formations has occurred. Large deposits are seldom found in eruptive rocks, but generally near such formations or near active or extinct hot springs. The deposits are of many types, simple fissure veins being less usual than compound, reticulated, or linked veins. Segregations and impregnations are very common. The form of the deposit seems to depend chiefly on the physical properties and structure of the enclosing rocks and the nature of the fissure systems that result from their disturbance. The principal ore is cinnabar, though metacinnabarite and native mercury are often abundant; the selenide, chloride, and iodide are rare. Of the associated heavy minerals, pyrite (or marcasite) is almost universal, and chalcopyrite, tetrahedrite, blende, and realgar are frequent. Many deposits contain traces of gold and silver, and some deposits, as the Mercur in Utah, are more valuable for their gold than their mercury content. The usual gangue-forming minerals are quartz, dolomite, calcite, barite, fluorspar, and various zeolites. Some form of bituminous matter is one of the most universal and intimate associates of cinnabar. Formerly quicksilver deposits were supposed to be formed by sublimation, but a careful study of the California occurrences convinced the writer as early as 1875 that this was unlikely, and that deposition from hot alkaline sulphide solutions was more probable. By treating the black mercuric sulphide with such solutions, hot and under pressure, he succeeded in producing artificial cinnabar and metacinnabarite. He also showed that the mineral water at the New Almaden mines, when charged with sulphydric acid and heated under pressure, was capable of effecting the same change, and that this method of production agreed better with all the facts than the sublimation theory. (See "Genesis of Cinnabar Deposits," *Am. Jour. Science*, vol. xvii. p. 453.) The investigations of Dr G. F. Becker on the "Quicksilver Deposits of the Pacific" (*U.S. Geol. Survey*, Mon. xiii. 1888) established the correctness of these views beyond doubt.

With the exception of the massive deposits of Almaden in Spain and a few of those in California and Idria, cinnabar occurs in forms so disseminated as to make its mining very expensive. Rude hand-sorting of the ores is usually practised. Wet concentration has not been successful, because it necessitates ore crushing and extensive slime losses of the brittle cinnabar. As a rule low-grade ores can be roasted directly with less loss and expense. At Almaden in Spain the ores average from 5 to 7 per cent., but in other parts of the world much poorer ores have to be treated. In California, in spite of the high cost of labour, improved furnaces enable ores containing not more than one-half per cent. to be mined and roasted at a profit. Distillation with lime in retorts, being applicable to rich ores only, is no longer used. The first improvement was the roasting of the coarse ores in discontinuous furnaces; these were

first made continuous at Idria in Austria. The most successful of these continuous furnaces was a modification of Count Rumford's continuous lime-kiln. This furnace was introduced at New Almaden by Mr J. B. Randol, the author of many improvements in the metallurgy of mercury. The success of the continuous coarse-ore furnace at New Almaden led Mr Randol to attempt the continuous treatment of fine ores also, and the Huettner and Scott continuous fine-ore furnace, which was the result of these experiments, solved the problem completely. It contains several vertical shafts in which the descending ore is retarded at will by inclined shelving, which causes it to be exposed to the flames as long as may be necessary to roast it thoroughly. The time of treatment is determined by the rapidity with which the roasted ore is withdrawn at the bottom. Several similar furnaces are in use, as the Knox and Osborne, the Livermore, and the Cormak-Spirek. The fumes from the roasting furnaces are received in masonry chambers, usually provided with water-cooled pipes; from these it passes through earthenware pipes, and finally through others of wood and glass. Not all the yield is in liquid mercury; much of it is entangled in masses of soot that cover the condenser walls, and this is only recovered after much labour. The conditions for effective condensation are:—(1) The furnace gases should be well oxidized, to avoid the production of an excess of soot. Gas firing would meet this requirement better than the use of wood or coal. (2) The volume of permanent gases passing through the furnace should be reduced to a minimum consistently with complete oxidation. (3) The cross-section of the condensers should be sufficient to reduce the velocity of the escaping gases, and the surface large enough for cooling and for the adhesion of condensed mercury. The latter requirement is best provided for by hanging wooden aprons in the path of the cooled gases. (4) The temperature of the escaping gases should not exceed 15° to 20° C., but cooling below this temperature would not give any adequate return for the expense. Cooling by water is quicker, but more expensive than by air. Water sprays, acting directly on the fumes, have not given good results, on account of the difficulty of recovering flowered quicksilver from the water. (5) The use of an artificial inward draught is absolutely necessary to control the operation of the furnaces and condensers and to avoid the salivation of the workmen. (6) The condenser should be easily and quickly cleaned during the operation of the furnace. (7) Both furnaces and condensers should have inclined iron plates in their foundations to prevent the infiltration of mercury. (8) There is a great need of some substance for the construction of quicksilver condensers which shall be strong enough to be made thin, be a good conductor of heat, and resistant to abrasion and the alternate action of heat and cold. It should also resist the action of mercury and warm dilute sulphuric acid, and be not too expensive. Quicksilver is best removed from the "soot," not by pressure, but by the opposite treatment. A machine in use for this purpose at New Almaden, devised by Col. von Leicht, consists of an iron bowl, perforated at the bottom, in which revolves a vertical shaft carrying a propeller blade which tosses the soot (mixed with wood ashes and a little cold oil) into the air, so that the entangled mercury is free to run out through the bottom of the bowl. The residue from which no more mercury can be extracted mechanically is returned to the roasting furnace. The losses of treatment are:—(1) Furnace loss, which is easily reduced to nothing, and (2) condenser loss, which can never be zero. The latter consists of mercury lost as vapour and as mist, and its minimum amount is determined not by the richness of the ore but by the volume of escaping gases, their velocity and temperature. The percentage of loss will be higher with a poor than a rich ore. On a 3 per cent. ore the losses need not exceed 3 or 4 per cent. ore content. On a 1 per cent. ore they will run from 5 to 10 per cent. But in poorly arranged plants under bad management they may easily be doubled or even trebled. The Huettner and Scott fine-ore furnace costs with condensers in California about \$30,000, and roasts from 30 to 45 tons of ore (from 2½ inches to dust) in 24 hours at a cost of from \$1 to \$0.62 per ton.

For details see "Mines and Works of Almaden in Spain," by M. Kuss, translated from *Ann. des Mines* by S. B. CHRISTY. San Francisco, 1879; and "Imperial Quicksilver Works, Idria in Krain [Carniola]," translated by S. B. CHRISTY. San Francisco, 1884. Also the following from the *Trans. Am. Ins. Min. Eng.*:—T. EGLESTON. "Mercury in North California," vol. iii. p. 273.—S. B. CHRISTY. "Quicksilver Reduction and Condensation at New Almaden," vols. xlii. p. 574, xiv. p. 206.—V. SPIREK. "Quicksilver Industry of Italy," *Mineral Industry*, vol. vi. p. 568. The geological occurrence of cinnabar is elaborately treated in the work of Dr Becker already cited. (S. B. C.)

Meredith, George (1828—), British novelist and poet, of mixed Irish and Welsh descent, was born in Hampshire on the 12th of February 1828. At an early age he was sent to school in Germany, where he remained until he was fifteen. During these impressionable years

he imbibed a good deal of the German spirit; and German influence, especially through the media of poetry and music, can often be traced in the cast of his thought and sentiment, as well as in the formation of his literary style. Upon his return to England he started, at his guardian's desire, upon the study of law, for which, however, he felt very little inclination, and he soon abandoned it for the more congenial sphere of literature. At the age of twenty-one he began to contribute poetry to the magazines. His early career was not without the difficulties commonly incident to the literary calling. He was engaged for some years in journalism, editing an Eastern Counties paper, for which he wrote numerous political notes and articles. During the

Austro-Italian war of 1866 he acted as special correspondent of the *Morning Post*, and, although he saw little actual fighting, he enjoyed, particularly at Venice, opportunities for a study of the Italian people which he afterwards turned to account in his novels, and especially in *Vittoria*. Towards the close of 1867, when his friend Mr John Morley paid a visit to America, Mr Meredith undertook in his absence the conduct of the *Fortnightly Review*. For many years he acted as literary adviser to the publishing firm of Chapman and Hall, in which capacity he left a reputation for being not only eminently wise in his selection of the books to be published, but both critical and encouraging to authors of promise whose works he found himself obliged to reject. Among the writers with whom he came in contact in this way were Lord Lytton ("Owen Meredith"), Mr Thomas Hardy, and Mr George Gissing, all of whom have expressed their grateful sense of his wise assistance.

He was, indeed, one of the last of the old school of "readers." Mr Meredith married twice, his first wife being a daughter of Thomas Love Peacock. She died after twelve years of married life, broken by separation. On his second marriage Mr Meredith settled at Box Hill, Surrey, close to the old inn in which Keats wrote part of *Endymion*. His second wife died 17th September 1885.

Mr Meredith's first appearance in print was in the character of a poet, and his first published poem may be found in *Chambers's Journal* for 7th July 1849. Two years later he put forth a small volume of *Poems* (1851), which, if it did not attract a large public, was at least fortunate in eliciting the praise of two judges whose opinion was of the first importance to a beginner. Tennyson was at once struck by the individual flavour of the verse, and declared of one poem, "Love in the Valley," that he could not get the lines out of his head. Charles Kingsley's eulogy was at once more public and more particular. In *Fraser's Magazine* he subjected the volume to careful consideration, praising it for richness and quaintness of tone that reminded him of Herrick,

for completeness and coherence in each separate poem, and for the animating sweetness and health of the general atmosphere. At the same time he censured the laxity of rhythm, the occasional lack of polish, and the tendency, always characteristic of Mr Meredith's poetry, to overload the description with objective details to the confusion of the principal effect. No doubt as a result of Kingsley's introduction, two poems by Mr Meredith appeared in *Fraser's Magazine* shortly afterwards; but with the exception of these, and a sonnet in the *Leader*, he did not publish anything for the next five years. In the meanwhile he was busy upon a work which was to give him a triumphant introduction to the world of letters. It was early in 1856 that the *Shaving of Shagpat* made its appearance, and, despite the fact

GEORGE MEREDITH.

(From a photograph by Frederick Hollyer of the painting by G. F. Watts.)

that the hour was particularly rich in literary production, it was at once recognized as a work of singular imagination, richness, and romance. George Eliot was one of the first to acclaim its excellence, and Dante Gabriel Rossetti was among its enthusiastic eulogists. Its success was not, perhaps, popular, but it was at least genuine, and the book remains one of the most fascinating in the language. Modelled upon the *Arabian Nights*, it catches with wonderful ardour the magical atmosphere of Orientalism; through its city of "yellow domes and black cypresses, silver fountains and marble pillars," the reader wanders with all the circumstance of imaginative actuality. Mr Meredith, in casting about for a new field, was less fortunate in inspiration. It occurred to him to turn his familiarity with the life and legendary tradition of the Rhinelander into a sort of imitation of the grotesquerie of the German romanticists, and in the following year, 1857, he put forth *Farina, a Legend of Cologne*, which sought to transfer to English sympathies the spirit of German romance in the same way that *Shagpat* had handled Oriental fairy-lore. The result was less successful. The plot of *Farina* lacks fibre, its motive is insufficient, and the diverse elements of humour, serious narrative, and romance scarcely stand in proportion to one another. If, however, *Farina* lost him a little ground, the *Ordeal of Richard Feverel*, which followed in 1859, transferred Mr Meredith at once to a new sphere and to the altitude of complete success. With this novel Mr Meredith deserted the realm of fancy for that of the philosophical and psychological study of human nature, and *Richard Feverel* was the first, as it is perhaps the favourite, of those wonderful studies of motive and action which placed him at the head of contemporary novelists. The theme of this fine study is the question of a boy's education. It depicts the abortive attempt of a proud and opinionated father, hide-bound by theory and precept, to bring up his son to a perfect state of manhood through a "system" which controls all his early circumstances and represses

many of the natural and wholesome instincts and impulses of adolescence. The love scenes in *Richard Feverel* are specially fresh and full of vitality, and marked a revolution in the English treatment of clean and manly passion. In the following year Mr Meredith contributed to *Once a Week*, and in 1861 published as a book the second of his novels of modern life, *Evan Harrington*, which contains a richly humorous—occasionally almost farcical—plot, with some magnificent studies of character. A year later he produced his finest volume of poems, entitled *Modern Love, and Poems of the English Roadside, with Poems and Ballads*. A memorable attack upon the dramatic poem which gives the volume its title appeared in the *Spectator*, based upon the view that the poet had elected to treat a deep subject—psychical unfaithfulness—without himself possessing any sufficient conviction upon its issues. To this Mr Swinburne, with one of his characteristically generous impulses, replied (*Spectator*, 7th June 1862) in a spirit of fervent eulogy, pointing out that it is the part of poetry not so much to argue a thesis as to state a case, and that the subject had been treated in *Modern Love* with all the lucidity demanded by poetic convention. Some of the individual "sonnets" (of sixteen lines) into which *Modern Love* is divided are certainly worthy of being ranked with the most subtle and most intense poetic work of the 19th century.

Returning to fiction, Mr Meredith next published *Emilia in England* (1864), afterwards renamed *Sandra Belloni*. His powerful story, *Rhoda Fleming* (1865), followed soon afterwards. *Vittoria*, published in the *Fortnightly Review* in 1866, and in book form in 1867, is a sequel to *Emilia in England*. Four years later appeared *The Adventures of Harry Richmond*, in the pages of *Cornhill* (1870-71). Its successor was *Beauchamp's Career* (*Fortnightly Review*, 1874-75), the novel which Mr Meredith has privately described as his own favourite. Its hero's character is supposed to have been founded upon that of the late Admiral Maxse, Mr Meredith's brother-in-law. "The House on the Beach" and "The Case of General Opie and Lady Camper" (*New Quarterly Magazine*, 1877) were slight but glittering exercises in comedy; the next important novel was *The Egoist* (1879). In an interesting series of lectures which Mr Meredith delivered at the London Institution in 1877 his main thesis was that a man without a sense of comedy is dead to the finer issues of the spirit, and the conception of Sir Willoughby Patterne, the central figure of *The Egoist*, is an embodiment of this idea in the flesh. *The Tragic Comedians* (1880), the next of Mr Meredith's long novels, combines the spirits of comedy and tragedy in the story of the life of Ferdinand Lassalle, the German Socialist. The appearance of *Diana of the Crossways* (1885) marks an epoch in Mr Meredith's career, since it was the first of his stories to strike the general public. Its heroine was popularly identified with Sheridan's granddaughter, Mrs Norton, and the use apparently made of the well-known story of that lady's communication to *The Times* of the Cabinet secret of Peel's conversion to Free Trade had the effect of producing explicit evidence from Lord Dufferin and others that this story was untrue. However that might be, its popular acceptance gave additional interest to the novel.

Meanwhile further instalments of poems—*Poems and Lyrics of the Joy of Earth* (1883)—had struck anew the full, rich note of natural realism which is Mr Meredith's chief poetic characteristic. "The Woods of Westernmain," in particular, has a sense of the mysterious communion of man with nature unapproached by any English poets save Wordsworth and Shelley. *Ballads and Poems of Tragic Life* (1887) and *A Reading of Earth* (1888) gave further evidence of the wealth of thought and vigour of

expression which Mr Meredith brought to the making of verse. To "the general," no doubt, Mr Meredith's verse is prohibitive, or nearly so—for, after all, he has written "Martin's Puzzle," "The Old Chartist," and "Juggling Jerry." His readers, of the verse even more than of the prose, must be prepared to meet him on a common intellectual footing. But when once that is granted, the music and magic of such poems as "Seed-time," "Hard Weather," "The Thrush in February," "The South-Wester," "The Lark Ascending," "Love in the Valley," "Melampus," "A Faith on Trial," are very real, amid all their occasional obscurities of diction.

Mr Meredith had, however, now completed his sixtieth year, and the angles of his individuality began to grow sharper, while the difficulties of his style, which had never been easy, became accentuated. The increase in mannerism was marked in *One of Our Conquerors* (1891) and in the poem of "The Empty Purse," (1892). Nor did either *Lord Ormont and His Aminta* (1894) or *The Amazing Marriage* (1895) reach the high level of the earlier novels, though in the latter he seemed to catch an afterglow of genius. But by this time Mr Meredith's fame was assured, and the greatness of the work of his prime fully acknowledged. He was chosen to succeed Tennyson as President of the Authors' Society; on his seventieth birthday (1898) he was presented with a congratulatory address by thirty of the most prominent men of letters of the day; and in various other ways his position as the greatest living English writer had come to be popularly recognized. The critics discussed him; and new editions of his books (both prose and verse), for which there had long been but scanty demand, were called for. One of the results was that Mr Meredith, with very doubtful wisdom, recast some of his earlier novels; and in the sumptuous "authorized edition" of 1897 (published by Constable) very large alterations are made in some of them. In fact, a reader who compares the first and last editions either of *Richard Feverel* or *Evan Harrington* will notice changes little short of revolutionary. It is no doubt competent to an author himself to revise his earlier published work even to the extent to which Mr Meredith in the 1897 edition revised these novels; but certainly it is not necessary to accept his judgment when this involves the excision in old age of some of the most virile passages of books that were written in the full glow and vigour of his prime; and one of the duties of future editors will be to restore *Richard Feverel* and *Evan Harrington* to their earliest versions. In 1898 appeared his *Odes in Contribution to the Song of French History*, consisting of one ode ("France, December 1870") reprinted from *Ballads and Poems* (1871), and three others previously unpublished; a fine example of his lofty thought, and magnificent—if often difficult—and individual diction. In 1901 another volume of verse, *A Reading of Life*, appeared.

Mr Meredith's literary quality must always be considered in the light of the Celtic side of his temperament and the peculiarities of his mental equipment. His nature is intuitive rather than ratiocinative; his mental processes are abrupt and far-reaching; and the suppression of connecting associations frequently gives his language, as it gave Browning's, the air of an impenetrably nebulous obscurity. It is this "anfractuosity," to use a word of Dr Johnson's, that leaves much of his poetry, despite the intellect that illumines it and the beauty that lends it colour for readers who will take the trouble to put themselves at the writer's point of view, with a dimness and a blurred outline beyond even the intricacies of his prose. But, when once his manner has been properly understood, it is seen to be inseparable from his method of intellection, and to add to the narrative of description both vividness

of delineation and intensity of realization. The essential respect in which Mr Meredith's method of describing action and emotion in narrative differs from that of convention is that, while the ordinary method is to relate what happens from the point of view of the onlooker, Mr Meredith describes it from the point of emotion of the actor; and his influence in this direction has largely modified the art of fiction. Herein lies the secret of the peculiar brilliancy of his style, derived from his combination of the narrator with the creator, or—in its strict sense—the seer. The reader, by the transference of the interest from the audience to the stage, is transported into the very soul of the character, and made to feel as he feels and act as he acts. Moreover, Mr Meredith's instinct for psychology is so intimate, and his sense of motive and action so true, that the interaction of character and character directly dominates the sequence of events depicted in his imaginary world, and discloses the moral idea or criticism of life, instead of the preconceived "moral" being merely illustrated by the plot. In building up the minds, actions, creeds, and tragedies or comedies of his imaginary personalities amid the selected circumstances, and inspiring them with the identical motives and educational influences of life itself, Mr Meredith has spent an elaboration and profundity of thought and an originality and vigour of analysis upon his novels which in explicitness go far beyond what had previously been attempted in fiction, and which give to his works a philosophical value of no ordinary kind. Simplicity can scarcely be expected of his language, for the interplay of ideas is in itself original and complex, and their interpretation is necessarily original and complex too. But when Mr Meredith is at his best, he is only involved with the involution of his subject; the aphorisms that decorate his style are simple when the idea they convey is simple, elaborate only in its elaboration. Pregnant, vividly graphic, capable of infinite shades and gradations, his style is a much finer and subtler instrument than at first appears, and must be judged finally by what it conveys to the mind, and not by its superficial sound upon the conventional ear. It owes something to Jean Paul Richter; something, too, to Carlyle, with whose methods of narrative and indebtedness to the apparatus of German metaphysics it has a good deal in common. To the novelist Richardson, too, a careful reader will find that Meredith, both in manner and matter (notably in *The Egoist* and in *Richard Feverel*), owes a good deal; in "Mrs Grandison" in *Richard Feverel* he recalls "Sir Charles Grandison" by name; and nobody can doubt that Sir Willoughby Patterne, both in idea and often in expression, was modelled on Richardson's creation. But what is most characteristic in Mr Meredith remains individual. Like all the great masters, he has his own tone of voice, his own fashion of expressing an idea. Feeling, perception, reflection, judgment, have equal shares in determining his architectonic relation to a problem or a situation. He rings changes on the changing emotions of humanity, but every chime rings true. It is beyond our scope here to enter into details concerning the philosophy which represents Mr Meredith's "criticism of life." Broadly speaking, it is a belief in the rightness and wholeness of Nature, when Nature—"Sacred Reality"—is lovingly and faithfully and trustfully sought and known by the pure use of reason. Man must be "obedient to Nature, not her slave." Mystical as this philosophy occasionally becomes, it is in the main inspiring, clean, austere, and practical; and it is always dominated by the categorical imperative of self-knowledge and the striving after honesty of purpose and thought. A strong vein of political Radicalism runs through Mr Meredith's philosophy. It is, however, a Radicalism allied to that

of the French sages rather than to the current developments of British party politics. Mr Meredith has always been strongly French in his sympathies, and his appreciation of French character at its best and at its worst is finely shown in his Napoleon odes. In the main his politics may be summed up as a striving after liberty for reason and conscience and the constant progress of humanity —

The cry of the conscience of life;
Keep the young generations in hail,
And bequeath them no tumbled house.

It is part of Mr Meredith's creed—and this must be remembered in considering his diction—that verbal expression is itself a test of right thought and action. Hence is derived his passion for verbal analysis. Hence also his impulse towards and vindication of poetry—meaning still "the best words in the best order"; and hence his own dictum, otherwise perhaps hard to undiscerning minds, that Song itself is the test by which truth may be tried. The passage occurs in "The Empty Purse"—itself a careful though mannered exposition of Mr Meredith's general views on life:—

Ask of thyself: This furious Yea
Of a speech I thump to repeat,
In the case I would have prevail,
For seed of a nourishing wheat,
Is it accepted of Song?
Does it sound to the mind through the ear,
Right sober, pure sane? has it disciplined feet?
Thou wilt find it a test severe;
Unerring whatever the theme.
Rings it for Reason a melody clear,
We have bidden old Chaos retreat,
We have called on Creation to hear;
All forces that make us are one full stream.

Undoubtedly, as a poet, Meredith is generally ranked far less high than as a novelist. But he can only be understood and appreciated properly by those who realize that not prose (in the ordinary sense) but poetry is to him the highest form of expression, and that only in it can he fully deliver his message as a writer who aspires to contribute something more to the common stock of ideas than can be embodied dramatically in prose fiction.

A carefully compiled bibliography by John Lane is included in *George Meredith: Some Characteristics*. By R. LE GALLIENNE, 1890. (Lane.) (H. CH.; A. WA.)

Mergui, the southernmost district of Lower Burma, in the Tenasserim division, bounded on the W. by the Bay of Bengal and on the E. by Siam. It had in 1876 a population of 51,846, 73,748 in 1891, and 88,667 in 1901, showing an increase of 20·23 per cent. and giving a density of 9 inhabitants to the square mile. The area is 9789 square miles, and it had in 1898-99, 360 villages paying a revenue of Rs.2,98,671. Of the population in 1891, 63,296 were Buddhist and Jains, 5288 Mahommedans, 857 Hindus, 1891 aborigines, mostly Selungs, and 2416 Christians, 2191 of whom were natives. Of the total area of 6,264,960 acres, only 81,785 acres were cultivated in 1898-99; 3,503,259 were not available for cultivation, and 2,482,299 acres apart from fallow were cultivable. The rainfall in 1898-99 taken at Mergui was 150·71 inches. MERGUI town had in 1891 a population of 10,137. There is a considerable coasting trade with other Burmese ports and with the Straits Settlements, but the town does not greatly increase in size. The coal on the Tenasserim river still remains unworked, but a renewed effort is being made to work the Maliwun tin mines by European methods. There were 192,000 acres of forests in the Mergui district in 1889-90.

Merida, a town of Spain, in the province of Badajoz, 30 miles east of Badajoz by rail. The population was

10,886 in 1897. There is an active trade in the agricultural products of the surrounding districts, and such local industries as manufactures of leather, linen goods, soap, and hats have developed. Several improvements have, fortunately, not greatly interfered so far with the priceless treasures of Roman and mediæval antiquities.

Meriden, a city and town of New Haven county, Connecticut, U.S.A., on the New York, New Haven, and Hartford railroad, south-west of the centre of the state, at an altitude of 133 feet. The plan of the city, which is included within the town, is irregular; it is divided into five wards, and the waterworks, which supply water by gravity, are owned by the city. In 1900 its manufacturing establishments had a capital of \$16,699,004, employed an average number of 7531 wage-earners, and had a product valued at \$13,485,640. Of this, plated and Britannia ware had a value of \$4,129,896; hardware, \$1,619,149; and cutlery and edge tools, \$408,493. Population of the town (1890), 25,423; (1900), 28,695; of the city (1890), 21,652; (1900), 24,296, of whom 7215 were foreign born and 207 were negroes. The death-rate of the city in 1900 was 14.3.

Meridian, a city of Mississippi, U.S.A., capital of Lauderdale county, on the Mobile and Ohio, the Queen ant Crescent and the Southern railways, in the eastern part of the state, at an altitude of 344 feet. It is in a region in great part devoted to the production of cotton, of which staple Meridian is a collecting and shipping point of much importance. It is the seat of Eastern Mississippi Female College, a Methodist Episcopal institution, founded in 1869. In 1899 it had 28 instructors and 307 students. Population (1890), 10,624; (1900), 14,050, of whom 235 were foreign-born and 5787 were negroes.

Merioneth, a maritime county of North Wales, is bounded on the N. by Carnarvon and Denbigh, on the E. by Denbigh, on the S.E. by Montgomery, on the S. by Cardigan, and on the W. by Cardigan Bay.

Area and Population.—The area of the ancient county, as given in the census returns of 1901, was 427,910 acres, or 668 square miles, with a population in 1881 of 61,967, in 1891 of 49,212, and in 1901 of 49,130, the number of persons per square mile being 73, and of acres to a person 8.7. In 1895 the area of the administrative county was diminished by the transference of the part of the parish of Beddgelert in Merioneth to Carnarvon. In 1891 its population was 48,859, and in 1901, 48,774. The area of the registration county is 525,802 acres, with a population in 1891 of 64,726. Between 1881 and 1891 the population decreased 5.15 per cent., and between 1891 and 1901, 0.2 per cent. The excess of births over deaths between 1881 and 1891 was 7092, but there was a decrease in the resident population of 3511. The following table gives the numbers of marriages, births, and deaths, with the number and percentage of illegitimate births, for 1880, 1890, and 1898 :—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Number.	Per Cent.
1880	407	2161	1423	137	6.4
1890	365	1723	1213	131	7.6
1898	506	1842	1188	139	7.5

In 1891 there were in the county 102 natives of Scotland, 85 natives of Ireland, and 65 foreigners, while 3621 persons could speak English, 45,856 Welsh, and 12,023 English and Welsh.

Constitution and Government.—The county returns one member to Parliament. It has neither parliamentary nor municipal borough, but the following are urban districts: Bala (1544), Barmouth (2213), Dolgellay (2437), Festiniog (11,435), Mallwyd (890), and Towyn (3744). The county is in the North Wales circuit, and assizes are held at Dolgellay. It is partly in the diocese of Bangor and partly in that of St Asaph, and contains 37 ecclesiastical parishes and districts, and parts of 4 others.

Education.—The total number of elementary schools on 31st August 1899 was 77, of which 50 were board and 27 voluntary schools, the latter including 26 National Church of England schools

and 1 "British and other." The average attendance at board schools was 5808, and at voluntary schools 1580. The total school board receipts for the year ended 29th September 1899 were over £24,212. The income under the Agricultural Rates Act was over £1234.

Agriculture.—Rather more than a third of the total area is under cultivation, and of this more than two-thirds is in permanent pasture, while corn crops occupy an eleventh and green crops less than a fortieth. Oats are the principal corn crop, occupying more than three-fifths of that acreage, while the small acreage under green crops is usually nearly equally divided between potatoes and turnips. There is a specially large proportion of cows among the cattle kept. The following table gives the main divisions of the cultivated area at intervals from 1880 :—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	152,623	16,868	4033	15,067	116,221	434
1885	157,098	17,004	3954	11,225	124,879	36
1890	161,315	16,317	4072	12,160	128,616	150
1895	154,038	14,937	3768	13,897	121,341	95
1900	152,929	13,963	3611	18,698	116,559	98

The following table gives particulars regarding the principal live stock for the same years :—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	6137	38,493	14,827	413,473	8,468
1885	5453	39,500	14,937	399,743	9,059
1890	4998	38,281	14,549	412,878	10,049
1895	5266	38,002	13,998	376,853	9,561
1900	5219	39,518	14,276	433,727	8,137

Industries and Trade.—Manufactures are insignificant, only about 800 persons being employed in factories and workshops. The total number of persons employed in connexion with mines and quarries in 1898 was 6062; 35 tons of gold ore valued at £7 were mined in 1885, 13,264 tons valued at £16,584 in 1895, 708½ tons valued at £1158 in 1898; 155,634 tons of slate valued at £435,438 were dug in 1885, 135,457 tons valued at £456,865 in 1895, and 151,279 tons valued at over £500,000 in 1899. In 1899 sandstone was raised to the amount of 21,856 tons, igneous rocks of 12,808 tons, and slate of 160,565 tons. Fisheries are unimportant.

Merivale, Charles (1808–1893), English historian and dean of Ely, born 8th March 1808, was the second son of John Herman Merivale, a Chancery barrister, and Louisa Heath Drury, daughter of Dr Drury, headmaster of Harrow. Another son was Herman Merivale, formerly permanent Under-Secretary of State for the Colonies (1848), and India (1860). Charles Merivale was at Harrow School (1818 to 1824) under Dr Butler. His chief friends were Charles Wordsworth, afterwards bishop of St Andrews, and Richard Chenevix Trench, afterwards archbishop of Dublin. In 1824 he was offered a writership in the Indian Civil Service, and went for a short time to Haileybury College, where he was distinguished for proficiency in Oriental languages. But he eventually decided against an Indian career, and went up to St John's College, Cambridge, in 1826. Among other distinctions he came out as fourth classic in 1830, and in 1833 was elected fellow of St John's. He was a member of the Apostles' Club, his fellow-members including Tennyson, A. H. Hallam, Monckton Milnes, W. H. Thompson, Trench, and Spedding. He was fond of athletic exercises, had played for Harrow against Eton in 1824, and in 1829 rowed in the first inter-University boat-race, when Oxford won. In 1833 he was ordained, and undertook college and university work successfully, acquiring some fame as a preacher. In 1848 he took the college living of Lawford, near Manningtree, in Essex; he married, in 1850, Judith Mary Sophia, youngest daughter

of George Frere. In 1863 he was appointed chaplain to the Speaker of the House of Commons, declined the professorship of modern history at Cambridge in 1869, but in the same year accepted from Mr Gladstone the deanery of Ely, and until his death on 27th December 1893 devoted himself to the best interests of the cathedral. He received many honorary academical distinctions. His principal work was *A History of the Romans under the Empire*, in seven volumes, which came out between 1850 and 1862; but he wrote several smaller historical works, chiefly of an educational character, and published sermons, lectures, and Latin verses. His history did much to popularize the study of Roman history during the Empire, and was the first readable book on the subject that covered the ground satisfactorily. Merivale as a historian cannot be compared with Gibbon for virility, but he takes an eminently common-sense and appreciative view. The chief defect of the book, inevitable at the time it was composed, is that, drawing the materials from contemporary memoirs rather than from inscriptions, he relies on literary gossip rather than on the evidence of fact that inscriptions alone can supply. His judgment of character is mainly ethical, and not sufficiently relative to circumstances. The style is easy and flowing, but has a rotundity now unfashionable, and adapted to gliding skilfully over difficulties imperfectly apprehended. The Dean was an elegant scholar, and his rendering of the *Hyperion* of Keats into Latin verse (1862) has received high praise. A typical instance of the *mens sana in corpore sano*, his geniality was seasoned by an acute, almost caustic sense of humour, and it may be questioned whether he would have been more severe to fanaticism or listlessness. He had none of the faults or affectations of the pedant, and was eminently a practical man, with an accurate memory and a good head for business. His vigorous enjoyment of life, his shrewd interest in men and affairs, continued unabated to the last.

(A. C. BE.)

Merrill, a city of Wisconsin, U.S.A., capital of Lincoln county, on the Wisconsin river and the Chicago, Milwaukee, and St Paul railway, north of the centre of the state, at an altitude of 1263 feet. In 1900 the city contained 69 manufacturing establishments, with a total capital of \$3,520,126, products valued at \$4,150,272, and 1694 wage-earners. It is in a heavily-timbered region, and its manufactures consist in great part of lumber. Population (1890), 6809; (1900), 8537, of whom 2399 were foreign-born.

Merrimac River, a stream of New Hampshire and Massachusetts, U.S.A., rising in the White Mountains of New Hampshire and flowing south into Massachusetts, and thence north-east to its mouth at Newburyport. Its length is 110 miles, and it drains an area of 4864 square miles. Its course is through a glaciated region, in consequence of which it is interrupted by many rapids and falls, which have been extensively utilized as sources of water power in the manufacture of cotton and woollen goods, notably at Lawrence and Lowell, Massachusetts, and at Nashua and Manchester, New Hampshire. This stream probably drives more spindles than any other river in the world.

Merritt, Wesley (1836—), American soldier, was born in New York City on the 16th of June 1836, and after graduating at West Point in 1860, was assigned to dragoon service. During the Civil War he gained renown as a cavalry officer, serving in successive Virginia campaigns, under Stoneman and Sheridan. He was made a major-general of volunteers on 1st April 1865, and was promoted gradually from lieutenant-colonel of regulars to major-general. He served in Indian cam-

paigns, as superintendent at West Point, and in command of military departments. He was assigned in May 1898 to the command of the United States forces that were sent to the Philippines, after Admiral Dewey's victory, and made first military governor of the islands. He was retired from service, June 1900.

Merscheid, a town of Prussia, in the Rhine province, now known as OHLIGS.

Merseburg, a town of Prussia, province of Saxony, on the left bank of the Saale, 9 miles by rail south of Halle. The cathedral was thoroughly restored in 1883-86. A new meeting-hall of the provincial estates was built in 1895. The castle, built in 1483-1561, but restored in the 17th century, now serves Government purposes. A bronze statue of the Emperor Frederick III. (1894), and another of the Emperor William I. (1897), adorn the town. Population (1885), 16,828; (1900), 19,119.

Mersina, a town of recent foundation, on the south coast of Asia Minor, in the vilâyet of Adana, and the port (an open roadstead) of Tarsus and Adana, with which it is connected by railway and road. The population of 12,500 is half Moslem, half Christian. The average annual exports in 1896-1900 were valued at £639,830 (1900, £821,243), the imports at £332,639 (1900, £269,121). The town is the seat of British and other consuls.

Merthyr Tydfil, a parliamentary borough and market town of Glamorganshire, Wales, on the river Taff, 24 miles by the Taff Vale railway north-north-west of Cardiff, with which it is also connected by canal. The iron ore here treated is mainly imported from Spain. At Merthyr Vale is one of the largest collieries in South Wales. A theatre has been erected, seating 1800 persons and lighted by electricity. A Roman Catholic church (1894) and a town hall (1898) have been erected; and the General Hospital, built in 1887, was enlarged in 1897. Population (1891), 59,004; (1901), 69,227.

Merv, formerly a large and flourishing town in the east of the oasis of the same name, in western Asia, now in ruins. NEW MERV was founded in the first quarter of the 19th century, more to the west of the oasis, and is now a district town of Russia, in the Transcaspian province, and on the Transcaspian railway, 510 miles from Uzun-ada station on the Caspian Sea, and 381 miles from Samarkand. It stands on both banks of the Murghab, at an altitude of about 820 feet above the Caspian, the Russian fort being situated on the right bank of the river. It is a well-built town, with (1897) 8729 inhabitants, Russians, Armenians, Turkomans, Persians, and Jews. It has a Greek and an Armenian church, and a synagogue, a Russian and two Mussulman schools, a hospital, and a meteorological observatory. Its trade returns are considerable. Corn, raw cotton (two factories), hides, wool, nuts, and dried fruit are exported. The climate is extremely dry and continental; there is often no rain from June till October, and the total rainfall is but 5 inches; the average yearly temperature is 60° Fahr. The Merv oasis was taken possession of by Russia in 1884.

Meshed, properly MASH-HAD (the place of martyrdom), capital of the great Persian province of Khorassan, situated in 36° 17' N. and 59° 36' E., at an elevation of 3180 feet. Its population is about 70,000 fixed and 10,000 floating, the latter consisting of pilgrims to the shrine of Imam Riza. Without the pilgrims, who come to visit it to the number of over 100,000 yearly, Meshed would be but a poor place; but lying on the eastern confines of Persia, close to Afghanistan, Russian Central Asia, and Transcaspia, at

the point where a number of trade routes converge, it is very important politically, and the Russian and British Governments have maintained consulates-general there since 1889. Meshed had formerly a great transit trade to Central Asia: of European manufactures, mostly Manchester goods, which came by way of Trebizond, Tabriz, and Tehran; and of Indian goods and produce, mostly muslins, Indian and green teas, which came by way of Bander Abbasi. With the opening of the Russian railway from the Caspian to Merv, Bokhara, and Samarkand in the 'eighties, Russian manufacturers were enabled to compete in Central Asia with their western rivals, and the value of European manufactures passing Meshed in transit was much reduced. In 1894 the Russian custom-house enforced new regulations by which a heavy duty is levied on Anglo-Indian manufactures and produce, excepting pepper, ginger, and drugs, imported into Russian Asia by way of Persia; and the importation of green teas is altogether prohibited except by way of Batum, Baku, Uzun-ada, and the Transcaspien railway. Since then the transit trade is practically *nil*. The present trade of Meshed is estimated at: exports, £120,000; imports, £210,000. In 1890 General Maclean, the British consul-general, reported that there were 650 silk, 40 carpet, and 320 shawl looms at work; in 1898 Colonel Temple mentioned 250 silk and 200 carpet looms. The Imperial Bank of Persia opened a branch at Meshed in 1891. (A. H.-S.)

Mesopotamia.—Since 1885 the Porte has been gradually extending its authority over the nomads in Mesopotamia. When Sheikh Fâris, the paramount sheikh of the northern Shammar Arabs, made his submission he was appointed Pasha, and maintained order within the limits of his authority. Some of the smaller tribes, on the outskirts of the desert, have been settled in villages; in several localities the Sultan owns large private estates, upon which there are model farms; small military posts have been established to protect the agricultural colonies from Arab raids; and in 1892 a special school was opened at Constantinople for the sons of influential Kûrd and Arab sheikhs. There has been a great extension of cultivation in the Euphrates valley: the rich lands south of Jebel Sinjar are cultivated, and villages have been built on them; Rakka has been occupied by colonists from Aleppo; and the Circassians of Râs el-Ain have planted colonies as far south as Jebel Abdul-aziz. In 1892 the most influential chiefs of the Yezidis were treacherously murdered at Mosul by Omar Pasha, and an attempt was made to exterminate the sect. This was checked by an appeal to Constantinople through the European consuls at Mosul. Throughout the country there has been a great increase of German influence, especially since the extension of the Anatolian railway to Diarbekr, Mosul, and Baghdad was projected.

Messina, a city of Italy in the north-east corner of the island of Sicily, with an excellent harbour opening upon the strait of the same name. Owing to its excellent position, Messina has gradually recovered its importance, and now, with a population of 156,552, is the second city of Sicily. Its harbour, strongly fortified, is visited by most of the vessels which pass through the Mediterranean to the Suez Canal eastward bound. In consequence it has become an important trade centre with a large number of wealthy commercial houses. Some industries have been established and show signs of flourishing. Agricul-

ture, however, is the principal occupation of the district, although the province of Messina is one of the poorest of the island. Excellent silk is produced, Messina being in this respect ahead of the rest of Sicily. Except the cathedral, begun by the Normans and enlarged and embellished by Angevins and by the Spaniards, Messina has few ancient monuments, earthquakes having time after time ruined the most important edifices. By the Casati Law on higher instruction in Italy, the University of Messina was in 1860 given second-class status and its faculties restricted to law and medicine. It underwent a period of decadence from 1860 to 1885. In the latter year a Consorzio Universitario, in which the municipality, the provincial authorities, and the Chamber of Commerce were represented, provided funds for the extension of the University, and obtained from Parliament a law conferring upon it first-class status, with the addition of faculties of philosophy and letters, and of natural science and mathematics. In 1899 the University possessed 41 official and 31 free chairs. Its students, who in 1890 numbered only 302, had in 1900 increased to 672, a development due chiefly to the reputation of the various professors. In 1896, 6370 vessels of 3,257,403 tons entered and cleared the port, unloading and loading 379,623 tons of goods; in 1898, 7478 vessels of 3,392,756 tons, unloading and loading 391,201 tons of goods, entered and cleared.

Metallography.—The examination of metals and alloys by the aid of the microscope has assumed much importance in comparatively recent years, and it might at first be considered to be a natural development of the use of the microscope in determining the constitution of rocks, a study to which the name petrography has been given. It would appear, however, that it is an extension of the study of the structure of meteoric irons. There can be no question that in the main it was originated by Dr Sorby, who in 1864 gave the British Association an account of his work. His later papers will be referred to in the bibliography. Following the work of Sorby came that of Professor Martens of Charlottenburg, presenting many features of originality. Although much of his work dealt with the examination of opaque bodies and the application of the method to the various products of the metallurgy of iron, he studied also the general laws of fractures, fissures, blow-holes, and crystallization in metals. M. Osmond, who was one of the earliest to recognize the importance of micrography, has made certain branches of the work peculiarly his own, and has obtained results in connexion with iron and steel which are of the highest interest. A list of the more important papers by these and other workers will be found in the appended bibliography.

Preparation of the Specimen.—Experience alone can enable the operator to determine what portion of a mass of metal or alloy will afford a trustworthy sample of the whole. In studying a series of binary alloys it has been found advantageous in certain cases to obtain one section which will show in a general way the variation in structure from one end of the series to the other. This has been effected by pouring the lighter constituent carefully on the surface of the heavier constituent, and allowing solidification to take place. A section through the culot so obtained will show a gradation in structure from pure metal on one side to pure metal on the other. A thin slice of metal is usually cut by means of a hack-saw, and for this purpose saws driven by mechanism are frequently used. The thickness of the piece should not be less than $\frac{1}{4}$ inch, and

in order that it may be firmly held between the fingers it should not be less than 1 inch square. The preliminary stages of polishing are effected by emery paper placed on plate glass, or preferably on wooden discs capable of being revolved at a high rate of speed. The finest grade of emery paper that can be obtained is used towards the end of the operation. Before use the finer papers should be rubbed with a hard steel surface to remove any coarse particles. The completion of the operation of polishing is effected in various ways, according to the nature of the specimen. It is generally effected on wet cloth or parchment covered with a small amount of carefully washed jeweller's rouge. Various mechanical appliances are employed to minimize the labour and time required for the polishing. These usually consist of a series of interchangeable revolving discs, each of which is covered with emery paper, cloth, or parchment, according to the particular stage of polishing for which it is required. In the case of brittle alloys and of alloys having a very soft constituent, which during polishing tends to spread over and obliterate the harder constituents, polishing is in many cases altogether avoided by casting the alloy on the surface of glass or mica. In this way, with a little care, a perfect surface is obtained, and it is only necessary to develop the structure by suitable etching. In adopting this method, however, instances have occurred in which

the removal of the cast surface has shown a structure differing considerably from the original.

Polishing in Bas-Relief.—If the polishing be completed with fine rouge on a sheet of wet parchment, placed upon a comparatively soft base such as a piece of deal, certain soft constituents of an alloy may often be eroded in such a manner as to leave the hardest portions in relief. For the later stages of polishing Le Chatelier recommends the use of alumina obtained by the calcination of ammonium alum; and for the final polish of soft metals, chromium oxide.

Development of the Structure by Reagents.—Usually the constituents of an alloy do not possess a characteristic or distinctive tint, and polishing is supplemented by reagents which serve to reveal the constituents by the varying degree to which they are acted upon. Osmond divides these into three classes—acids, halogens, and salts. As regards acids, water containing from 2 to 10 per cent. of hydrochromic acid is useful. It is made by mixing 10 grams of potassium bichromate with 10 grams of sulphuric acid in 100 grams of water. The use of nitric acid requires much experience. It is frequently employed in the examination of steels, and the writer prefers to use a 1 per cent. solution in alcohol, although many workers use concentrated acid, and effect the etching by allowing a stream of water to dilute the film of acid left on the

FIG. 1.—Micrographic Apparatus.

surface of the specimen after dipping it. Of the halogens, iodine is the most useful. A solution in alcohol is applied, so that a single drop covers half a square inch of surface. The specimen is then washed with alcohol, and dried with a piece of fine linen or chamois leather. Tincture of iodine also affords a means of identifying lead in certain alloys by the formation of a yellow iodide of lead, while the vapour of iodine has in certain cases been used to tint the constituents. Thin coloured films may often be produced by the oxidation of the specimen when heated in air. This, as a means of developing the structure, in the case of the copper alloys is specially useful. Tinted crystals may thus be distinguished from the investing layer caused by the presence of a minute quantity of another constituent. The temper colours produced by heating iron or steel in air are well known. Carbide of iron is less oxidizable than the iron with which it is intimately associated, and it assumes a brown tint, while the iron has reached the blue stage. These coloured films may be fixed by covering with thin films of gelatine.

In some cases the alloy may be attacked electrolytically by exposing it for a few minutes to a weak electric current in a bath of very dilute sulphuric acid. Certain organic bodies give very satisfactory results. The Japanese, for instance, produce very remarkable effects by simple reagents of which an infusion of certain forms of grass is a not unimportant constituent. In the case of iron and steel a freshly-prepared infusion of liquorice root has been found to be most useful for colouring certain constituents of steel. M. Osmond, who was the first to use this reagent, insisted that it should be freshly prepared and always used

under identical conditions as regards age and concentration. His method of applying it was to rub the specimen on parchment moistened with it, but he has subsequently modified this "polish attack" by substituting a 2 per cent. solution of ammonium nitrate for the liquorice infusion. In each case a small quantity of freshly-precipitated calcium sulphate is used on the parchment to assist the polishing.

Appliances used in Micrography.—The method of using the microscope in connexion with a camera for photographic purposes will now be considered. Every micrographer has his own views as to the form of an installation to be adopted, and it will therefore be well to give an illustration of a definite apparatus (Fig. 1) which has been found to give satisfactory results. It consists of a microscope A with a firm base placed in a horizontal position. The microscope can be connected by a tube B with the expanded camera CC, at the end of which is the usual frame to receive the photographic plate. A practised observer can focus on a plate of clear glass by the aid of a subsidiary low-power microscope lens. If a semi-transparent plate is employed it should be as fine as possible. The surface of the table is cut in such a way near H that the observer who is seated may conveniently examine the object on the stage of the microscope, the portion B turning aside for this purpose. The subsequent focussing is effected by a rod, FFF, and gearing attached to the fine adjustment of the microscope, GA; flap J when raised forms the support of the lamp used for illumination. As an illuminant an arc light has many advantages, as the exposure of the plate used will seldom exceed 10 seconds. An incandescent lamp or a gas

lamp with a mantle will give good results, but with much longer exposure. Actual illumination is best effected by a Beck vertical illuminator or a Zeiss prism. It is necessary that the lens used for concentrating the light on the illuminator should be an achromatic one, as colour effects cause trouble in photographing the objects. For lower powers the Lieberkuhn parabolic illuminator is useful. Certain groups of alloys show better under oblique illumination, which may be effected by the aid of a good condensing lens, the angle of incidence being limited by the distance of the object from the objective in the case of high magnification. As regards objectives, the most useful are the Zeiss 2 mm., 4 mm., and 24 mm.; two other useful objectives for low powers being 35 mm. and 70 mm., both of which are projecting objectives. A projecting eye-piece, preferably of low power, should be employed with all but the two latter objectives. The immersion lens, the Zeiss 2 mm., is used with specially thickened cedar oil, and if the distance from the objective to the plate is 7 feet, magnifications of over 2000 diameters can easily be obtained (see Plate). As regards sensitized plates, excellent results have been obtained with Lumière plates sensitive to yellow and green. The various brands of "process" plates are very serviceable where the contrasts on the specimen are not great.

Metal Work, Art.—The term "art metal work" is applied to those works in metal in which beauty of form or decorative effect is the first consideration, irrespective of whether the object is intended for use or is merely ornamental; and it embraces any article from a Birmingham brass bedstead to works of the highest artistic merit. The term, as definitely distinguishing one branch of metal-working from another, has scarcely been in use for more than half a century, and is objected to by many on the ground that no such prefix was required in the best periods of art, and that allied crafts continue to do without it to the present day. Indeed, as long as metal-working remained a handicraft—in other words, until the introduction of steam machinery—every article, however humble its purpose, seems to have been endowed with some traditional beauty of form. The ceaseless changes in taste and fashion attendant upon progressive civilization, the proclivities of rulers, foreign alliances, facilities for travel, and the opening up of new areas to trade, had led to the evolution of a long series of distinct

styles, developed without apparent effort by successive generations of craftsmen. The robust, florid, and distinctly Roman rendering of the classic, which followed the refined and attenuated treatment associated with the architecture of the brothers Adam, who died in 1792 and 1794, is the last development in England which can be regarded as a national style. The massively moulded ormlu stair balustrade of Northumberland House, now at 49 Prince's Gate; the candelabra at Windsor and Buckingham Palaces, produced in Birmingham by the firm of Messenger; the cast-iron railings with javelin heads and lictors' fasces, the tripods, Corinthian column. standard lamps and candelabra, boat-shaped oil lamps and tent-shaped lustres with classic mountings, are examples of the metal work of a style which, outside the eccentric Brighton Pavilion and excursions into Gothic and Elizabethan, was universally accepted in the United Kingdom from the days of the Regency until after the accession of Victoria. Except perhaps the silversmiths, no one was conscious of being engaged in "art metal-working," yet the average is neither vulgar nor in bad taste, and the larger works are both dignified and suited to their architectural surroundings.

The introduction of gas as an illuminant, about 1816, at once induced a large demand and a novel description of metal fitting; and with this the craft fell under the control of a new commercial class, imbued with expansive notions of free trade, eager to supply the markets of the world, intent on breaking with past traditions, and utilizing steam power, electro-deposition, and every mechanical and scientific invention tending to economize metal or labour. Such were the conditions of metal-working, especially as carried on in the great centres of Birmingham and Sheffield, at this time. But when all artistic perception in Great Britain appeared lost in general admiration of the triumphs of machinery and the expansion of trade, a new influence in art matters, that of the Prince Consort, began to make itself felt. The Great Exhibition, state-aided schools of design, the South Kensington Museum, and the establishment of a Science and Art Department under Government, are among the results of the important art revival which he inaugurated. He is credited with having himself designed candelabra and other objects in metal, and he directly encouraged the production of the sumptuous treatise on metal work by Digby Wyatt, which laid the foundations of the revival. To this work, and that of Owen Jones, can be traced the origin of the eclecticism which has laid all past styles of art under contribution. The Gothic revival, pursued simultaneously but quite independently, also helped in a general way the recognition of art, without very directly affecting the movement. It did, however, lead to a profound study of one of the bygone phases of the art of Great Britain, and was especially valuable in teaching how to work within definite limitations, but without slavish copying; it also emancipated a considerable body of craftsmen from the tyranny of manufacturers whose sole idea was that machine work should supercede handicraft. Its greatest efforts were the metal chancel screens designed by Sir G. G. Scott, that for Hereford Cathedral having been exhibited in 1862. The effect produced by these, though purporting to be strictly Early English in character, could hardly on the whole have been conceived by the designers and workers of that period. It does not appear that the influence either of Owen Jones or Digby Wyatt on metal-working extended beyond bringing the variety and beauty of past styles to the direct notice of designers. They did not actually themselves produce designs affecting the development of the metal crafts. Neither can the London silversmiths, though they employed the best talent available, particularly

in the decade following the Great Exhibition of 1851, be credited with directing or even much influencing the art metal revival, especially of later years. They were rivalled by Elkington of Birmingham, who secured the permanent assistance of at least one fine artist, Morel Ladeuil, the producer of the Elcho Challenge Shield. Perhaps the first actual designer to make a lasting impression on the crafts was Thomas Jeckyll, some of whose work, including gates for Sandringham, was exhibited in 1862. Infinitely greater as a designer was Alfred Stevens, whose influence on English craftsmen might be regarded as almost comparable to that of Michelangelo on that of his Italian contemporaries. Stevens's designs certainly directly raised the standard of production in several metal-working firms by whom he was employed; whilst in the Wellington Memorial in St Paul's Cathedral, and in Dorchester House, his work is seen unfettered by commercial considerations. Omitting many whose occasional designs have had little influence on the development of the metal crafts, we come to Alfred Gilbert, whose influence for a time has been scarcely less than that of Stevens himself. Monumental works, like his statue of Queen Victoria at Winchester and his work at Windsor, may be handed down as his greatest achievements, but judged as art metal work, his smaller productions, such as the centre-piece presented by the army and navy to Queen Victoria on her Jubilee, have been more important.

The charming bronze statuettes of Onslow Ford, the most representative of which are in the Tate Gallery; the work of George Frampton, as seen in the Mitchell Memorial; and the beautiful bas-reliefs of W. Stirling Lee, examples of which are illustrated in the bronze gates of the Adelphi Bank at Liverpool (see Plate), have all contributed, especially when applied to architectural decoration, to a high standard of excellence. Painters also have frequently designed and modelled for metal work, like Lord Leighton, who produced bronze statuettes of most refined character; and Sir L. Alma-Tadema, who designed the grilles for his studio and entrance hall; but none have devoted themselves so conspicuously to it as Professor von Herkomer, who, whether working in gold and enamel, iron, or his favourite alloy, pewter, infuses a freshness into his designs and novelty into his methods which display an unusual mastery over materials.

The gift of reproducing effects of nature or art by brush or chisel is not, however, accompanied necessarily by power to design, as many have discovered; but a noteworthy exponent of the dual faculty is G. C. Haité, whose designs are widely applied.

It is chiefly to architecture that metal work owes its permanent, steady, and comprehensive artistic improvement. Good architecture creates good craftsmen, and together they have ever stood and fallen. The buildings of Norman Shaw and Ernest George demanded quiet and harmonious metal work; and the custom of these architects of superintending and designing every detail, even for interiors, created the supply. Such men educate those they employ, and apt pupils gather round them. The work of every worthy architect raises the standard of the crafts; but beyond others Messrs Ashbee, Lethaby, and Wilson have taken an active personal interest in schools of metal work. The technical schools, maintained or subsidized by corporate bodies, have also been of immense service in creating a class of intelligent, capable, and self-respecting craftsmen, whose wages, proportioned to their skill, enable them to regard their work not merely as irksome toil, but as worthy occupation abounding in interest. Home industries, carried on far from the recognized centres, such as the metal work-

ing round Keswick, executed during hours of enforced idleness by field labourers and railway porters, educate the passer-by as well as the worker. This admirable school, founded in 1884 by Canon and Mrs Rawnsley, to provide recreation as well as remunerative work, was in 1901 attended by about fifty men during the winter, in addition to employing a permanent staff of twelve.

Architects and artists who design for the principal decorating firms are to-day as conversant with the Renaissance and succeeding styles of France and Italy as mediæval revivalists were familiar with the Gothic styles with which they made us so well acquainted. Metal work more or less based upon every kind of past style, and appropriate to the most varied architectural and decorative surroundings, is produced in vast quantities, and in some cases so skilful are the workers that modern forgeries and reproductions are almost beyond the power of experts to detect. This large class of designers and craftsmen, to whom a thorough knowledge of the history of design is a necessity, may be distinguished as conventional, following and developing traditional lines. The new art school, on the contrary, breaks wholly with tradition, unless unconsciously influenced by the Japanese, and awards the highest place to originality in design. It is not to be expected that an art revival following on, and in possession of, all the results of a period of unprecedented activity in scientific research should proceed as leisurely or with the same restraint as heretofore; but unfettered activity, and the general encouragement almost ostentatiously to abandon the traditions of art, have no exact parallel in the past, and may yet prove a danger. It is perhaps the very rapidity of the movement, so characteristic of the age, that is likely to retard its progress and to fail to carry with it the wealthy clients and the decorators they employ, or perhaps even to increase the disposition, already apparent, to cling to the safe ground of reproductions of the styles of the 17th and 18th centuries. The multiplication of art periodicals, lectures, books, photographs, meetings of societies and guilds, museums, schools of arts and crafts, polytechnics, scholarships, facilities for travel, exhibitions, even those of the Royal Academy, to which objects of applied art are now admitted, not only encourages many persons to become workers and designers in the applied arts, but exposes everything to the attentions of the plagiarist, who travesties the freshest idea before it has well left the hands of its originator. Thus the inspirations of genius, appropriated by those who imperfectly appreciate their subtle beauty and quality, become hackneyed and lose their charm and interest. The keen desire to be unconventional in applied art has spread from Great Britain and the United States to Germany, Austria, and other countries, and is, in fact, everywhere apparent, but without concerted lines, well-defined first principles, or limitations. Individuals may follow Rossetti, or Burne-Jones, or William Morris, or any other brilliant masters at home or abroad, but neither artists nor public are agreed as to any particular school being best worth development. It seems agreed in a general way that the completed work in metal is to be wholly the conception and, as far as possible, the actual handiwork of the designer: casting by the *cire-perdue* process, left practically untouched from the mould, and embossing, being the two most favoured processes. The female figure is largely made use of in every class of unconventional design, and rich and harmonious colours are sought, the glitter of metal being invariably subdued by deadening its lustre, or by patinas and oxides. Gilding, stains and lacquers, electro-plating, chasing, "matting," frosting, burnishing, mechanically produced mouldings and enrichments, and the other processes esteemed in the 19th century, are disused and avoided. New contrasts are formed by the

juxtaposition of differently toned metals; or these with an inlay of haliotis shell, introduced by Alfred Gilbert; or of coloured wax, favoured by Onslow Ford; or enamelling, perfected by Professor von Herkomer; or stained ivory, pearls, or semi-precious stones. The quality of the surface left by the skilled artist or artisan is more regarded than symmetry of design, or even than correct modelling. Frequently only the important parts in a design are carefully finished and the rest merely sketched, the mode of working, whether by modelling tools or hammer, being always left apparent.

The newer kinds of art metal work have, until recently, reached the purchaser direct from the producer's workshop, but they may now also be seen in the shops of silversmiths, jewellers, and general dealers, who are thus helping to transfer production from large commercial manufactories to smaller ateliers under artistic control. The production of the larger household accessories, such as bedsteads, fenders, gas and electric fittings, clocks, &c., has hardly as yet come under the influence of the art movement. The services rendered by Mr W. A. S. Benson of Chiswick, who by his practical and elegant designs commenced about 1886 to revolutionize the production of sheet-brass and copper utensils, cannot be passed over in this connexion. The average ecclesiastical metal work has upon the whole rather receded than progressed in merit, except when it is specially designed by architects and executed under their supervision. Though the demand for good domestic wrought-iron work has enormously increased, adaptations from the beautiful work of the 17th and 18th centuries have been found so suited to the architectural surroundings amidst which they are placed, that entirely new departures have hitherto been relatively uncommon. Of such the gates for Sandringham, by Jeekyll; for Crewe Hall, by Charles Barry; and for the Victoria and Albert Museum, by Gamble, are the earliest and best known. Of the vast number designed upon traditional lines may be cited those for Lambton Castle, Welbeck, Eaton Hall, Twickenham, Cliveden, and the Astor Estate Office on the Victoria Embankment. Cast iron, brought to perfection by the Coalbrookdale Company about 1860, but now little esteemed, owing to the poverty of design which so often counterfeits smith's work, presents great opportunities to founders possessing taste or willing to submit to artistic control. A very large field is also opening for cast-lead work, whether associated with architecture, as in the leaden covered-way over Northumberland Street, in London (see Plate), and the fine rain-water heads of the Birmingham Law Courts (see Plate), or with the revival of the use of metal statuary and vases in gardens. The subdued colour and soft contours of pewter render it once more a favoured material, peculiarly adapted to the methods of the art revival, and perhaps destined to supersede electro-plate for household purposes. In silver work the proportion of new art designs exhibited by dealers and others is still relatively small; but jewellers, except when setting pure brilliants and pearls, are becoming more inclined to make their jewels of finely modelled gold and enamel enriched with precious and semi-precious stones, than of gems merely held together by wholly subordinate settings.

On the continent of Europe, France was undoubtedly the first to recognize the merits of its bygone designers and craftsmen, and even antecedent to the Exhibition of 1851, when art in Great Britain was practically dormant, it was possible to obtain in Paris reproductions of the finest ormolu work of the 18th century faithfully rendering the characteristics of the originals. At the same time a most active production of modern designs was proceeding, stimulated by rewards, with the result that the supply of clocks, lamps, candelabra, statuettes, and other ornaments

in bronze and zinc to the rest of Europe became practically a monopoly of Paris for nearly half a century. In all connected with their own homes the French adhere to their traditions far more than other nations, and the attempt at originality in the introduction of metal work into the scheme of decoration of a room is almost unknown. In the domain of bronze and imitation bronze statuary the originality of the French is absolutely unrivalled. And not only in bronze, but in Paris jewellery, enamels, silver, pewter, and iron work an excessively cultured refinement is apparent, beside which other productions, even the most finished, appear imperfectly developed and crude. The French artist attains his ideal, and it is difficult to imagine, from his standpoint, that the metal-work of the present can be surpassed. The best English metal-worker, on the contrary, is probably not often quite satisfied with the results he attains, perhaps because in Great Britain the pursuit of art has for centuries been fitful and individual, while in France art traditions have been continuously developed and maintained, and are hereditary. The British temperament may cause French art to be regarded by many as exotic and over-developed, but the fact remains that their metal-work is approached in power and technique by a very few of the best British artists. The metal-work of Belgium is based at present entirely on that of France, without attaining the same standard, unless designed for ecclesiastical uses. In Holland these crafts have not progressed. Italian metal-workers are now mainly employed in reproduction, but traditions linger, either of the goldsmith or blacksmith, in some remote parts, while the sporadic appearance of craftsmen of a high order is evidence that the ancient artistic spirit is not wholly extinct. Similarly, the surprising damascening by Messrs Zuluaga of Madrid in the monument to General Prim, and that of Alvarez of Toledo, give hope that the Spanish craftsman only needs to be properly directed. German and Austrian workers had for years shown more energy than originality, but they have recently embraced the newest English developments and carried them to extremes of exaggeration. For really fresh and progressive indigenous art we may perhaps have, in the near future, to turn to America and to Russia, where, having little artistic past to refer to, designers and craftsmen display unequalled individuality and force. It is from the Far East, however, that the most serious rivalry may be anticipated. The metal-work of China and Japan, so pleasantly naïve and inexpensive, though becoming undesirably modified as to design through contact with European buyers, is losing none of its matchless technique, which indeed in Japan is still being developed. In any history of the art revival the influence of such firms as Barbedienne and Christoffe in Paris and Tiffany in New York cannot be ignored. The example and success of the latter probably did much to stimulate workers in England. Their aim, however, has been consistently to surpass existing standards in beauty and originality, without departing from recognized canons of art. The "new art" of Great Britain, so earnestly and actively promulgated, has no doubt a fine future, but its immediate expansion is checked and limited by the pronounced partiality of the wealthy classes for antiques and reproductions. On this account, immense sums are still spent in Paris and elsewhere abroad upon metal work destined for British and American houses, while the money available to be spent on works of art flows mainly into the pockets of the dealers in bric-à-brac. This patronage can be intercepted, and a settled preference for modern British art induced, not by ignoring the beauty and magnificently decorative effects of the works that are preferred, but by careful study of the works of the past, with a view to equalling or surpassing them in the qualities which render them so attractive. (J. s. G.)

METAPHYSICS.

§ 1. METAPHYSICS THE SCIENCE OF BEING.

SIDE by side with psychology, the science of mind, and with logic, the science of reasoning, metaphysics is tending gradually to reassert its ancient Aristotelian position as the science of being in general. Not long ago, in England at all events, metaphysics was merged in psychology. But with the decline of dogmatic belief and the spread of religious doubt about the creation and government of the world; as the special sciences also grow more general, and the natural sciences become more speculative about matter and force, evolution and teleology; men begin to wonder again, like the Greeks, about the nature and origin of things, and half unconsciously discover that they are metaphysicians. Nor must we expect any great difference between the old and the new methods of dealing with these problems, when the causes have been similar: the decay of polytheism in Greek religion and his own discoveries in natural science were the motives which impelled Aristotle to metaphysical questions. There is, however, a certain difference in the way of approaching things. Aristotle emphasized being as being, without always sufficiently asking whether the things whose existence he asserted are really knowable. We, on the contrary, mainly through the influence of Descartes, rather ask what are the things we know, and therefore, some more and some less, come to connect ontology with epistemology, the science of being with the science of knowing, and in consequence come to treat metaphysics in relation to psychology and logic, from which epistemology is an offshoot. To this pressing question then—What is the world as we know it?—three kinds of definite answers are returned: those of materialism, idealism, and realism, according to the emphasis laid by metaphysicians on body, or mind, or on both. Metaphysical materialism is the view that everything known is body or matter; but while according to ancient materialists soul is only another body, according to modern materialists mind without soul is only an attribute or function of body. Metaphysical idealism is the view that everything known is mind, or some mental state or other, which some idealists suppose to require a substantial soul, others not; while all agree that body has no different being apart from mind. Metaphysical realism is the intermediate view that everything known is either body or soul, neither of which alone exhausts the universe of being. Aristotle, the founder of metaphysics as a distinct science, was also the founder of metaphysical realism, and still remains its main authority. His view was that all things are substances, in the sense of distinct individuals, each of which has a being of its own different from any other, whereas an attribute has only the being of its substance (*Met.* Z 1-3; *Post. An.* I 4); that bodies in nature are obviously natural substances, and as obviously not the only kind of substance; and that there is supernatural substance, *e.g.*, God, who is an eternal, perfect, living being, thinking, but without matter, and therefore not a body. At the present day realism is despised on the ground that its differentiation of body and soul, natural and supernatural, ignores the unity of being. Indeed, in order to oppose this unity of being to the realistic duality, both materialists and idealists nowadays arrogate to themselves the title of monists, and call realists dualists by way of disparagement. But we cannot classify metaphysics by the antithesis of monism and dualism without making confusion worse confounded. Not to mention that it has led to

another variety, calling itself pluralism, it confuses materialism and idealism. Extremes meet; and those who believe only in body, and those who believe only in mind, have an equal right to the equivocal term "monist." Moreover, there is no real opposition between monism and dualism, for there can very well be one kind of being, without being all body or all soul; and as a matter of fact, Aristotelian realism is both a monism of substance and a dualism of body and soul. It is in any case unfair to decide questions by disparaging terms, and to argue as if the whole choice were between materialistic or idealistic monism, leaving realism out of court. In this case it would also hide the truth of things, which requires two different kinds of substance, body and soul. The strength of materialism consists in recognizing nature without explaining it away, its weakness in its utter inability to explain consciousness either in its nature or in its origin. On the other hand, it is the virtue of idealism to emphasize the fact of consciousness, but its vice to exaggerate it, with the consequence of resorting to every kind of paradox to deny the obvious and get rid of bodies. There are in reality two species of substances, or entirely distinct things, those which are impenetrably resisting, and those which are conscious substances; and it is impossible to reduce bodies and souls to one another, because resistance is incompatible with the attributes of spirit, and consciousness inexplicable by the attributes of body. So far true metaphysics is a dualism of body and soul. But this very dualism is also monism: both bodies and souls are substances, as Aristotle said; and we can go farther than Aristotle. Men are apt to dwell too much on the coexistence and too little on the inclusiveness of substances. The fact is that many substances are often in one; *e.g.*, many bodies in the one body, and both body and soul in the one substance, of man. What is true of the microcosm is true of the macrocosm. There are many bodies in one earth; and there is no reason for stopping this inclusiveness short of one bodily universe, or for refusing to believe that with the omnipresent spiritual substance of God it forms one substantial universe, like a gorgeous palace containing many rooms and inhabitants, all under one master. So far true metaphysics is a monism of substance, in the sense both that all things are substances and that all substances, however different, are members of one substance, the whole universe of body and spirit. In this case metaphysics generally will have to recognize three monisms, a materialistic monism of body, an idealistic monism of soul, and a realistic monism of substance, which is also a dualism of substances. But a term so equivocal, leading to an antithesis so misleading as that between monism and dualism, can never represent the real difference between metaphysical schools. We shall return, then, to the clearer and more authoritative division, and proceed to discuss materialism, idealism, and realism in their order. Idealism will receive most attention, because it is the dominant philosophy of modern thought, which tries to dethrone Aristotle as Jupiter dethroned Saturn. But perchance *redeunt Saturnia regna.*

§ 2. RECENT MATERIALISM.

(1) *Materialism Proper.*—Materialism in its modern sense is the view that all we know is body, of which mind is an attribute or function. Several causes, beginning towards the end of the 18th century, gradually led up to the materialism which flourished in the middle of the 19th century in the writings of Moleschott, Vogt, and

Büchner. The first cause was the rapid progress of natural science. The chemistry of Lavoisier, and especially his discovery of the nature of combustion, from which followed that of respiration, gave fresh evidence to the old principle of the indestructibility of matter by bodily forces, and to the application of chemical laws to biology. The zoology of Lamarck, although his views were unpopular and condemned by the authority of Cuvier, yet weakened the old hypothesis of the immutability of species, and started the theory of evolution in the form of the hereditary transmission of modifications produced in organisms by use and adaptation to the environment. The astronomy of Laplace suggested the hypothesis that the regular motions of the bodies comprising the solar system might be explained by supposing that the atmosphere of the sun originally extended beyond the orbits of all the planets and had gradually contracted. The geology of Lyell continued, as it were, the evolution of the solar system by accumulating facts inclining him to believe that the forces now operating are similar to those which worked out geological revolutions, or that we may dispense with catastrophes, and regard ancient and present fluctuations of the organic and inorganic world as belonging to one series of events. These advances in natural science, which pointed to a unity and gradual evolution in nature, were accompanied by a growth in commerce, manufactures, and industrialism which tended to absorb men's minds in material interests; and it was the same kind of spirit which showed itself in the revolutionary upheaval of 1848, and in the materialistic publications which immediately followed, while these publications have reacted on the industrial socialism of our own time. Meanwhile, philosophic forces to counteract materialism were weak. Realism was at a low ebb. Idealism was receding for the moment. Hegelianism, which had for a time been converted into a kind of orthodox basis of State-education in Germany, had made itself unpopular. Its confusion of God, nature, and man had also led to differences within the school itself. Out of the Hegelians of the "left" arose not only David Strauss (1808-1874), but also Ludwig Feuerbach (1804-1872), who became the immediate forerunner of the materialists. Feuerbach's point against Hegel—not God, but man—made him a philosopher of humanity, like Comte, rather than a materialist. But he enunciated propositions which could not but lead to materialism, such as, "The body is part of my being; nay, the body is its totality, is my Ego," and "Man is what he eats," and "Man by himself is but man; man with man, the unity of 'I' and 'thou,' is God." These causes, then, scientific, industrial, and philosophical, led to the domination of materialism in the middle of the 19th century in Germany, or rather to its revival; for in its main position, that matter and motion are everything and eternal, it was a repetition of the materialism of the 18th century in France. Carl Vogt (1817-1895) was an instance of this revival. When in 1854 the physiologist Rudolf Wagner declared that an individual permanent *Seelensubstanz* is required, if not by physiology yet by morals, if not by science yet by faith, Vogt replied by turning the saying of the French physician Cabanis, "The brain is determined to thought as the stomach is to digestion, or the liver to the secretion of bile," into the offensive form, "Thought stands in the same relation to the brain as the bile to the liver or the urine to the kidneys." But recent materialism was not mere repetition. J. Moleschott (1822-1893) made a diligent use of the science of his day in his *Kreislauf des Lebens* (1852). Starting from Lavoisier's discoveries, he held that life is metabolism, a perpetual circulation of matter from the inorganic to the organic

world, and back again. He urged this metabolism against the hypothesis of vital force as then held by Liebig, but descending from antiquity in various forms. Aristotle had imputed to all living beings a soul, but to plants only in the sense of a vegetative, not a sensitive, activity. Stahl (1666-1734) changed Aristotle's vegetative into a sensitive soul, which he imputed to all living beings, and supposed that it is an incorporeal substance governing the body and its forces, as well as performing mental operations. Since Stahl's time the psychical side of his views has usually been either abandoned or modified, but in Moleschott's time many scientific men still accepted some sort of vital principle, not exactly soul, yet over and above bodily forces in organisms. Moleschott, like Lotze, had the merit of resisting the whole hypothesis of a vital principle, and in later editions of his work he supported his case by Berthelot's discoveries in artificially producing from the chemical elements organic substances. But he went farther. On the basis of Lavoisier's discovery that respiration is combustion, he argued that the heat so produced is the only force developed in the organism, and that matter therefore rules man. His saying, "Without phosphorus no thought," does not mean much; but he went on to the conclusion that thought is a movement of the matter of the brain. Finally, he put the whole materialistic view of the world into the following form: Without matter no force, without force no matter. L. Büchner (1824-1899) himself said that he owed to Moleschott the first impulse to composing his important work *Kraft und Stoff* (1855), which has run through many editions and become a kind of text of materialism. He borrowed from Moleschott the hypothesis that matter and force are inseparable. At the same time his originality consisted in his use of the theory of evolution. He applied Lyell's evolution of the earth's crust to the evolution of life upon it. In later editions, after the publication of the *Origin of Species* in 1859, he regarded Darwinism as the chief support of materialism, and asserted that the struggle for life and natural selection have abolished final causes. As in the sequel it became more and more patent that natural selection gives no account of the origin of variations, as proofs of the direct action of the environment on the species became more plentiful, so that Darwin himself in 1876 confessed that he had not attached sufficient weight to food, climate, &c., and as in consequence Lamarck's views revived in a neo-Lamarckian school, Büchner accepted the new theory, that Lamarckian adaptation to the environment hereditarily transmitted produces the variations which are the materials of Darwinian natural selection. His general inference was that, not God, but evolution of matter, is the cause of the order of the world; that life is a combination of matter which in favourable circumstances is spontaneously generated; that there is no vital principle, because all forces, non-vital and vital, are movements; that movement and evolution proceed from life to consciousness; that it is foolish for man to believe that the earth was made for him, in the face of the difficulties he encounters in inhabiting it; that there is no God, no final cause, no immortality, no freedom, no substance of the soul; and that mind, like light or heat, electricity or magnetism, or any other physical fact, is a movement of matter. Sometimes he spoke of mind as an effect of matter; but, though his expressions may be careless, nothing is to be made of the difference, for he called it movement and effect indifferently in the same context. His definitely expressed view was that psychical activity is "nothing but a radiation through the cells of the grey substance of the brain of a motion set up by external stimuli."

Belonging to a slightly later time than the materialists hitherto mentioned, E. Haeckel has lately published a

book which may be taken to represent materialism as it stands, *Die Weltrüthsel*, or, as it appears in the translation by J. McCabe, *The Riddle of the Universe*. The point of this book is the identification of substance with body. Starting like his predecessors with the indestructibility of matter, Haeckel makes more than they do of the conservation of energy, and merges the persistence of matter and energy in one universal law of substance, which, on the ground that body is subject to eternal transformation, is also the universal law of evolution. One of the first to popularize Darwin in Germany, he regards Darwinism, like Büchner, as a supplement of Lamarckism. His strong point, however, consists not in establishing either selection, or adaptation, or any other process, but in inferring the fact of evolution of some sort from the consideration of three evidences: comparative anatomy, showing the long-known graduated series of organisms; palæontology, showing their similar geological succession in a historical series; and embryology, showing the similar development of the organism from the impregnated ovum, expressed in the biogenetic law, "Ontogenesis is a brief and rapid recapitulation of phylogenesis." On the strength of this concilience of arguments for evolution in the organic world, he carries back the process in the whole world, until he comes to a cosmology, which reminds one of the rash hypotheses of the Presocratics. He supposes that all organisms have developed from the simple cell, and that this has its origin by spontaneous generation, to explain which he propounds the "carbon-theory," that protoplasm comes from inorganic carbonates. He not only agrees with Laplace and Lyell about the evolution of the solar system, but also supposes that the affinities, pointed out by Lothar Meyer and Mendeléeff, between groups of chemical elements prove an evolution of these elements from a primitive matter (prothyl) consisting of homogeneous atoms. These, however, are not ultimate enough for him; he thinks that everything, ponderable and imponderable or ether, is evolved from a primitive substance, which condenses first into centres of condensation (pyknotoms), and then into masses, which when they exceed the mean consistency become ponderables, and when they fall below it become imponderables. Here he stops: according to him, substance is eternal and eternally subject to the law of substance; and God is the eternal force or energy of substance. What then is the origin of mind or soul? Haeckel answers that it has no origin, because sensation is an inherent property of all substance. He supposes that *æsthesis* and *tropesis*, as rudimentary sensation and will, are the very causes of condensation; that they belong to *pyknotoms*, to ponderables and imponderables, to chemical atoms and molecules. Hence, when he returns to organisms, it does not surprise us that he assigns to ova and spermatozoa cell-souls, to the impregnated ovum germ-soul, to plants tissue-souls, to animals nerve-souls; or that he regards man's body and soul as born together in the impregnated ovum, and gradually evolved from the bodies and souls of lower animals. It appears to his imagination that the affinity of two atoms of hydrogen to one of oxygen, the attraction of the spermatozoon to the ovum, and the elective affinity of a pair of lovers, are all alike due to sensation and will. But has he solved the problems of mind? When he applies sensation and will to nature, and through plants to the lowest animals, he considers their sensation and will to be rudimentary and unconscious. Consciousness, according to his own admission, is not found even in all animals, although it is present not only in the highest vertebrates—men, mammals, birds—but also in ants, spiders, the higher crabs and molluscs. He holds indeed that, in accordance with the law of substance, consciousness must be evolved from unconsciousness with the

development of sense organs and a central nervous organ. At the same time he admits, first, that to mark the barrier between unconscious and conscious is difficult; secondly, that it is impossible to trace the first beginning of consciousness in the lower animals; and, thirdly, that "however certain we are of the fact of this natural evolution of consciousness, we are, unfortunately, not yet in a position to enter more deeply into the question" (*Riddle of the Universe*, 191). Thus in presence of the problem which is the crux of materialism, the origin of consciousness, he first propounds a gratuitous hypothesis that everything has mind, and then gives up the origin of conscious mind after all. He is certain, however, that the law of substance somehow proves that conscious soul is a mere function of brain, that soul is a function of all substances, and that God is the force or energy, or soul or spirit, of Nature. He, in fact, returns to ancient hylozoism, which has tended to revive from time to time in the history of thought. As Empedocles confused physical attraction and repulsion of bodily elements with the love and hatred of conscious beings, so Telesio and Campanella believed in the "sense of things," Bruno, an ardent admirer of the Presocratics, believed in animated *minima*, and Leibnitz after him endowed monads with perception and appetition. Maupertuis converted the percipient monads of Leibnitz into percipient atoms. Haeckel is the inheritor of these animistic views, and especially of the first and the last. He believes that mind and soul are inherent attributes of all bodies. Curiously enough, he supposes that by making mind a universal attribute of matter he has made his philosophy not materialism, but monism. It is really both: monistic, because it reduces substance to one kind; materialistic, because it identifies that one kind of substance with body or matter, and reduces mind to an attribute of matter. It makes no difference to attribute mind to all matter, so long as it is attributed as an attribute. It is at least as materialistic to say that unconscious mind is an attribute of Nature as to say that conscious mind is an attribute of brain; and this is the position of Haeckel. Materialists seem to dread the word "materialism." Büchner also entreats us "to abandon the word 'materialism,' to which (it is not clear why) a certain scientific odium attaches, and substitute 'monism' for it" (*Last Words on Materialism*, 273). His reason, however, is different: it is that a philosophy, not of matter as such, but of the unity of force and matter, is not materialism. But if a philosophy makes force an attribute of matter only, as his does, it will recognize nothing but matter possessing force, and will therefore be materialism as well as monism, and in short materialistic monism. The point is that neither Büchner nor Haeckel could on their assumptions recognize any force but force of body, or any mind but mind of body, or any distinct thing or substance except body. This is materialism.

(2) *Materialistic Tendencies*.—Besides these direct instances of materialism, there are philosophers to whom the scientific tendencies of the age have given a materialistic tendency. In Germany, for example, Eugen Dühring is a realist, whose intention is to prove against Kant a knowledge of the thing in itself by attributing time, space, and categories generally to the real world. But, under the influence of Trendelenburg's attempt to reconcile thought and being by assigning motion to both, his *Wirklichkeitsphilosophie*, in a similar effort after a unity of being, lands him in the contention that matter is absolute being, the support of all reality underlying all bodily and mental states. So R. Avenarius was no materialist, but only an empiricist anxious to reclaim man's natural view of the world from philosophic incrustations; yet when his *Empiriokriticismus* ends in

nothing but environment, nervous system, and statements dependent on them, without soul, though within experience, he comes near to materialism, as Wundt has remarked. In France, again, positivism is not materialism, but rather the refusal to frame a metaphysical theory. Comte, in his law of the three stages, tells us that man first gets over theology, then over metaphysics, and finally rests in positivism. Yet in getting over theology he ceases to believe in God, and in getting over metaphysics he ceases to believe in soul. As Paul Janet truly remarked, positivism contains an unconscious metaphysics in rejecting final causes and an immaterial soul. So E. Littré (1801-1881), Comte's disciple, said that soul signifies "considered anatomically the *ensemble* of functions of the brain, and considered physiologically the *ensemble* of functions of encephalic sensibility." He also took Mill to task for recognizing the possibility of a supernatural principle of the world. Now, when in surrendering theology and metaphysics we have also to surrender God and the soul, we are not free from materialism. Positivism, however, shelters itself behind the vague word "phenomena." Lastly, in England we have not only an influence of positivism, but also, what is more important, the synthetic philosophy of Herbert Spencer. The point of this philosophy is not materialism, but realism. The author himself says that it is transfigured realism—which is realism in asserting objective existence as separate from subjective existence, but anti-realism in denying that objective existence is to be known. In his *Principles of Psychology* he twice quotes his point that "what we are conscious of as properties of matter, even down to its weight and resistance, are but subjective affections produced by objective agencies which are unknown and unknowable." This then is his transfigured realism, which, as far as what is known goes, is idealism, but as far as what exists goes, realism—of a sort. His *First Principles*, that is, his book on metaphysics, is founded on this same point, that what we know is phenomena produced by an unknown noumenal power. He himself identifies phenomenon, appearance, effect, or impression produced on consciousness through any of the senses. He divides phenomena into impressions and ideas, vivid and faint, object and subject, non-ego and ego, outer and inner, physical and psychical, matter and spirit; all of which are expressions of the same antithesis among phenomena. He holds that all the time, space, motion, matter known to us are phenomena; and that force, the ultimate of ultimates, is, as known to us, a phenomenon, "an affection of consciousness." If so, then all we know is these phenomena, affections of consciousness, subjective affections, but produced by an unknown power. So far as this main point of transfigured realism is steadily maintained, it is a compound of idealism and realism, but not materialism. But it is not maintained, on the side either of phenomena or of noumena; and hence its tendency to materialism.

In the first place, the term "phenomenon" is ambiguous, sometimes meaning a conscious affection, and sometimes any fact whatever. Spencer sets himself to find the laws of all phenomena. He finds that throughout the universe there is an unceasing redistribution of matter and motion, and that this redistribution constitutes evolution when there is a predominant integration of matter and dissipation of motion, and constitutes dissolution where there is a predominant absorption of motion and disintegration of matter. He supposes that evolution is primarily integration, from the incoherent to the coherent, exemplified in the solar nebula evolving into the solar system; secondly differentiation, from the more homogeneous to the more heterogeneous, exemplified by the solar system evolving into different bodies;

thirdly determination, from the indefinite to the definite, exemplified by the solar system with different bodies evolving into an order. He supposes that this evolution does not remain cosmic, but becomes organic. In accordance with Lamarck's hypothesis, he supposes an evolution of organisms by hereditary adaptation to the environment (which he considers necessary to natural selection), and even the possibility of an evolution of life, which, according to him, is the continuous adjustment of internal to external relations. Next, he supposes that mind obeys the same law of evolution, and exemplifies integration by generalization, differentiation by the development of the five senses, and determination by the development of the order of consciousness. He holds that we pass without break from the phenomena of bodily life to the phenomena of mental life; that consciousness arises in the course of the living being's adaptation to its environment, and that there is a continuous evolution from reflex action through instinct and memory up to reason, an evolution of social institutions, and an evolution of conscience out of fear. He throws out the brilliant suggestion that the experience of the race is in a sense inherited by the individual; which is true in the sense that animal organisms become hereditarily better adapted to perform mental operations, though no proof that any elements of knowledge become *a priori*. Now, although in his enthusiasm for universal evolution Spencer does not perceive it, he has clearly changed the meaning of the term "phenomenon" from subjective affection of consciousness to any fact of nature, in regarding all this evolution, cosmic, organic, mental, social, and ethical, as an evolution of phenomena. The greater part of the process is a change in the facts of nature before consciousness; and in all that part, at all events, the phenomena evolved must mean physical facts which are not conscious affections, but, as they develop, are causes which gradually produce life and consciousness. Moreover, evolution is defined universally as an "integration of matter and dissipation of motion," and yet mental, social, and moral developments are also called evolution, so that, in accordance with the definition, they are also integrations of matter and dissipations of motion. It is true that the author did not see that he was passing from transfigured realism into materialism. He thinks that he is always speaking of phenomena in the sense of subjective affections; and in spite of his definition, he half unconsciously changes the meaning of evolution from a change in matter and motion, first into a change in states of consciousness, then to a change in social institutions, and finally into a change in moral motives. He also admits himself that mental evolution exemplifies integration of matter and dissipation of motion only indirectly. But here he becomes hopelessly inconsistent, because he had already said, in defining it, that, "*evolution is an integration of matter and concomitant dissipation of motion*" (*First Principles*, § 145). However, with all the author's disclaimers, the general effect left on the reader's mind is that throughout the universe there is an unceasing change of matter and motion, that evolution is always such a change, that it begins with phenomena in the sense of physical facts, gradually issues in life and consciousness, and ends with phenomena in the sense of subjective affections of consciousness.

In the second place, having declared the noumenal power, which causes phenomena, or conscious affections, to be unknowable, and having left anybody who pleased to make it a god and an object of religion, he proceeds to describe it as if it were known force, and known in two respects as persistent and as resistant force. He supposes that the law of evolution is deducible from the law of persistent force, and includes in force what is now called energy. Then

having discussed force as something thoroughly material, and laying special emphasis on resistance, he tells us that "the force of which we assert persistence is that Absolute Force of which we are indefinitely conscious as the necessary correlate of the force we know" (*First Principles*, § 62). Similarly, both in *First Principles* and in the *Principles of Psychology*, he assigns to us, in addition to our definite consciousness of our subjective affections, an indefinite consciousness of something out of consciousness, of something which resists, of objective existence. Thus it turns out that the objective agency, the noumenal power, the absolute force, declared unknown and unknowable, is known after all to exist, persist, resist, and cause our subjective affections or phenomena, yet not to think or to will. Such a noumenon looks very like body or matter. Lastly, when a theory of the world supposes a noumenal power, a resistant and persistent force, which results in an evolution, defined as an integration of matter and a dissipation of motion, which having resulted in inorganic nature and organic nature, further results without break in consciousness, reason, society, and morals, then such a theory will be construed as materialistically as that of Haeckel by the reader, whatever the intention of the author.

It may be urged in reply that the synthetic philosophy could be made consistent by transferring the knowable resistance and persistence of the unknowable noumenon to knowable phenomena on the one hand, and on the other hand by maintaining that all phenomena from the original nebula to the rise of consciousness are only "impressions produced on consciousness through any of the senses," after all. But in that case what will become of Spencer's theory of evolution? It will have asserted the evolution of man and his consciousness out of the phenomena of his consciousness. The truth is that his theory of evolution can be carried through the whole process from inorganic, through organic, to mental and moral facts, without a break, only by giving the synthetic philosophy a materialistic interpretation, and by adhering consistently to Spencer's own materialistic definition of evolution; otherwise there will be a break at least between life and mind, where there will be something more than matter and motion to be redistributed. If everything knowable is an example of evolution, and evolution is by definition a transformation of matter and motion, then everything knowable is an example of a transformation of matter and motion. As an exponent of universal evolution Haeckel is more consistent than Spencer. Huxley (1825-1895) developed views very like those of Spencer, and similarly materialistic without being materialism, because inconsistent. He regarded everything known as evolved from matter, and reduced consciousness to a mere collateral product (or "epiphenomenon") of cerebral operations without any power of influencing them. Matter, according to him, impresses the afferent nervous system, this the brain, this the efferent nervous system, while consciousness remains a mere spectator. "In man, as in brutes," said he, "there is no proof that any state of consciousness is the cause of change in the nature of the matter of the organism"; so that "we are conscious automata." But, in spite of these materialistic tendencies, he followed Hume in reducing matter and everything knowable to phenomena of consciousness; and, supposing that nothing is knowable beyond phenomena, concluded that we can neither affirm nor deny that anything exists beyond, but ought to take up an attitude which the ancient sceptics called Apathia, but he dubbed by the new name of Agnosticism. Thus Huxley first reduced consciousness to a product of matter, and then matter to a phenomenon of consciousness. By combining materialism with idealism he made consciousness a product of itself. Tyndall (1820-1893), again, came still nearer to material-

ism, and yet avoided it. In his Belfast address (1874), while admitting that matter as understood by Democritus is insufficient, because atoms without sensation cannot be imagined to produce sensation, he contended, nevertheless, that matter properly understood is "the promise and potency of all terrestrial life." In thus endowing all matter with sensation like Haeckel he was not avoiding materialism. But in the very same address, as well as on other occasions, he did not identify mind with matter, but regarded them as concomitant.

All these materialistic tendencies seem to have one explanation. They emanate from scientific writers who rightly try to rise from science to metaphysics, but, as Bacon says, build a universal philosophy on a few experiments. The study of evolution, without considering how many conditions are required for "the integration of matter and the dissipation of motion" to begin, and the undoubted discoveries which have resulted from the study of inorganic and organic evolution, have led men to expect too much from this one law of nature. This tendency especially prevails in the uncertain science of biology, which is so far off the general principles of natural philosophy that its votaries are often ignorant of the real nature of body as matter and force. The close dependency of all mental operations on brain also tempts them to the conclusion that brain is not only an organ, but the whole organ of conscious mind. We may see traces of this tendency in the writings of H. Maudsley, in his lecture, for example, on *Lessons of Materialism* (1879). It appears also that Darwin, having extended his theory of evolution as far as the rational and moral nature of man, in the *Descent of Man*, ended in his *Autobiography* by declaring his attitude to first and final causes to be that of an agnostic. Not that he was a materialist, and shortly before his death, in a conversation with Büchner, he maintained his agnosticism against his opponent's atheism. Still, his agnosticism meant that, though he did not assert that there is no God, he did assert that we cannot know whether there is or there is not. To the evolutionary biologist brain is apt to appear to be the crowning object of knowledge. On the other hand, those scientific men, such as Herschel, Maxwell, and Stokes, who approach nature from mathematics and mechanics, and therefore from the universal laws of motion, have the opposite tendency, because they perceive that nature is not its own explanation. In order to exert force, or at all events that force of reciprocal pressure which we best understand, and on which, in impact, the third law of motion was founded, there are always at least two bodies, enduring, triply extended, mobile, each inert, mutually impenetrable or resistant, different yet similar; and in order to have produced any effect but equilibrium, some bodies must at some time have differed either in mass or in velocity, otherwise forces would only have neutralized one another. Why do bodies exist, with all these conditions, so similar yet different—that is, in so harmonious an order? Natural science has no answer: natural theology has an answer. This essence of bodies, this resemblance in difference, this prevailing order of nature, is the deepest proof of God; and it cannot be the result of evolution, because it is the condition of natural force, and therefore of natural evolution. A second argument for God is the prevailing goodness or adaptation of nature to the ends of conscious beings, which might conceivably be explained by Lamarckian evolution, but has not yet been so explained, and if it were, would not be inconsistent with a divine design in evolution. Further, the very existence of conscious beings is the best proof of the distinct or substantial being of the soul, existing in man with body, in God as pure spirit. It seems hopeless to expect that natural science, even with

the aid of evolution, can explain by mere body the origin and nature of this fact of consciousness. If so, materialism is not the whole truth of metaphysics.

§ 3. THE RISE OF METAPHYSICAL IDEALISM.

(1) *Descartes to Leibnitz*.—Metaphysical arises from psychological idealism, and always retains more or less of an epistemological character. Psychological idealism assumes without proof that we perceive nothing but mental objects, and metaphysical idealism draws the logical but hypothetical conclusion that all we can know from these mental objects of sense is mental objects of knowledge. But at first this logical conclusion was not drawn. Descartes, the founder of psychological idealism, having proceeded from the conscious fact, *cogito ergo sum*, to the *non-sequitur* that I am a soul, and all a soul can perceive is its ideas, nevertheless went on to the further illogical conclusion that from these mental ideas I can (by the grace of God) infer things which are extended substances or bodies, as well as thinking substances or souls. He was a psychological idealist and a metaphysical realist. This illogicality could not last. Even the Cartesian school, as it came more and more to feel the difficulty of explaining the interaction of body and mind, and, indeed, any efficient causation whatever, gradually tended to the hypothesis that the real cause is God, who, on the occasion of changes in body, causes corresponding changes in mind, and *vice versa*. This occasionalism is not idealism, but its emphasis on the will of God gave it an idealistic tendency. Thereupon Spinoza advanced a pantheism which supposed that bodies and souls are not, as Descartes thought, different substances, but merely attributes—the one the extension and the other the thought of one substance, Nature or God. Taking the Aristotelian theory that a substance is a thing in itself, not in Aristotle's sense of any individual existing differently from anything else, but in the novel meaning of something existing alone, he concluded, logically enough from this mere misunderstanding, that there can be only one substance, and that, as no finite body or soul can exist alone, everything finite is merely a mode of one of the attributes of the one infinite substance which alone can exist by itself. Spinozism, however, though it tramples down the barrier between body and soul, is not yet metaphysical idealism, because it does not reduce extension to thought, but only says that the same substance is at once extended and thinking—a position more akin to materialism. At the same time Spinoza maintained a parallelism between extension and thinking so close as to say that the order of ideas is the same as the order of things, so that any mode of extension and the idea of it are the same thing expressed in two ways, under the attribute of extension and under the attribute of thought. (See H. H. Joachim's *Study of the Ethics of Spinoza*, 1901, p. 72.) It remained, however, for Schelling to convert this parallelism into identity by identifying motion with the intelligence of God, and so to transform the pantheism of Spinoza into pantheistic idealism. Leibnitz, again, having become equally dissatisfied with Cartesianism, Spinozism, and the Epicurean realism of Gassendi, whom he had first followed in analysing nature into atoms and vacuum, in the latter part of his life came still nearer than Spinoza to metaphysical idealism in his monadology, or half-Pythagorean, half-Brunistic analysis of bodies into monads, or units, or simple substances, indivisible and unextended, but endowed with perception and appetite. He gradually fell under the dominion of two false assumptions. On the one hand, essentially a mathematician, he supposed that unity is indivisibility, whereas everything known to be one is merely undivided or individual, and that there

must be simple because there are compound substances, although composition only requires simpler or relatively simple elements. On the other hand, under the influence of the mechanics of his day, which had hardly distinguished between inertia, or the inability of a body to change itself, and resistance, or the ability of bodies to oppose one another, he concluded that, as inertia is passive, so is resistance, and refused to recognize that in collision the mutual resistance of moving bodies is a force, or active power, of changing their movements in opposite directions. From these two arbitrary hypotheses about corporeal motion, that it requires indivisibly simple elements, and that it offers only passive resistance, he concluded that behind bodies there must be units, or monads, which would be at once substantial, simple, indivisible, and active. He further supposed that the monads are "incorporeal automata," not interacting like bodies, but each perceiving what was passing in the other, and acting in consequence by appetite, or self-acting. Such mentally endowed substances might be called souls; but, as he distinguished between perception and apperception or consciousness, and considered that perceptions are often unconscious, he preferred to divide monads into unconscious entelechies of inorganic bodies, sentient souls of animals, and rational souls, or spirits, of men; while he further concluded that all these are derivative monads created by God, the monad of monads. All derivative monads, he allowed, are accompanied by bodies, which, however, are composed of other monads dominated by a central monad. Further, he explained the old Cartesian difficulty of the relation of body and mind by transforming the Spinozistic parallelism of extension and thought into a parallelism between the motions of bodies and the perceptions of their monads; motions always proceeding from motions, and perceptions from perceptions; bodies acting according to efficient causes, and souls according to final causes by appetite, and as if one influenced the other without actually doing so. Finally, he explained the concomitance of these two series, as well as that between the perceptions of different monads, by supposing a pre-established harmony ordained by the primitive monad, God. Up to this point, then, Leibnitz opened one of the chief avenues to metaphysical idealism, the resolution of the material into the immaterial, the analysis of bodies into mental elements. Like the Pythagoreans, he regarded bodies as composed of units; unlike them, he endowed these units with minds. He followed Bruno's dogma—"Spirto si trova in tutte le cose, e non è minimo corpusculo, che non contegna cotal porzione in sè, che non inanimi" (*Della causa*). His theory of bodies involved an idealistic analysis neither into bodily atoms, nor into mathematical units, but into mentally endowed simple substances. There remained, however, his theory of the nature of bodies; and here he hesitated between two alternatives. According to one alternative, which consistently flowed from the psychological idealism of Descartes, as well as from his own monadism, he suggested that bodies are real phenomena; phenomena, because they are aggregates of monads, which derive their unity only from appearing together to our perceptions; real phenomena well founded, because they result from real monads. In support of this view, he said that bodies are not substances, though *substantiata*; that their apparent motion and resistance are results of the passions of their monads; that their primary matter is nothing but passive power of their monads; that the series of efficient causes between them is merely phenomenal. According to this alternative, then, there is nothing but mental monads and mental phenomena; and Leibnitz is a metaphysical idealist. According to the other alternative, however, he suggested

that at least organic bodies are compound or corporeal substances, which are not phenomena, but something realizing or rather substantializing phenomena; and not mere aggregates of monads, but something substantial beyond their monads, because an organic body, though composed of monads, has a real unity (*unio realis*). From this point of view he believed that the real unity of a body is a *vinculum substantiale*, which gives it its real continuity and is the principle of its actions; that its primary matter is its own principle of resistance; and that it has not only this passive, but also an active, power of its own. He suggested that this theory of the substantial unity of a body might explain transubstantiation, by supposing that, while the monads and phenomena of bread remain, the *vinculum substantiale* of the body of Christ is substituted. He feared also whether we can explain the mystery of the Incarnation, and other things, unless real bonds or unions are added to monads and phenomena. According to this alternative, these organic bodies are compound or corporeal substances, between monads and phenomena; and Leibnitz is a metaphysical realist. He was held to this belief in the substantiality of bodies by his Christianity, by the influence of Aristotle, of scholasticism, and of Cartesianism, as well as by his own mechanics. But the strange thing is that at the very end of his life and at the very same time, in 1714-16, he was writing the idealistic alternative to Remond de Montmort and Dancicourt, and the realistic alternative to Father des Bosses. He must have died in doubt. We cannot, therefore, agree with many recent idealists who regard Leibnitz as one of themselves, though it is true that, when stripped of its realism, his metaphysics easily passed into the metaphysical idealisms of Lotze and of Fechner. It is true, also, that on its idealistic side the philosophy of Leibnitz is the source of many current views of panpsychism, of psychophysical parallelism, as well as of the phenomenalism of bodies, and of the analysis of bodies into mental elements.

(2) *Locke to Hume*.—Meanwhile in England, Locke, though differing from Descartes about the origin of ideas, followed him in the illogical combination of psychological idealism with metaphysical realism. He thought that we perceive nothing but ideas both of primary and of secondary qualities, and yet that somehow we are able to infer that, while our ideas of secondary qualities are not, those of primary qualities are, like the real qualities of external things. Berkeley saw the inconsistency of this position, and, in asserting that all we perceive and all we know is nothing but ideas in "mind, spirit, soul, or myself," has the merit of having made, as Paulsen remarks, "epistemological idealism the basis of metaphysical idealism." According to him, a body such as the sun is my idea, your idea, ideas of other minds, and always an idea of God's mind; and when we have sensible ideas of the sun, what causes them to arise in our different minds is no single physical substance, the sun, but the will of God's spirit. Hume saw that in making all the objects of perception ideas Berkeley had given as little reason for inferring substantial souls as substantial bodies. He therefore concluded that all we know from the data of psychological idealism is impressions or sensations, ideas, and associations of ideas, making us believe without proof in substances and causes, together with "a certain unknown, inexplicable *something* as the cause of our perceptions." We have here, in this sceptical idealism, the source of the characteristically English form of idealism, still to be read in the writings of Mill and Spencer, and still the starting-point of more recent works, such as Pearson's *Grammar of Science* and James's *Principles of Psychology*.

(3) *Kant and Fichte*.—Lastly, in Germany, partly influenced by Leibnitz and partly roused by Hume, Kant

elaborated his transcendental or critical idealism, which, if not, as he thought, the prolegomena to all future metaphysics, is still the starting-point of most metaphysical idealists. Kantism consists of four main positions, which it will be well to lay out, as follows:—

(a) As to the origin of knowledge, Kant's position is that sense, outer and inner, affected by things in themselves, receives mere sensations or sensible ideas (*Vorstellungen*), as the matter which sense itself places in the *à priori* forms of space and time; that thereupon understanding, by means of the synthetic unity of apperception, "I think"—an act of spontaneity beyond sense, in all consciousness one and the same, and combining all my ideas as mine in one universal consciousness—and under *à priori* categories, or fundamental notions, such as substance and attribute, cause and effect, &c., unites groups of sensations or sensible ideas into objects and events, e.g., a house, one ball moving another; and that, accordingly, perception and experience, requiring both sense and understanding, are partly *à posteriori* and partly *à priori*, and constitute a knowledge of objects which, being sensations combined by synthetic unity under *à priori* forms, are more than mere sensations, but less than things in themselves. This first position is psychological idealism in a new form and supported by new reasons; for, if experience derives its matter from mental sensations and its form from mental synthesis of sensations, it can apprehend nothing but mental objects of sense, which, according to Kant, are sensible ideas having no existence outside our thought, not things in themselves; or *phenomena*, not *noumena*.

(b) As to the known world, Kant's position was the logical deduction that from such phenomena of experience all we can know by logical reason is similar phenomena of actual or possible experience; and therefore that the known world, whether bodily or mental, is not a Cartesian world of bodies and souls, nor a Spinozistic world of one substance, nor a Leibnitzian world of monadic substances created by God, but a world of sensations, such as Hume supposed, only combined, not by association, but by synthetic understanding into phenomenal objects of experience, which are phenomenal substances and causes—a world of phenomena, not noumena. This second position is a new form of metaphysical idealism, containing the supposition, which lies at the foundation of later German philosophy, that since understanding shapes the objects out of sensations, and since nature, as we know it, consists of such objects, "understanding, though it does not make, shapes nature," as well as our knowledge. Known nature is a mental construction in part, according to Kant.

(c) As to existence, Kant's position is the wholly illogical one that, though all known things are phenomena, there are things in themselves, or noumena; things which are said to cause sensations of outer sense and to receive sensations of inner sense, though they are beyond the category of causality which is defined as one of the notions uniting phenomena; and things which are assumed to exist and have these causal attributes, though declared unknowable by any logical use of reason, because logical reason is limited by the mental matter and form of experience to phenomena; and all this according to Kant himself. This third position is a relic of ancient metaphysical realism; although it must be remembered that Kant does not go to the length of Descartes and Locke, who supposed that from mere ideas we could know bodies and souls, but suggests that beneath the phenomena of outer and inner sense the thing in itself may not be heterogeneous (*ungleichartig*). In this form we shall find the thing in itself revived in our day by A. Riehl.

(d) As to the use of reason beyond knowledge, Kant's

position is that, in spite of its logical inability to transcend phenomena, reason in its pure, or *à priori* use, contains necessary *à priori* "ideals" (*Ideen*), and practical reason, in order to account for moral responsibility, frames postulates of the existence of things in themselves, or noumena, corresponding to these "ideals"; postulates of a real free-will to practise morality, of a real immortality of soul to perfect it, and of a real God to crown it with happiness. This fourth position is the coping-stone of Kant's metaphysics. It is quite inconsistent with its foundation and structure. Kant first deduced that from the experience of mental phenomena all logical use of reason is limited to mental phenomena, and then maintained that to explain moral responsibility practical reason postulates the existence of real noumena. But what is a postulate of practical reason to explain moral responsibility except a logical use of reason? Nevertheless, in his own mind Kant's whole speculative and practical philosophy was meant to form one system. In the preface to the second edition of the *Kritik* he says that it was necessary to limit speculative reason to a knowledge of phenomena, in order to allow practical reason to proceed from morality to the assumption of God, freedom, and immortality, existing beyond phenomena: "Ich musste also das *Wissen* aufheben, um zum *Glauben* Platz zu machen." He forgot that he had also limited all logical use of reason, and therefore of practical reason, to phenomena, and thereby undermined the rationality not only of knowledge, but also of faith.

Fichte now set himself in the *Wissenschaftslehre* (1794) to make transcendental idealism into a system of metaphysical idealism without Kant's inconsistencies and relics of realism. His point was that there are no things in themselves different from minds or acting on them; that man is no product of things; nor does his thinking arise from passive sensations caused by things; nor is the end of his existence attainable in a world of things; but that he is the absolute free activity constructing his own world, which is only his own determination, his self-imposed limit, and means to his duty which allies him with God. In order to prove this novel conclusion, he started afresh from the Cartesian "I think" in the Kantian form of the synthetic unity of apperception acting by *à priori* categories; but, instead of allowing, with all previous metaphysicians, that the Ego passively receives sensations from something different, whether bodies, or monads, or God, or an unknown thing in itself, and not contenting himself with Kant's view that the Ego, by synthetically combining the matter of sensations with *à priori* forms, partially constructs objects, and therefore Nature as we know it, he boldly asserted that the Ego, in its synthetic unity, entirely constructs things; that its act of spontaneity is not mere synthesis of passive sensations, but construction of sensations into an object within itself; and that therefore understanding makes as well as shapes Nature, as the Ego in thinking constructs both its own knowledge and its own world. This construction, or self-determination, is what Fichte called positing (*setzen*). According to him, the Ego posits first itself (thesis); secondly, the non-Ego, the other, opposite to itself (antithesis); and, thirdly, this non-Ego within itself (synthesis), so that all reality is in consciousness. But, he added, as the Ego is not conscious of this self-determining activity, but forgets itself, the non-Ego seems to be something independent, a foreign limit, a thing in itself, or *per se*. Hence it is the office of the theory of knowledge to show that the Ego posits the thing *per se* as only existing for itself, a *noumenon* in the sense of a product of its own thinking. Further, according to Fichte, on the one hand the Ego posits itself as determined through the non-Ego—no ob-

ject, no subject; this is the principal fact about theoretical reason; on the other hand, the Ego posits itself as determining the non-Ego—no subject, no object; this is the principal fact about practical reason. Hence he united theoretical and practical reason, which Kant had separated, and both with will, which Kant had distinguished; for he held that the Ego, in positing the non-Ego, posits both its own limit and its own means to the end, duty, by its activity of thinking which requires will. The conclusion of his epistemology is that we start with ourselves positing subjective sensations—*e.g.*, sweet, red—and refer them as accidents to matter in space, which, though mental, is objective, because its production is grounded on a law of all reason. The metaphysics resulting from this epistemology is that the so-called thing in itself is not a cause of our sensations, but a product of one's own thinking, a determination of the Ego, an object, limit, and means to the end of the Ego, a thing known to the Ego which constructs it. Fichte thus transformed the transcendental idealism of Kant by identifying the thing with the object, and by interpreting noumenon, not in Kant's sense of something which speculative reason conceives and practical reason postulates to exist in accordance with the idea, but in the new meaning of a thought, a product of reason. This change led to another. Kant had said that the synthetic unity "I think" is in all consciousness one and the same, meaning that I am always present to all my ideas. Fichte transformed this unity of the conscious self into a unity of all conscious selves, or a common consciousness; and this change enabled him to explain the unity of anything produced by the Ego by contending that it is not the different objects of different thinkers, but the one object of a pure Ego or consciousness common to them all. According to Kant, the objective is valid for all consciousnesses; according to Fichte, it is valid for one consciousness. Here he was for the first time grappling with a fundamental difficulty in metaphysical idealism which is absent from realism, namely, the difficulty of explaining the identity of a thing, *e.g.*, the sun. As long as even the meagre realism of the Kantian thing in itself is maintained, the account of there being one sun is simply that one thing causes different phenomena in different minds. But as soon as the thing in itself is converted into something mental, metaphysical idealists must either say that there are as many suns as minds, or that there is one mind and therefore one sun. The former was the alternative of Berkeley, the latter of Fichte. In fact, Fichte differed from Berkeley, as from Kant, in two respects. In the first place, while Berkeley said that God, and Kant that an unknown thing, is the cause of our sensations, Fichte said that we posit the sensations and the thing, and falsely regard the thing as the cause of sensations, until the theory of knowledge shows that it is only a mental product and a noumenon in this sense. Secondly, while Berkeley supposed that there might be as many suns as ideas, and Kant that an unknown thing causes many appearances of the sun in many minds, Fichte said that there is one mind positing one sun, a single pure Ego positing a single mental object, one and the same in all human persons. Thus the complete metaphysical idealism of Fichte's *Wissenschaftslehre*, formed out of the incomplete metaphysical idealism of Kant's *Kritik*, is the theory on its epistemological side that the Ego posits the non-Ego as a thing in itself, and yet as only a thing existing for it as its own noumenon, and on its metaphysical side that in consequence all reality is the Ego and its own determinations, which are objective, or valid for all, as determinations, not of you or of me, but of the consciousness common to all of us, the pure or absolute Ego. Lastly, Fichte called this system realism, in so far as it posits the thing in itself as another thing;

idealism, in so far as it posits it as a noumenon which is a product of its own thinking; and on the whole real idealism or ideal realism.

God does not seem to find much place in the *Wissenschaftslehre*, where mankind is the absolute and nature mankind's product, and where God neither could be an absolute Ego which posits objects in the non-Ego to infinity without ever completing the process, nor could be even known to exist apart from the moral order which is man's destination. Hence in his *Philosophical Journal* in 1798 Fichte prefaced a sceptical essay of Forberg by an essay of his own, in which he used the famous words, "The living moral order is God; we need no other God, and can comprehend no other." Having, however, in consequence, lost his professorship at Jena, he gradually altered his views, until at length he decided that God is not mere moral order, but also reason and will, yet without consciousness and personality; that not mankind but God is the absolute; that we are only its direct manifestations, free but finite spirits destined by God to posit in ourselves Nature as the material of duty, but blessed when we relapse into the absolute; that Nature, therefore, is the direct manifestation of man, and only the indirect manifestation of God; and, finally, that being is the divine idea or life, which is the reality behind appearances. In this extension of metaphysical idealism he was influenced by his disciple, Schelling. Nevertheless, he refused to go as far as Schelling, and could not bring himself to identify either man or nature with Absolute God. He wanted to believe in the absolute without sacrificing personality and freedom. God determines man, and man determines Nature: this is the final outcome of Fichte's pure idealism.

Fichte completed the process from psychological and epistemological to metaphysical idealism, which it has been necessary to recall from its beginnings in France, England, and Germany, in order to understand present idealism, which derives its original inspiration from the past and immediately from Spinoza and Leibnitz, Berkeley and Hume, Kant and Fichte. The assertion of absolute substance by Spinoza incited Schelling and Hegel. The analysis of bodies into immaterial elements by Leibnitz incited Lotze. The Spinozistic parallelism of extension and thought, and the Leibnitzian parallelism of bodily motion and mental action, incited Schelling and Fechner. Berkeley and Hume produced the English idealism of Mill and Spencer, with their successors, and occasioned the German idealism of Kant. Kant's *à priori* synthesis of sensations into experience lies at the root of all German idealism. But Fichte was the most fertile of all. He carried metaphysical idealism to its height, by not only resolving the bodily into the mental, but also elevating the action of mind into absolute mental construction; not inferring things in themselves beyond, but originating things from within, mind itself. By changing the meaning of "noumenon" from the thing apprehended (*νοούμενον*) to the thought (*νόημα*), and in the hypothesis of a common consciousness, he started the view that a thing is not yours or my thought, but a common thought of all mankind, and led to the wider view of Schelling and Hegel that the world is an absolute thought of infinite mind. In making the essence of mind activity and construction, in destroying the separation of theoretical and practical reason, in asserting that mind thinks things as means to ends of the will, he prepared the way for Schopenhauer and other voluntarists. In making the essence of the Absolute not mere reason, but will, action, and life, he anticipated Lotze. In reducing the thing in itself to a thought, he projected the neo-Kantism of Lange and Cohen. In the doctrine—no object, no subject—no subject, no object—that is, in

the utter identification of things with objects of subjects, he anticipated not only Schelling and Hegel, but also Schuppe and Wundt with their congeners. In expanding Kant's act of synthesis till it absorbed the inner sense and the innermost soul, he started the modern paradox that soul is not substance, but subject or activity, a paradox which has been gradually handed down from Schelling and Hegel to Fechner, and from Fechner to Paulsen and Wundt. Meanwhile, through holding with Kant that man is not God, but a free spirit, whose destiny it is to use his intelligence as a means to his duty, he is still the resort of many who vindicate man's independence, freedom, conscience, and power of using nature for his moral purposes: such, for example, are Eucken and Münsterberg. Kant and Fichte together became the most potent philosophic influences on European thought in the 19th century, because their emphasis was on man. They made man believe in himself and his mission. They fostered liberty and reform, and even radicalism. They almost avenged man on the astronomers, who had shown that the world is not made for earth, and therefore not for man. Kant half asserted, and Fichte wholly, that nature is man's own construction. The *Kritik* and the *Wissenschaftslehre* belonged to the revolutionary epoch of the "Rights of Man," and produced as great a revolution in thought as the French Revolution did in fact. Instead of the old belief that God made the world for man, philosophers began to fall into the pleasing dream, I am everything, and everything is I—and even I am God.

§ 4. NOUMENAL IDEALISM IN GERMANY.

Noumenal idealism is the metaphysics of those who suppose that all known things are indeed mental, but not all are phenomenal in the Kantian sense, because a noumenon is knowable so long as by a noumenon we mean some mental being or other which we somehow can discover beyond phenomena. The noumenal idealists of Germany assumed, like all psychological idealists, the unproved hypothesis that there is no sense of body, but there is a sense of sensations; and they usually accepted Kant's point, that to get from such sensations to knowledge there is a synthesis contributing mental elements beyond the mental data of sense. They saw also the logic of Kant's deduction, that all we can know from such mental data and mental categories must also be mental. This was the starting-point of their metaphysical idealism. But they disagreed with Kant, and agreed with Fichte about things in themselves or noumena, and contended that the mental things we know are not mere phenomena of sense, but noumena, precisely because noumena are as mental as phenomena, and therefore can be known from similar data: this was the central point of their noumenal idealism. They rightly revolted against the inconsistencies of Kant's third and fourth positions about the existence of unknown but postulated things in themselves, hidden from theoretical, but revealed to practical, reason. In a way they returned to the wider opinions of Aristotle, which had come down to Descartes and Locke, that reason in going beyond sense knows more things than phenomena; yet they would not hear of external bodies, or of bodies at all. No realists, they came nearer to Spinozistic pantheism and to Leibnitzian monadism, but only on their idealistic side; for they would not allow that extension and body are different from thinking and mind. In this denial of all bodily substances and all bodily attributes they were anticipated by Berkeley's view that when we get beyond ourselves we find nothing but other minds and ideas. But their real founder was Fichte, on account of his definite reduction of the noumenal to a mental world. This was indeed the very point—the knowability of a

noumenal mental world. At the same time it soon appeared that they could not agree among themselves when they came to ask what it is, but in attempting to define it seem to have gone through the whole gamut of mind. Schelling and Hegel thought it was infinite reason; Schopenhauer, unconscious will; Hartmann, unconscious intelligence and will; Lotze, the activity or life of the divine spirit; Fechner, who has been followed by Paulsen, a world of spiritual actualities comprised in the one spiritual actuality, God, in whom we live and move and have our being.

(1) *Schelling and Hegel.*—Of these noumenal idealisms the earliest in time and the nearest to Fichte's philosophy was the panlogism, begun by Schelling (1775–1854), completed by his disciple Hegel (1770–1831), and then modified by the master himself. Starting from Fichte's *Wissenschaftslehre*, Schelling accepted the whole process of mental construction, and the deduction that noumena are knowable products of universal reason, the Absolute Ego. But from the first he was bolder than Fichte, and had no doubt that the Absolute is God. God, as he thought, is universal reason, and Nature a product of universal reason, a direct manifestation, not of man, but of God: *Deus mundus implicitus; mundus Deus explicitus*. While Fichte emphasized man, Schelling emphasized Nature, and made a *Naturphilosophie*, which, extravagant as it was, yet had the merit of rising beyond the narrow relation of Nature to mere man up to the universal relation of Nature to God Himself. This departure from Fichte was due to the pantheism of Spinoza, from whom Schelling derived the identification of God and Nature. But he passed Spinozism through the pure idealism of Fichte, and therefore regarded God, not as one substance partly extended and partly thinking, but as one intelligent subject; and Nature, not as God's extension, but with its extension and all its attributes as nothing but God's intelligence made manifest, beginning unconsciously in the inorganic world, and finally rising to conscious intelligence in man. Hence numerous phrases, such as, "Dead nature is only unripe intelligence," "Matter is slumbering spirit," "The process of Nature is an unconscious poetry," "Nature is the Odyssey of spirit," in which he strove to express his conversion of Spinoza's realistic into his own idealistic pantheism. Thus also the correspondence supposed by Spinoza between thought and extension, and the pre-established harmony supposed by Leibnitz between the perceptions of monads and the movements of bodies (phenomenal or substantial) were transformed into an identity of ideal and real, subjective and objective, in absolute reason. The hypothesis of parallelism became for the first time a hypothesis of identity. Again, Schelling's attention was soon diverted from Fichte to Kant; not, however, to the *Kritik*, but to the *Metaphysical Foundations of Natural Science*, wherein Kant had perversely tried to show that bodies are not impenetrable substances exerting repulsion and attraction, but are composed of these very forces. This work of Kant doubly affected Schelling: it suggested to him the idea of a *Naturphilosophie*, and of a construction of nature. But he passed Kantism, as well as Spinozism, through the pure idealism of Fichte. In the first place, he divided philosophy into two: (a) Transcendental philosophy proceeding from subject to object, (b) Natural philosophy proceeding from object to subject. He thus widened the method of philosophy by adding to Fichte's "transcendental" his own "natural" method. Secondly, he extended Fichte's process of construction from man's knowledge to Nature. According to him, not only knowledge, but also Nature, goes through the triple process of thesis, antithesis, and synthesis; Nature is the self-activity of the subject (*natura naturans*), which continually

becomes an object, and issues in a product (*natura naturata*) in which subject and object are identical; and this identity in duplicity is the foundation of repulsion and attraction, and repeats itself throughout the whole world, ideal and real. Hence, instead of speaking, with Fichte, of the Absolute Ego positing Nature as the non-Ego, Schelling prefers to say that Absolute Reason becomes Nature, the subject becomes the object, only to return into itself as a unity of opposites; so that nature as well as knowledge is a system of the rational, and everything is identified in the Absolute Reason. How then is this Absolute known? According to Schelling, by intellectual intuition. Kant had attributed to God, in distinction from man's understanding, an intellectual intuition of things. Fichte had attributed to man an intellectual intuition of himself as the Absolute Ego. Schelling attributes to man an intellectual intuition of the Absolute God; and as there is, according to him, but one universal reason, the common intelligence of God and man, this intellectual intuition at once gives man an immediate knowledge of God, and identifies man with God Himself.

On Schelling's idealistic pantheism, or the hypothesis that there is nothing but one absolute reason identifying the opposites of subjectivity and objectivity, Hegel based his panlogism. But, while he fully recognized his indebtedness to his master, he differed from him profoundly in one respect, which, being fundamental, could not but have many consequences. He rightly objected that the system was wanting in logical proof. He rightly, therefore, rejected the supposed intellectual intuition of the Absolute. He rightly contended that, if we are to know anything beyond sense, we must know it by a process of logical reason. But, unfortunately, he meant not the logical inferences described in the *Organon* and the *Novum Organum*, the analogical, inductive, and deductive processes, which enable us to infer other things similar to what we perceive in ourselves. He meant a new "speculative" method, dialectic, founded on an assumption which he had already learnt from Schelling, namely, that things which are different but similar can have the same attribute, and therefore be also the same. With this powerful instrument of dialectic in hand, he attempted to show how the Absolute gradually develops into the world and maintains itself; how being passes into its opposite, not-being, and returns into itself; how the Idea becomes Nature, and returns into itself in Spirit; how, in short, absolute reason differentiates itself into subjective and objective, ideal and real, and yet is the identity of both—an identity of opposites, as Schelling had said. By the same dialectic Hegel was able to justify the gradual transformation of transcendental into noumenal idealism by Fichte and Schelling. If things different but similar have the same attributes, and are thereby the same, then in the first place the Kantian categories, though thoughts of mental origin and therefore confined to mind, are nevertheless applicable to things, because things, though different from, are the same as, thoughts, and have the categories of thoughts; in the second place, the Fichtian Ego of mankind is not the Absolute Reason of God, and yet is the same Absolute Reason; in the third place, the Schellingian Nature is the "other" of Spirit, and yet, being a mere reflex of the Idea of Nature, is identical with Spirit; and as this Spirit is everywhere the same in God and men, Nature is also identical with our Spirit, or rather with the Infinite Spirit, or Absolute Reason, which alone exists. The crux of all metaphysical idealism is the difficulty of reconciling the unity of the object with the plurality of subjects. Hegel's assumption of identity in difference at once enabled him to deal with the whole difficulty by holding that different subjects are yet one subject, and

any one object, *e.g.*, the sun, is at once different from, and identical with, the one subject which is also many. By the rough magic of this modern Prospero, the universe of being is not, and yet is, thought, idea, spirit, reason, God. So elastic a solution established a dominant Hegelian school, which is now practically extinct, in Germany, and from Germany spread Hegelianism to France, England, America, and, in fact, diffused it over the civilized world to such an extent that it is still a widespread fashion outside Germany to believe that the world of being is a world of thought.

The plain answer is to contest the whole assumption. Different things, however similar, have only similar attributes, and therefore are never the same. God created man in His own image, and the world in the image of the Divine Idea; but I am not God, and the transitory sun is not the same as God's eternal idea of it. The creatures, however like, are not the same as the Creator and His thoughts. Each is a distinct thing, as Aristotle said. Reality is not Reason. It is strange that the underlying assumption of panlogism was not at once contested in this plain way. Nevertheless, objection was soon taken to the unsatisfactoriness of the system reared upon it. Schelling himself, as soon as he saw his own formulæ exposed in the logic or rather dialectic of his disciple, began to reconsider his philosophy of identity, and brought some powerful objections against both the conclusions and the method of Hegel. Schelling perceived that Hegel, in reducing everything to infinite mind, absorbed man's free but finite personality in God, and, in declaring that everything real is rational, failed to explain evil and sin: indeed, the English reader of T. H. Green's *Prolegomena to Ethics* can see how awkward is the Hegelian transition from "one spiritual principle" to different men's individual freedom of choice between good and evil. Again, Schelling urged that besides the rational element there must be something else; that there is in nature, as *natura naturans*, a blind impulse, a will without intelligence, which belongs to the existent; and that even God Himself as the Absolute cannot be pure thought, because in order to think He must have an existence which cannot be merely His thought of it, and therefore pure being is the prior condition of thought and spirit. Hence Schelling objected to the Hegelian dialectic on the ground that, although reason by itself can apprehend notions or essences, and even that of God, it cannot deduce *à priori* the existence either of God or of Nature, for the apprehension of which experience is required. He now distinguished two philosophies: negative philosophy starting from notions, and positive philosophy starting from being; the former a philosophy of conditions, the latter of causes, *i.e.*, of existence. Hegel, he said, had only supplied the logic of negative philosophy; and it must be confessed that the most which could be extracted from the Hegelian dialectic would be some connexion of thoughts without proving any existence of corresponding things. Schelling was right; but he had too much affinity with Hegelian assumptions, *e.g.*, the panlogistic confusion of the essences of things with the notions of reason, to construct a positive philosophy without falling into fresh mysticism, which failed to exorcise the effect of his earlier philosophy of identity in the growing materialism of the age.

(2) *Schopenhauer*.—Meanwhile, by the side of panlogism arose the panthelism of Schopenhauer (1788–1860). This new noumenal idealism began, like the preceding, by combining psychological idealism with the transcendentalism of Kant and Fichte. In *Die Welt als Wille und Vorstellung* Schopenhauer accepted Kant's position that the world as phenomenal is idea (*Vorstellung*); but he added that the world as noumenal is will (*Wille*). He

got the hint of a noumenal will from Kant; but in regarding the noumenal as knowable, because mental, as well as in the emphasis he laid on the activity of will, he resembled Fichte. His theory of the nature of will was his own, and arrived at from a voluntaristic psychology leading to a voluntaristic metaphysics of his own. His psychological starting-point was the unproved assumption that the only force of which we are immediately aware is will; his metaphysical goal was the consistent conclusion that in that case the only force we can know, as the noumenal essence of which all else is phenomenal appearance is will. But by this noumenal will he did not mean a divine will similar to our rational desire, a will in which an inference and desire of a desirable end and means produces our rational action. He meant an unintelligent, unconscious, restless, endless will. In considering the force of instinct in animals, where, without any apprehension of a prospective end, a present feeling of pleasure or pain, such as hunger, produces an impulsive action, he was obliged to divest will of reason. When he found himself confronted with the blind forces of Nature, where bodies insensibly change one another, he was obliged to divest irrational will of feeling. As he resolved one force after another into lower and lower grades of will, he was obliged to divest will of all consciousness. In short, his metaphysics was founded on a misnomer, and simply consisted in calling unconscious force by the name of unconscious will (*Unbewusster Wille*). This abuse of language brought him back to Leibnitz. But, whereas Leibnitz imputed unconscious perception as well as unconscious appetite to monads, Schopenhauer supposed unconscious will to arise without perception, without feeling, without ideas, and to be the cause of ideas only in us. Hence he rejected the infinite intelligence supposed by Fichte, Schelling, and Hegel, against whom he urged that blind will produces intelligence, and only becomes conscious in us by using intelligence as a means to ends. He also rejected the optimism of Leibnitz and Hegel, and placed the most irrational of wills at the base of the worst possible of worlds, holding that the state of will is a state of endless striving, a state of evil; that the will to live brings no happiness; that pain is positive evil and pleasure only its absence; that misery only increases with the accession of intelligence, and so the world becomes worse, until intelligence, by supplying will with a knowledge of its evil nature, enables it in the individual man to negate itself by virtue and asceticism, and so to be at peace. This pessimistic panthelism, though of little account during the Hegelian domination, gradually won its way, and procured exponents such as J. Franenstädt, J. Bahnsen, and, more recently, P. Deussen. The accident of its pessimism attracted F. W. Nietzsche, who afterwards, passing from the philosophy of will to the theory of evolution, ended by imagining that the struggle of the will to live produces the survival of the fittest, that is, the right of the strongest and the will to exercise power, which by means of selection may hereafter issue in a new species of superior man—the *Uebermensch*. Finally, Schopenhauer's voluntarism has had a profound effect on psychology inside and outside Germany, and to a less degree produced attempts to deduce from voluntaristic psychology new systems of voluntaristic metaphysics, such as those of Paulsen and Wundt.

(3) *E. von Hartmann*.—But the first to modify the pure voluntarism of Schopenhauer was E. von Hartmann, who, in *Die Philosophie des Unbewussten* (1869, 1st ed.), advanced the view that the world as noumenal is both unconscious intelligence and unconscious will, thus founding a panpneumatism which forms a sort of reconciliation of the panlogism of Hegel and the panthelism of Schopenhauer. In his tract entitled *Schelling's positive Philosophie*

als *Einheit von Hegel und Schopenhauer* (1869), he further showed that, in his later philosophy, Schelling had already combined reason and will in the Absolute. Indeed, Fichte had previously characterized the life of the Absolute by reason and will without consciousness; and, before Fichte, Leibnitz had asserted that the elements of Nature are monads with unconscious perception and appetite. Hartmann has an affinity with all these predecessors, and with Spinoza, with whom he agrees that there is but one substance unaltered by the plurality of individuals which are only its modifications. Following, however, in the footsteps of Schelling, he idealizes the one extended and thinking substance into one mental being; but he thinks that its essence consists in unconscious intelligence and will, of which all individual intelligent wills are only activities. The merit of this fresh noumenal idealism consists in its correction of the one-sidedness of Schopenhauer: intelligence is necessary to will. But Hartmann's criticism does not go far enough. Instead of concluding that will is intelligent desire to act by means to a future end, that instinct is feeling producing action, that unconscious force is stress of bodies mutually changing one another unconsciously, and that the conscious intelligent will of omnipresent God is the primary cause beneath all secondary causes, unconscious and conscious, he outdoes the paradox of Schopenhauer by concluding that Nature in itself is intelligent will, but unconscious, a sort of immanent unconscious God. As with his master, his reasons for this view are derived, not from a direct proof that unconscious Nature has the mental attributes supposed, but from human psychology and epistemology. Like Leibnitz, he proceeds from the fact that our perceptions are sometimes conscious, sometimes unconscious, to the inconsequent conclusion that there are beings with nothing but unconscious perceptions; and by a similar *non sequitur*, because there is the idea of an end in will, he argues that there must be an unconscious idea of an end in instinctive, in reflex, in all actions. Again, in his *Grundproblem der Erkenntnistheorie* (1889) he uses without proof the hypothesis of psychological idealism, that we perceive psychical effects, to infer with merely hypothetical consistency the conclusion of noumenal metaphysical idealism that all we can thereby know is psychical causes, or something transcendent, beyond phenomena indeed, yet not beyond mind. But, according to him, this transcendent is the unconscious, which is *Kraftvolles unbewusst ideales Geschehen*. He calls this epistemology "transcendent realism"; it is really "transcendent idealism." On these foundations he builds the details of his idealistic metaphysics. He identifies matter with mind by identifying atomic force with the striving of unconscious will after objects conceived by unconscious intelligence, and by defining causality as logical necessity receiving actuality through will. Secondly, he contends that, when matter ascends to the evolution of organic life, the unconscious has a power, over and above its atomic volitions, of introducing a new element, and that in consequence the facts of variation, selection, and inheritance, pointed out by Darwin, are merely means which the unconscious uses for its own ends in morphological development. Thirdly, he explains the rise of consciousness by supposing that, while it requires brain as a condition, it consists in the emancipation of intelligence from will at the moment when in sensation the individual mind finds itself with an idea without will. Here follows his pessimism, like to, but differing from, that of his master. In his view consciousness begins with want, and pain preponderates over pleasure in every individual life, with no hope for the future, while the final end is not consciousness, but the painlessness of the un-

conscious, which mankind will attain when, convinced of the misery of life, it will work a common resolve not to will, and somehow stop all will. But why exaggerate? The truth of Nature is force; the truth of will is rational desire; the truth of life is neither the optimism of Leibnitz and Hegel, nor the pessimism of Schopenhauer and Hartmann, but the moderatism of Aristotle. Life is sweet, and most men have more pleasures than pains in their lives.

(4) *Lotze and Zeller*.—Lotze (1817–1881) elaborated a very different noumenal idealism, which perhaps we may express by the name "Panteleologism," to express its conclusion that the known world beyond phenomena is neither absolute thought, nor unconscious will, nor the unconscious at all, but the activity of God; causing in us the system of phenomenal appearances, which we call Nature, or bodies moving in time and space; but being in itself the system of the universal reciprocal actions of God's infinite spirit, animated by the design of the supreme good. The *Metaphysik* of Lotze in its latest form (1879) begins with a great truth: psychology cannot be the foundation of metaphysics, metaphysics must be the foundation of psychology. He saw that the theories of the origin of knowledge in idealistic epistemology are unsound and lead to no solid result. Like Aristotle, then, he proposed anew the question, What is being? Nevertheless he was too much a child of his age to keep things known steadily before him, but had no sooner asked the metaphysical question than he proceeded to find a psychological answer in a theory of sensation, which asserted the mere hypothesis that the being which we ascribe to things on the evidence of sensation consists in their being felt. He really accepted, like Kant, the hypothesis of a sense of sensations which led to the Kantian conclusion that the Nature we know in time and space is mere sensible appearances in us. Further, from an early period in his *Medicinische Psychologie* (1852) he reinforced the transcendental idealism of Kant by a general hypothesis of "local signs," containing the subordinate hypotheses, that we cannot directly perceive extension either within ourselves or without; that spatial bodies outside could not cause in us spatial images either in sight or in touch; but that besides the obvious data of sense, e.g., pressure, heat, and colour, there must be other qualitative different excitations of different nerve-fibres, by means of which, as non-local signs of localities, the soul constructs in itself an image of extended space containing different places. This hypothesis of an acquired perception of a space mentally constructed by "local signs," brought forward in opposition to the nativistic hypothesis of Joh. Müller, supplied Lotze and many succeeding idealists, including Wundt, with a new argument for metaphysical idealism. Lotze concluded that we have no more reason for supposing an external space like space constructed out of our perceptions, than we have for supposing an external colour like perceived colour. Agreeing, then, with Kant that primary qualities are as mental as secondary, he agreed also with Kant that all the Nature we know as a system of bodies moving in time and space is sensible phenomena. But while he was in fundamental agreement with the first two positions of Kant, he differed from the third; he did not believe that the causes of sensible phenomena can be unknown things in themselves. What then are they? In answering this question Lotze regarded Leibnitz as his guide. He accepted the Leibnitzian fallacy that unity is indivisibility, which led to the Leibnitzian analysis of material bodies into immaterial monads, indivisible and therefore unextended, and to the theory of monadic souls and entelechies. Indeed, from the time of Leibnitz such attempts either to analyze or to construct matter had

become a fashion. Boscovich had supposed repulsive and attractive centres of force, and Kant had constructed matter with extension and impenetrability out of repulsion and attraction. Schelling had constructed all Nature out of the thesis, antithesis, and synthesis of spirit. Herbart had analysed it into "reals," or simple substances, each with an unknown quality. Lotze agreed with Leibnitz that the things which cause phenomena are immaterial elements, but added that they are not simple substances, self-acting, as Leibnitz thought, or preserving themselves against disturbance, as Herbart thought, but are interacting modifications of the one substance of God. In the first place, he resolved the doubt of Leibnitz about bodies by deciding entirely against his realistic alternative that an organic body is a *substantia realizans phenomena*, and for his idealistic alternative that every body is a phenomenon and not a substance at all. Secondly, he accepted the Leibnitzian hypothesis of immaterial elements without accepting their self-action. He believed in reciprocal action; and the very essence of his metaphysics consists in sublating the interaction of bodies into the interaction of immaterial elements, which produce effects on one another and on the soul as one of them. According to the mechanics of Newton, when two bodies collide and by their mutual resistance make one another move in opposite directions, each impresses on the other an equal change of momentum, so that as much momentum as one causes in one direction, the other causes in the opposite direction. Each body moving makes the other move equally and oppositely; but it has become a convenient habit to express this concrete fact in abstract language by calling it the conservation of momentum, by speaking as if not the equivalent but the very same momentum lost by one body is gained by the other, and by talking of one body communicating its motion to the other; as if bodies exchanged motion as men do money. Now Lotze took this abstract language literally, and had no difficulty in showing that, as an attribute is not separated from its substance, this supposed communication of motion does not really take place: nothing passes. But instead of returning to the concrete fact of the equivalence of momentum, by which each body moving makes the other move oppositely, he denied that bodies do reciprocally act on one another, and even that bodies as mutually resisting substances press one another apart in collision. Having thus rejected all bodily mechanism, he had to suppose that reciprocal action somehow takes place between immaterial elements. This brought him to another difference from Leibnitz as well as from Newton. According to Leibnitz, while each immaterial element is a monadic substance and self-acting secondary cause, God is the primary cause of all. According to Lotze, the connexion required by reciprocity requires also that the whole of every reciprocal action should take place within one substance; the immaterial elements act on one another merely as the modifications of that substance interacting within itself; and that one substance is God, who thus becomes not merely the primary but the sole cause, and in scholastic language is not a *causa transiens*, or creator of works beyond, but a *causa immanens*, or agent of acts remaining within, the agent's being. At this point, having rejected both the Newtonian mechanism of bodily substances and the Leibnitzian automatism of monadic substances, he flew to the Spinozistic unity of substance; except that, according to him, the one substance, God, is not extended at all, and is not merely thinking, but is a thinking, willing, and acting Spirit. Lotze's metaphysics is thus distinguished from the theism of Newton and Leibnitz by its pantheism, and from the pantheism of Spinoza by its idealism. It is an idealistic pantheism, which is a

denial of all bodily mechanism, a reduction of everything bodily to phenomena, and an assertion that all real action is the activity of God. At the same time it is a curious attempt to restore mechanism and reconcile it with teleology by using the word "mechanism" in a new meaning, according to which God performs His own reciprocal actions within Himself by uniform laws, which are also means to divine ends. It is also an attempt to reconcile this divine mechanism with freedom. In his *Metaphysik* (1879), as in his earlier *Mikrokosmos* (1856-64), Lotze vindicated the contingency of freedom by assigning to God a miraculous power of unconditional commencement, whereby not only at the very beginning but in the course of nature there may be new beginnings, which are not effects of previous causes, though once started they produce effects according to law. Thus his pantheistic is also a teleological idealism, which in its emphasis on free activity and moral order recalls Leibnitz and Fichte, but in its emphasis on the infinity of God has more affinity to Spinoza, Schelling, and Hegel. Indeed, it has been truly said by G. T. Ladd that Lotze tried to correct Hegel by substituting for a movement of absolute thought a movement of absolute life as the sum of reality. Hence his philosophy, like the Hegelian, continually torments one with the difficulty that its sacrifice of the distinct being of all individual substances to the universality of God entails the sacrifice of the individual personality of men. Our bodies were reduced by Lotze to the general ruck of phenomenal appearances. Our souls he tried his best to endow with a quasi-existence, arguing that the unity of consciousness requires an indivisible subject, which is distinct from the plurality of the body but interacting with it, is in a way a centre of independent activities, and is so far a substance, or rather able to produce the appearance of a substance. But at the end of his *Metaphysik*, from the conclusion that everything beyond phenomena is divine interaction, he drew the consistent corollary that individual souls are simply actions of the one genuine being. His final view was that certain actions of the divine substance are during consciousness gifted with knowledge of themselves as active centres, but during unconsciousness are non-existent. If so, we are not persons with a permanent being of our own distinct from that of God. But in a philosophy which reduces everything to phenomenal appearance except the self-interacting substance of God, there is no room for either the bodies or the souls of finite substances or human persons. Yet the pantheistic teleological idealism of Lotze has had, and still has, a wide influence in and out of Germany. The secret of this influence is the revival of the Leibnitzian analysis of matter into non-material elements. This influence appears in a most interesting way in Zeller's essay "Ueber die Gründe unseres Glaubens an die Realität der Aussenwelt," 1884 (in his *Vorträge*, iii. 225 seq.). After an able justification of our belief in the reality of the external world, Zeller contends that its forces are immaterial. He advances three arguments: the Leibnitzian argument that simple elements must be unextended, the Lotzian argument that the interactions of body and soul are explained by supposing them to belong to immaterial elements, and his own argument that, if the immaterial is common to the inner and outer worlds, we can at once maintain with Kant that space is *à priori*, and infer without fallacy that it also belongs to outer things in themselves made of immaterial elements. He remarks also that this reduction of the material to the immaterial is a point of agreement between Lotze and Fechner; but, while agreeing in other respects with Lotze, he adds, "I do not hold space, as he does, to be something merely belonging

to our apprehension." In short, his view is that there is an inner and an outer spatial world, composed of immaterial elements, whose forces produce in us the appearance of impenetrable bodies. In a similar way, W. Ostwald, taking advantage of the abstraction of energy from bodies having the power of doing work on one another, concludes that energy is immaterial, and nature consists of immaterial energy. He neglects the facts, that the mass included in energy is known to us only as mass of body, that all we know about any energy has been discovered from bodies, and that all the elements of bodies known to us are more elementary bodies. This last is the fact neglected in the analysis of the material into the immaterial from Leibnitz to the present day. The original cause of error was the Pythagorean fancy that the "one" is the origin of all things. But everything known to us is, as Aristotle said, an individual substance, one as undivided not as indivisible; and some substances are bodies. We attend for simplicity to the undividedness of a body, or to its position, or to a central position in it, or to its power of doing work; but we have no evidence that a monad, or a point, or a centre of force, or an energy, has any reality distinct from a body.

(5) *Fechner and Paulsen*.—Fechner (1801–1887) affords a conspicuous instance of the idealistic tendency to mysticize nature in his Panpsychism, or that form of noumenal idealism which holds that the universe is a vast communion of spirits, souls of men, of animals, of plants, of earth and other planets, of the sun, all embraced as different members in the soul of the world, the highest spirit—God, in whom we live and move and have our being; that the bodily and the spiritual, or the physical and the psychical, are everywhere parallel processes which never meet to interact; but that the difference between them is only a difference between the outer and inner aspects of one identical psychophysical process; and yet that both sides are not equally real, because, while psychical and physical are identical, the psychical is what a thing really is as seen from within, the physical is what it appears to be to a spectator outside; or spirit is the self-appearance of matter, matter the appearance of one spirit to another. Fechner's panpsychism has a certain affinity both to Stahl's animism and to the hylozoism of materialists such as Haeckel. But, while it differs from both in denying the reality of body, it differs from the former in extending conscious soul not only to plants, as Stahl did, but to all nature; and it differs from the latter in the different consequences drawn by materialism and idealism from this universal animism. According to Haeckel, matter is the universal substance, spirit its universal attribute. According to Fechner, spirit is the universal reality, matter the universal appearance of spirit to spirit; and they are identical because spirit is the reality which appears. Hence Fechner describes himself as a twig fallen from Schelling's stem. The religious feeling inspired by his clerical parentage and his pursuit of natural science, of which he was at first a professor, inclined him to the theosophical author of the *Naturphilosophie*. It was Schelling's adherent Oken who by his *Lehrbuch der Naturphilosophie* conveyed to his mind the life-long impression that God is the universe and nature God's appearance. At the same time, while accepting the Schellingian parallelistic identity of all things in God, Fechner was restrained by his accurate knowledge of physics from the extravagant construction of Nature, which had failed in the hands of Schelling and Hegel. Besides, he was deeply impressed by the fact of man's personality and by the problem of his personal immortality, which brought him back through Schelling to Leibnitz, whose *Monadologie* throughout maintains the plurality of monadic souls and the om-

nipresence of perception, sketches in a few sections (§§ 23, 78–81) a panpsychic parallelism, though without identity, between bodily motions and psychic perceptions, and, what is most remarkable, already uses the conservation of energy to argue that physical energy pursues its course in bodies without interacting with souls, and that motions produce motions, perceptions produce perceptions. Leibnitz thus influenced Fechner, as in other ways he influenced Lotze. Both, however, used this influence freely; and, whereas Lotze used the Leibnitzian argument from indivisibility to deduce indivisible elements and souls, Fechner used the Leibnitzian hypotheses of universal perception and parallelism of motions and perceptions, in the light of the Schellingian identification of physical and psychical, to evolve a world-view (*Weltansicht*) containing something which was neither Leibnitz nor Schelling. Fechner's first point was his panpsychism. Emphasizing the many real analogies between physical and mental agency, but underrating the much stronger evidences that all the mental operations of men and animals require a nervous system, he flew to the paradox that soul is not limited to men and animals, but extends to plants, to the earth and other planets, to the sun, to the world itself, of which, according to him, God is the world-soul. In this doctrine of universal animation he was like Leibnitz, yet very different. Whereas Leibnitz confined a large area of the world to wholly unconscious perceptions, and therefore preferred to call the souls of inorganic beings "Entelechies," Fechner extended consciousness to the whole world; and accordingly, whereas Leibnitz believed in a supremundane Creator, "au dessus du Monde" and "dans le Monde," Fechner, in the spirit of Schelling, identified God with the soul of the world. Fechner's second point was that, throughout the animated universe, physical processes accompany psychical processes without interaction. In this panpsychistic parallelism he was again like Leibnitz, and he developed his predecessor's view, that the conservation of energy prevents interaction, into the supposition that alongside the physical there is a parallel psychical conservation of energy. Here, again, he went much further than Leibnitz, but along with Schelling, in identifying the physical and the psychical as outer and inner sides of the same process, in which the inner is the real and the outer the apparent. Fechner's third point carried him beyond all his predecessors, containing as it does the true originality of his "world-view." He advanced the ingenious suggestion that, as body is in body and all ultimately in the world-body, so soul is in soul and all ultimately in the world-soul. By this means he explained immortality by supposing that in this life every man, according to his works, fashions himself a higher body which is as much of the common body of the earth as he has developed in this life, and that death is only the continuation of the life of the soul with higher powers in this higher body of the earth, and, if the earth fell into the sun, then in the still higher body of the sun; while the soul throughout is interwoven with other spirits in the highest spirit of the world, or God. By the same means he vindicated our personality, on the ground that each spirit is a different member of the same great spirit, and that in a future state the new body is a continuation of the old body, and the new soul of the old soul, by an eternal conservation of the energy of both. Fechner's fourth point was connected with this inclusion of personal spirits in higher spirits and in the highest. It is his so-called "synechological view" of the soul. Herbart and Lotze, both deeply affected by the Leibnitzian hypothesis of indivisible monads, supposed that man's soul is seated at a central point in the brain; and Lotze supposed that this supposition is necessary to explain the unity of

consciousness. Fechner's supposition was that the unity of consciousness belongs to the unity of the whole body; that the seat of the soul is the living body; that the soul changes its place as in different parts a process rises above the "threshold of consciousness"; and that soul is not substance but the single psychical life which has its physical manifestation in the single bodily life. Applying this "synechological view" to the supposed inclusion of soul in soul, he deduced the conclusion that, as here the nature of one's soul is to unite one's little body, so hereafter its essence will be to unite a greater body, while God's spirit unites the whole world by His omnipresence; and he pertinently asked, in opposition to the "punctual" view, whether God's soul is centred in a point. Lastly, the whole of this "world-view" was developed by Fechner in early life, under the influence of his religious training, and out of a pious desire to understand those main truths of Christianity which teach us that we are children of God, that this natural body will become a spiritual body, and that, though we are different individual members, we live and move and are in God: "in Deo vivimus, movemus, et sumus." It is important to notice that Fechner maintained this "world-view" in a little book, *Das Büchlein vom Leben nach dem Tode*, which he originally published in 1836 under the pseudonym of Dr Mises, but which he afterwards republished in his own name in 1866, and again in 1887, as a sketch of his *Weltansicht*. Afterwards in *Nanna* (1848) he discussed the supposed souls of plants, and in *Zendavesta* (1851) the supposed souls of the earth and the rest of the world. Then in 1855 he published his *Atomlehre*, partly founded on his physics, but mainly on his metaphysics. Under the influence of Leibnitz, Boscovich, Kant, and Herbart, he supposed that bodies are divisible into punctual atoms, which are not bodies, but centres of forces of attraction and repulsion; that impenetrability is a result of repulsive force; and that force itself is only law—taking as an instance that Newtonian force of attraction whose process we do not understand, and neglecting that Newtonian force of pressure and impact whose process we do understand from the collision of bodies already extended and resisting. But, in thus adapting to his own purposes the Leibnitian analysis of material into immaterial, he drew his own conclusions according to his own metaphysics, which required that the supposed centres of force are not Leibnitzian "monads," nor Herbartian "reals," nor divine modifications such as Lotze afterwards supposed, but are elements of a system which in outer aspect is bodily and in inner aspect is spiritual, and obeying laws of spirit. At the same time, his synechological view prevented him from saying that every atom has a soul, because according to him a soul always corresponds to a unity of a physical manifold. Thus his metaphysics is Leibnitzian like that of Lotze, and yet is opposed to the most characteristic feature of monadology—the percipient indivisible monad.

In 1860 appeared Fechner's *Elemente der Psychophysik*, a work which has deeply affected recent psychology, and almost revolutionized recent metaphysics of body and soul, and of physical and psychical relations generally. It becomes necessary, therefore, to determine how far Fechner derived his psychophysics from experience, how far from fallacies of inference, from his romantic imagination and from his theosophic metaphysics, which indeed coloured his whole book on psychophysics. At the very outset he started with his previous metaphysical hypothesis of parallelistic identity without interaction. He now compared the spiritual and bodily sides of a man to the concave and convex sides of a circle, as inner and outer sides of the same process, which is psychical as viewed from within and physical as viewed from without.

He also maintained throughout the book that physical and psychical energy do not interfere, but that the psychical is, like a mathematical quantity, a function of the physical, depending upon it, and *vice versa*, only in the sense that a constant relation according to law exists, such that we may conclude from one to the other, but without one ever being cause of the other. By his psychophysics he meant the exact doctrine of the relations of dependency between physical and psychical. The name was new, but not the doctrine. From antiquity men had applied themselves to determine the relations between the physical stimuli and the so-called "quality" of sensations; and especially in acoustics the Pythagoreans showed that the lengths of strings, and the moderns that the vibrations of air, vary in a geometrical ratio as the height of audible sounds varies in an arithmetical progression, or that musical intervals are proportional to the logarithms of the ratios of the vibrations, or of the lengths of vibrating strings. But what was new in the 19th century was the application of this doctrine to the relations between the stimuli and the so-called "intensity" of sensations. By experiments on touch in 1849 E. H. Weber showed that in lifting weights the increase in weight of stimulus necessary to produce a sensible difference of intensity between two tactile sensations is not a constant quantity, but varies with the previous stimulus so as to be always a constant fraction of the previous stimulus. Thus, if an increase from 40 to 41 grammes produced a sensible difference, it required an increase from 80 to 82, from 400 to 410, from 800 to 820, to produce these higher sensible differences; or always $\frac{1}{40}$ of the previous stimulus. Thereupon Fechner, incited by a hypothesis which occurred to him in 1850, discovered by a great number of experiments, conducted in most methodical ways, that Weber's law, as he called it after the name of his master, admits of being generalized to all the senses, but that the constant function of the previous stimulus is different for different senses: in sound $\frac{1}{3}$, in light only $\frac{1}{100}$, and so forth. Hence he generalized Weber's law in the form that sensation generally increases in intensity as the stimulus increases by a constant function of the previous stimulus; or increases in an arithmetical progression as the stimulus increases in a geometrical ratio; or increases by addition of the same amount as the stimulus increases by the same multiple; or increases as the logarithm of the stimulus. This law of the measure of sense Fechner called the *Massformel*; and as Herbart had called the least stimulus necessary to conscious sensation the "threshold," so Fechner called the least difference of stimulus necessary to conscious difference of sensation the "difference-threshold," which, according to the law, is always a constant fraction of the previous stimulus for any one sense. There are then, at least within the limits of moderate sensations, concomitant variations between stimuli and sensations, not only in "quality," as in the intervals of sounds, which were understood long ago, but also in "intensity"; and the discovery of the latter is the importance of Weber's and Fechner's law. By the rules of induction from concomitant variations, we are logically bound to infer the realistic conclusion that outer physical stimuli cause inner sensations of sensible effects. But, unfortunately for Fechner, the very opposite conclusion followed from the presuppositions of his parallelistic metaphysics, and from the Leibnitzian view of the conservation of energy, which he was the first in our time to use in order to argue that a physical cause cannot produce a psychical effect, on the ground that physical energy must be exactly replaced by physical energy.

It is certain that a body does work in the mechanical sense on body, and thereby always causes therein changes

of motion and configuration or relative position; and it is very probable that, so far as its energy or working power is diminished by its being resisted, it always causes an increase of energy, so that the amount of energy before and after in the whole system is equivalent, so long as we count, besides molar, molecular energy of sound, heat, &c., and both kinetic energy, or power of doing work in virtue of actual motion (*e.g.*, in a body being raised), and potential energy, or power of doing work in virtue of configuration with potential motion (*e.g.*, in a body having been raised to a position from which it can fall). But, as Clerk Maxwell remarked, we do not know that all changes are in configuration and motion, or that all energy must be either potential or kinetic. Hence we cannot say that a body does nothing but work in the mechanical sense, or causes no other changes but those in motion and configuration, even in body. Still less can we say that a body causes no other changes in soul, which, not being a resisting substance, would not diminish the energy of a body acting upon it, and therefore would in any case be affected by a body only in a non-mechanical way. It is true that from the conservation, or rather equivalence, of energy, whenever a body does work, we can deduce that probably a change produced, *e.g.*, heat, though not apparently, is really a change either in motion or in configuration; but this evidence becomes less certain in proportion to our ignorance of the changes in question, and in any case does not prove that there are no other changes produced. Now, changes in a nervous organism are conspicuous instances of this uncertainty. What is a nervous process, and how far is it a change in motion and configuration? What is a sensation? Is it a nervous process or not, or partly so and partly not? (*cf.* Case, *Physical Realism*, chap. v.). In our uncertainty about the nature of these changes it is open to us to believe in the conservation of energy and yet recognize its limits. A stimulus, exerting as it always does some pressure on the nerves, and causing an internal pressure which we feel by touch, does work on the nerves; it therefore causes changes in motion and configuration, molar and molecular, in them, though these are very imperfectly understood; and, so far as its own energy is thereby diminished, it probably causes in them an equivalent increase of energy, potential or kinetic, though this sum has not been calculated. But it is quite consistent to contend that the stimulus, at the same time that it causes a nervous change in motion and configuration by work, also causes a sensation which is a different kind of change; that thereupon these mechanical and non-mechanical changes cause further mechanical changes in the brain together with the non-mechanical change of thinking, and these again still further mechanical changes together with non-mechanical volition; and that finally these mechanical and non-mechanical changes produce changes in the motor nerves, and so forth, without any breach of nervous continuity, and without disturbing the equivalence of mechanical energy, and yet so that the non-mechanical changes of body and soul co-operating complicate the result. This contention, no doubt, if it were drawn from mere consistency, would not infer truth. But we have other evidences of its truth; first, from consciousness itself, which assures us that operations with which it interferes, as in writing a book, far outstrip unconscious operations in complexity, by which is not meant mere mechanical energy, of effect; and, secondly, from experiment, the very experiments completed by Fechner himself, which make us practically certain that stimulus and sensation vary so concomitantly that the former produces the latter. We are more certain of this induction from concomitant variations than of any deduction from conservation of energy to organic change. Yet Fechner

refused to draw the only logical conclusion from his own evidence, and in spite of it supposed that physical stimulus only causes physical nervous process, and not sensation. Why? Partly because he did not understand the limits of the conservation of energy, and partly because of his preconceived metaphysics, which had long condemned him to the fallacy of physical and psychical parallelism without mutual interference.

Having thus satisfied himself in what he called "outer psychophysics" that the stimulus causes only the nervous process and not sensation, he passed to what he called "inner psychophysics," or the theory of the relation between nervous and psychical processes. He rightly argued against the old theory that the continuity of nervous processes in the brain is interrupted by mental processes of thought and will: there is a nervous process for every mental process. But two questions then arose. What is the relation between nervous process and sensation? What causes sensation? The first question he answered from his imagination by supposing that, while the external world is stimulus of the nervous process, the nervous process is the immediate stimulus of the sensation, and that the sensation increases by a constant fraction of the previous stimulus in the nervous system, when Weber's law only proves that it increases by a constant fraction of the previous stimulus in the external world. The second question he answered from his parallelistic metaphysics by deducing that even within the organism there is only a constant dependency of sensation on nervous process without causation, because the nervous process is physical but the sensation psychical. This answer supposed that the whole physical process from the action of the external stimulus on the nervous system to the reaction of the organism on the external world is one series, while the conscious process beginning with sensation is only parallel and as it were left high and dry. What then is the cause of the sensation? Huxley, it will be remembered, in similar circumstances, answered this question by degrading consciousness to an epiphenomenon, or bye-product of the physical process. Fechner was saved from this absurdity, but only to fall into the greater absurdity of his own panpsychism. Having long assumed that the whole world is animated throughout, and that there are always two parallel series, physical and psychical, he concluded that, while a physical stimulus is causing a physical nervous process, a psychical accompaniment of the stimulus is causing the sensation, which, according to him, is the psychical accompaniment of the nervous process; and that, as the whole physical and the whole psychical series are the same, differing only as outer and inner, this identity holds both of stimulus and its psychical accompaniment and of nervous process and its accompanying sensation. Accordingly, he calls these and all other processes "psychophysical"; and as he recognized two parallel energies, physical and psychical, differing only as outer and inner aspects of the same energy, he called this "psychophysical energy." In such a philosophy all reality is "psychophysical." At the same time Fechner would not have us suppose that the two sides are equal; according to him, the psychical, being the psychophysical viewed from within, is real, the physical, being the psychophysical as viewed from without, is apparent; so in oneself, though nervous process and psychical process are the same, it is the psychical which is the reality of which the nervous is mere appearance; and so everywhere, spirit is the reality, body the appearance of spirit to spirit. Finally, he supposed that one spirit is in another, and all in the highest spirit, God. By this means also he explained unconsciousness. In point of fact, many stimuli are beneath the "threshold" of a

man's consciousness. Leibnitz, in the *Nouveaux Essais*, ii. 11, had also said that we have many "petites perceptions," of which we are unconscious, and had further suggested that a perception of which we are, is composed of a quantity of "petites perceptions" of which we are not, conscious. Proceeding on this suggestion, and misled by the mathematical expression which he had given to Weber's law, Fechner held that a conscious sensation, like its stimulus, consists of units, or elements, by summation and increments of which conscious sensations and their differences are produced; so that consciousness, according to this unnecessary assumption, emerges from an integration of unconscious shocks or tremors. But by the hypothesis of the inclusion of spirit in spirit, he was further able to hold that what is unconscious in one spirit is conscious in a higher spirit, while everything whatever is in the consciousness of the highest spirit of God, who is the whole of reality of which the spirits are parts, while the so-called physical world is merely outer appearance of one spirit to another.

Fechner first confused physics and metaphysics in psychophysics, and next proceeded to confuse them again in his work on evolution (*Einige Ideen zur Schöpfungs- und Entwicklungs-geschichte der Organismen*, 1873). He perceived that Darwinism attributed too much to accident, and was also powerless to explain the origin of life and of consciousness. But his substitute was his own hypothesis of panpsychism, from which he deduced a "cosmorganic" evolution from a "cosmorganic" or original condition of the world as a living organism into the inorganic, by the principle of tendency to stability. The world, as he thought, on its physical side, always was a living body; and on its psychical side God always was its conscious spirit; and, so far from life arising from the lifeless, and consciousness from unconsciousness, the life and consciousness of the whole world are the origin of the lifeless and the unconscious in parts of it, by a kind of secondary automatism, while we ourselves are developed from our own mother-earth by differentiation. By thus supposing a psychical basis to evolution, Fechner, anticipating Wundt, substituted a psychical development of organs for Darwinian accidental variation. Where Darwin would say that a cock has crest and spurs because individuals happened to vary in this advantageous manner, Fechner would suppose, as the inner aspect of the physical organism, a "psychical impulse" (*psychische Streben*) to fight, predisposing the germs and therewith the offspring. The difficulty of such speculations is to prove that things apparently dead and mindless are living souls. Their interest to the metaphysician is their opposition to physics on the one hand and to theism on the other. We have nowadays to ask ourselves whether we are to resign our traditional belief that the greater part of the world is mere body, but that its general adaptability to conscious organisms proves its creation and government by God, and to take to the new hypothesis, which, by a transfer of design from God to Nature, supposes that everything physical is alive, and conducts its life by psychical impulses of its own. Fechner himself went even farther, and together with design transferred God Himself to Nature. This is the subject of his last metaphysical work, *Die Tagesansicht gegenüber der Nachtansicht* (1879). The "day-view" is the view that God is the psychophysical all-embracing being, the law and consciousness of the world; as opposed to the "night-view," according to which the world is not throughout psychical, but consciousness appears only transiently in men and animals, while the rest of the world is dark night. The "day-view," which is Fechner's, resembles the views of Hegel and Lotze in its pantheistic tendency. But it does not, like theirs, sacrifice

our personality; because, according to Fechner, there is neither one infinite mind with which our mind is identical, nor one infinite active substance of which we are modifications, but one divine consciousness, which includes us as a larger circle includes smaller circles. By this ingenious suggestion of the membership of one spirit in another, Fechner's "day-view" also puts Nature in a different position; neither with Hegel sublimating it to the thought of God's mind, nor with Lotze degrading it to the phenomena of our human minds, but identifying it with the outer appearance of one spirit to another spirit in the highest of spirits.

We have dwelt on this curious metaphysics of Fechner because it contains the master-key to the philosophy of the present moment. While he was developing it during the domination of Hegelianism, and the subsequent reaction to materialism, it attracted little notice. But when the later reaction to Kant arose against both Hegelianism and materialism, the nearly contemporary appearance of Fechner's *Psychophysics* began to attract experimental psychologists by its real as well as its apparent exactness, and both psychologists and metaphysicians by its novel way of putting the relations between the physical and the psychical in man and in the world. Fechner enjoyed the felicity of seeing psychology deriving advantage from the methods, as well as the results, of his experiments, and of seeing in 1879 the first psychological laboratory erected by Wundt in his own Leipzig. But he had also to endure countless objections to his mathematical statement of Weber's law, to his unnecessary assumption of units of sensation, and to his unjustifiable transfer of the law from physical to physiological stimuli of sensations, involving in his opinion his parallelistic view of body and mind. Among psychologists Helmholtz, Mach, Brentano, Hering, Delboëuf were all more or less against him. Sigwart in his *Logic* has also opposed the parallelistic view itself; and James has criticized it from the point of view that the soul selects out of the possibilities of the brain means to its own ends. Nevertheless, largely under the influence of the exaggeration of the conservation of energy, many psychologists—Wundt, Paulsen, Riehl, Jodl, Ebbinghaus, Münsterberg, and in England Lewes, Clifford, Romanes, Stout—have accepted Fechner's Leibnitzian hypothesis of non-interacting parallelism between stimuli and sensations, nervous-processes and sensations, body and soul; as far at least as men and animals are concerned. Most stop here, preferring with Wundt to content themselves with this psychological parallelism. But some go with Fechner to the full length of his metaphysical parallelism of the physical and psychical, as psychophysical, throughout the whole world; and this influence has extended from Germany to Denmark, where it has been embraced by Höffding, and to England, where it has been accepted by Romanes, and in a more qualified manner as "a working hypothesis" by Stout. But the most thorough and most eloquent of Fechner's metaphysical disciples is F. Paulsen, who has spread panpsychism far and wide in his well-known *Einführung in die Philosophie*, published in 1892, and republished at least seven times since. Here reappear all the characteristic points of Fechner's "world-view"—the panpsychism, the universal parallelism with the identification of physical and psychical, the inclusion of spirit in spirit, the synechological view of spirit, and the final "day-view" that all reality is spirit, and body the appearance of spirit to spirit. But this is not all: Paulsen tries to supply something wanting in Fechner. Fechner was a psychophysical metaphysician, and a metaphysical psychologist, but he troubled himself little about epistemology, and the question—How do we know all these psychophysical things? He thought little of Kant's criticism,

which ended in admitting without explaining things in themselves. Now, the originality of Paulsen consists in trying to supply an epistemological explanation of the metaphysics of Fechner, by reconciling him with Kant and Schopenhauer. He borrows from Kant's "rationalism" the hypothesis of a spontaneous activity of the subject with the deduction that knowledge begins from sense, but arises from understanding; and he accepts from Kant's metaphysical idealism the consequence that everything we perceive, experience, and know about physical nature, and the bodies of which it consists, is phenomena, and not bodily things in themselves. But he has a different theory of human nature and soul, and so does not accept the Kantian conclusion that things in themselves, in the sense of things beyond phenomena, are all unknowable. On the contrary, his contention is that of Fechner—that all knowable things are inner psychological realities beneath outer physical appearances—the invisible symbolized by the visible. Kant, however, had no epistemology for such a contention, because according to him both outer and inner senses give mere appearance, from which we could not know either body in itself, or soul in itself. Parting, then, from Kant, Paulsen resorts to a paradox which he shares with Fechner and Wundt. He admits, indeed, Kant's hypothesis that by inner sense we are conscious only of mental states, but he contends that this very consciousness is a knowledge of a thing in itself. He agrees with Fechner and Wundt that there is no substantial soul, and that soul is nothing but the mental states, or rather their unity—thus identifying it with Kant's synthetic unity. On this assumption he deduces that in being conscious of our mental states we are conscious of soul not merely as it appears, but as it is in itself, and therefore can infer similar souls, other psychological unities, which are also things in themselves. But what is the essence of this psychological reality which we thus immediately and mediately know? For an answer to this question he appeals from Fechner to Schopenhauer, believing that, while Fechner excels Schopenhauer in his clear insight that the inner world is no explanation of the physical world, Schopenhauer on his side has the advantage of a voluntaristic psychology. Hence he is one of the now numerous band who tell us, after Schopenhauer, that will of some sort is the fundamental fact of mental life. Taking, then, will to be the essential thing in itself of which we are conscious, he deduces that we can infer that the psychological things in themselves beyond ourselves are also essentially "wills." Then combining the central dogma of Fechner that spirit extends throughout the world of bodily appearance, and the central dogma of Schopenhauer that what in idea appears to us as body is in itself "will," he concludes that the realities of the world are "wills," that bodies are mere appearances of "wills," and that there is one universal and all-embracing spirit, which is "will." His ultimate metaphysics, then, is this:—Everything is spirit, and spirit is "will." Lastly, he interprets "will" according to his premisses. By "will" he does not mean "rational desire," which is its proper meaning, but inapplicable to Nature; nor unconscious irrational will, which is Schopenhauer's forced meaning; nor unconscious intelligent will, which is Hartmann's more correct meaning, though inapplicable to Nature. What he does mean by "will" is instinct, impulsive feeling, a "will to live," not indeed unconscious, but often subconscious, without idea, without reasoning about ends and means, yet pursuing ends—in short, what he calls, after K. E. von Baer, *Zielstrebigkeit*. In this sense of appetite he makes out everything, which appears as a body, to be really in inner essence a "will." How persistent is ancient animism! Empedocles, Plato, and Aristotle;

Telesio, Bruno, and Campanella; Leibnitz; the idealists, Schopenhauer and Hartmann, Fechner and Paulsen; and the materialist, Haeckel—all have agreed in according some sort of appetite to Nature. So prone are men to exaggerate adaptation into aim! So prone are they to transfer to Nature the part played by the providence of God! (see Bacon, *De Augmentis*, iii. 4, *sub fin.*).

It would be a mistake to suppose that noumenal idealism is dead in Germany. It died down for a time in the decline of Hegelianism and the rise of materialism. It has since revived. The pure idealism of Fichte is at the bottom of it all. The panlogism of Schelling and Hegel survives in its influence. So still more does the pantheism of Schopenhauer. The three most vital idealisms of the kind at the moment are the panpneumatism of Hartmann, combining Hegel with Schopenhauer; the panteleologism of Lotze, reviving Leibnitz; and the pansychism of Paulsen, continuing Fechner, but with the addition of an epistemology combining Kant with Schopenhauer. All these systems of metaphysics, differ as they may, agree that things are known to exist beyond sensible phenomena, but yet are mental realities of some kind. Meanwhile, the natural substances of Aristotelian realism are regarded with common aversion.

§ 5. PHENOMENAL IDEALISM IN GERMANY.

Phenomenal idealism is the metaphysics which deduces that, as we begin by perceiving nothing but mental phenomena of sense, so all we know at last from these data is also phenomena of sense, actual or possible. So far it is in general agreement not only with Hume, but also with Kant in his first two positions. But it follows Fichte in his revolt against the unknown thing in itself. On the other hand, as the speculative systems of noumenal idealism, starting from Fichte, succeeded one another, like ghosts who "come like shadows, so depart," without producing conviction, and often in flagrant opposition to the truths of natural science, and when, in consequence, a wave of materialism threatened to submerge mind altogether by reducing it to a function of matter, many philosophers began to despair of the ambitious attempts which had been made to prove that there is a whole world of mind beyond phenomena, as the noumenalists had supposed. Thus they were thrown back on the limits of human knowledge prescribed by Kant, but purged of the unknown thing in itself by Fichte. They contented themselves with the result that the world we know is phenomenal, a world of experience (*Erfahrungswelt*), with no power of reason to infer things beyond phenomena of sense, actual and possible; and they endeavoured to show that this world of phenomena provides a sufficient field for natural science, a sufficient vindication of mind against materialism, a sufficient justification of idealism. Phenomenal idealism, in short, is the Kantian contention that Nature, as known to science, is phenomena of experience. Unfortunately, the word "phenomenon" is equivocal (see *Mind*, xiv. 309). Sometimes it is used for any positive fact, as distinguished from its cause; in this sense everything is a phenomenon, and indeed in this sense Aristotle spoke of God's intelligence as the divinest of phenomena. But sometimes also it means what appears, or can appear, to the senses, as distinguished from what does not appear, but can be inferred to exist. Now, Kant and his followers start from this second and narrower meaning, and usually narrow it still more by assuming that what appears to the senses is as mental as the sensation, being undistinguishable from it or from the idea of it, and that an appearance is a mental idea (*Vorstellung*) of sense; and then they conclude that we can know by influence nothing but such mental appearances, actual and possible, and therefore nothing beyond sensory

experience. When, on the other hand, the objects of science are properly described as phenomena, what is meant is not this pittance of sensible appearances, but positive facts of all kinds, whether perceptible or imperceptible, whether capable of being experienced or of being inferred from, but beyond, experience, *e.g.*, the farther side of the moon which, as the moon only rotates once in a revolution, is always turned away from a spectator on the earth, from his senses, from his experience, actual or possible, and yet is known to exist by inference. Hence the doctrine of Kant, that Nature as known to science is phenomena, means one thing in Kantism and another thing in science. In the former it means that Nature is mental phenomena, actual and possible, of sensory experience; in the latter it means that Nature is positive facts, either experienced or inferred. It is most important also to notice that Kantism denies, but science asserts, the logical power of reason to infer actual things beyond experience. But the phenomenal idealists have not, any more than Kant, noticed the ambiguity of the term "phenomenon"; they fancy that, in saying that all we know is phenomena in the Kantian sense of mental appearances, they are describing all the positive facts that science knows; and they follow Kant in supposing that there is no logical inference of actual things beyond experience.

(1) *The Reaction to Kant.*—The reaction to Kant ("Zurück zu Kant!") was begun by O. Liebmann in *Kant und die Epigonen* (1865), and expressed in his often-quoted words, "Es muss auf Kant zurückgegangen werden." Immediately afterwards, in 1866, appeared Lange's *Geschichte des Materialismus*. In 1870 J. B. Meyer published his *Kant's Psychologie*, and in 1871 H. Cohen his more important *Kant's Theorie der Erfahrung*, which led Lange to modify his interpretation of Kant in the second edition of his own book. Lange (1828-1875) by his *History of Materialism* has exercised a profound influence, which is due partly to its apparent success in answering materialism by Kantian arguments, and partly to its ingenious attempt to give to Kantism itself a consistency, which, however, has only succeeded in producing a new philosophy of Neo-Kantism, differing from Kantism in modifying the *à priori* and rejecting the thing in itself. Lange to some extent modified the transcendentalism of Kant's theory of the origin of knowledge. *À priori* forms, according to Kant, are contributions of the mental powers of sense, understanding, and reason; but, according to Lange, they are rooted in "the physico-psychical organization." This modification was the beginning of a gradual lessening of the antithesis of *à priori* to *à posteriori*, until at last the *à priori* forms of Kant have been transmuted into "auxiliary conceptions," or "postulates of experience." But this modification made no difference to the Kantian and Neo-Kantian deduction from the epistemological to the metaphysical. Lange entirely agreed with Kant that *à priori* forms can have no validity beyond experience when he says, "Kant is at any rate so far justified as the principle of intuition in space and time *à priori* is in us, and it was a service to all time that he should, in this first great example, show that what we possess *à priori*, just because it arises out of the disposition of our mind, beyond our experience has no longer any claim to validity" (*Hist. of Materialism*, translated by E. C. Thomas, ii. 203). Hence he deduced that whatever we know from sensations arranged in such *à priori* forms are objects of our own experience and mental phenomena. Hence also his answer to materialism. Science, says the materialist, proves that all known things are material phenomena. Yes, rejoins Lange, but Kant has proved that material are merely mental phenomena; so that the more the materialist proves his case the more surely he is playing into the

hands of the idealist—an answer which would be complete if it did not turn on the equivocation of the word "phenomenon," which in science means any positive fact, and not a mere appearance, much less a mental appearance, to sense and sensory experience. Having, however, made a deduction, which is at all events consistent, that on Kantian assumptions all we know is mental phenomena, Lange proceeded to reduce the rest of Kantism to consistency. He saw that if all logical inference is limited to mental phenomena of experience, we can form ideas of things beyond, but not know corresponding realities. Consequently he retracted Kant's admission that the thing in itself is something existing though unknowable. He regarded the thing in itself as a mere idea of limit, a limitative idea, an ideal, which we must conceive as a necessary outcome of our organization—but that is all; and when Cohen, taking advantage of some passages in which Kant speaks of the thing in itself as the idea of phenomena under the conception of an object in general, had, like Fichte before him, contended that this was all Kant had really meant, Lange, in his second edition, adopted this interpretation, and contended that the thing in itself is, and was meant by Kant to be, a mere idea. But his ardent love of consistency led him far away from Kant in the end; for he proceeded consistently from the assumption, that whatever we think beyond mental phenomena is ideal, to the logical conclusion that in practical matters our moral responsibility cannot prove the reality of a noumenal freedom, because, as on Kant's assumption we know ourselves from inner sense only as phenomena, we can prove only our phenomenal freedom. Lange thus transmuted inconsistent Kantism into a consistent Neo-Kantism, consisting of these reformed positions: (1) we start with sensations in *à priori* forms; (2) all things known from these data are mental phenomena of experience; (3) everything beyond is idea, without any corresponding reality being knowable. "The intelligible world," he concluded, "is a world of poetry." Our reflection is that there is a great difference between the essence and the consistency of Kant's philosophy. Its essence, as stated by Kant, was to reduce the logical use of reason to mental phenomena of experience in speculation, in order to extend the practical use of reason to the real noumena, or things in themselves, required for morality. Its consistency, as deduced by Lange, was to reduce all use of reason, speculative and practical, to its logical use of proceeding from the assumed mental data of outer and inner sense, arranged *à priori*, to mental phenomena of experience, beyond which we can conceive ideas but postulate nothing. As H. Vaihinger, himself a profound Kantian of the new school, says, "Critical scepticism is the proper result of the Kantian theory of knowledge."

There is only one Neo-Kantian way out of this dilemma, but it is to alter the original assumptions of Kant's psychological idealism. This is the alternative of A. Riehl, who in *Der philosophische Kriticismus* (1876, &c.) proposes the non-Kantian hypothesis that, though things in themselves are unknowable through reason alone, they are knowable by empirical intuition, and therefore also by empirical thought starting from intuition; or, in other words, that we have an immediate perception of an external world. Like all true followers of Kant, Riehl prefers epistemology to metaphysics; and indeed wishes to avoid metaphysics, but really proceeds to found a metaphysics on epistemology, which he calls "critical realism," so far as it asserts a knowledge of things beyond phenomena, and "critical monism," so far as it holds that these things are unlike both physical and psychological phenomena, but are nevertheless the common basis of both. He starts by accepting the Kantian positions that unity of conscious-

ness combines sensations by *à priori* synthesis, and that therefore all that natural science knows about matter moving in space is merely phenomena of outer sense; and he agrees with Kant that from these data we could not infer things in themselves by reason. But his point is that the very sensation of phenomena or appearances implies the things which appear. "Sensory knowledge," he says, "is the knowledge of the relations of things through the relations of the sensations of things." Further, holding that, "like every other perception, the perception of a human body immediately involves the existence of that body," and, like Fichte, believing in a "common consciousness," he concludes that the evidence of sense is verified by "common consciousness" of the external world as objective in the Kantian sense of universally valid. He interprets the external world to be the common basis of physical and psychical phenomena, and so far his "critical realism" reminds us of Trendelenburg's "Lückentheorie" and Dühring's "Wirklichkeitsphilosophie." But whereas Trendelenburg thought that motion is common to thought and being, and Dühring thinks that matter underlies all bodily and mental states, Riehl's view is different, and is founded on his interpretation of Kant. He rightly relies on the numerous passages, neglected by Lange, in which Kant regards things in themselves as neither phenomena nor ideas, but things existing beyond both. But his main reliance is on the passage in the *Kritik*, where Kant, speaking of the Cartesian difficulty of communication between body and soul, suggests that, however body and soul appear to be different in the phenomena of outer and inner sense, what lies as thing in itself at the basis of the phenomena of both may perhaps be not so heterogeneous (*ungleichartig*) after all. Riehl elaborates this bare suggestion into the metaphysical theory that the single basis of physical and psychical phenomena is neither bodily nor mental, nor yet space and motion. In order to establish this paradox of "critical monism," he accepts to a certain extent the psychophysical philosophy of Fechner. He agrees with Fechner that physical process of nerve and psychical process of mind are really the same psychophysical process as appearing on the one hand to an observer and on the other hand to one's own consciousness; and that physical phenomena only produce physical phenomena, so that those materialists and realists are wrong who say that physical stimuli produce sensations. But whereas Fechner and Paulsen hold that all physical processes are universally accompanied by psychical processes which are the real causes of psychical sensations, Riehl rejects this paradox of universal parallelism in order to fall into the equally paradoxical hypothesis that something or other, which is neither physical nor psychical, causes both the physical phenomena of matter moving in space and the psychical phenomena of mind to arise in us as its common effects. In supposing a direct perception of such a nondescript thing, he shows to what straits idealists are driven in the endeavour to supplement Kant's limitation of knowledge to phenomena by some sort of knowledge of things.

(2) *The Reaction to Hume.*—When the Neo-Kantians, led by Lange, had modified Kant's hypothesis of *à priori* forms, and retracted Kant's admission and postulation of things in themselves beyond phenomena and ideas, and that too without proceeding farther in the direction of Fichte and the noumenal idealists, there was not enough left of Kant to distinguish him essentially from Hume. For what does it matter to metaphysics whether by association sensations suggest ideas, and so give rise to ideas of substance and causation *à posteriori*, or synthetic unity of consciousness combines sensations by *à priori* notions of substance and causation into objects which are merely mental phenomena of experience, when it is at

once allowed by the followers of Hume and Kant alike that reason in any logical use has no power of inferring things beyond the experience of the reasoner? In either case, the effective power of inference, which makes us rational beings, is gone. Naturally then the reaction to Kant was followed by a second reaction to Hume, partly under the name of "Positivism," which has attracted a number of adherents, such as C. Göring and E. Laas, and partly under the name of the "Physical phenomenology" of E. Mach.

C. Göring (1841–1879), author of an incomplete *System der Kritischen Philosophie* (1874–1875), recalled Hume's sensationalism by saying that the origin of all knowledge is in sense and no knowledge is possible beyond experience. E. Laas (1837–1885) signalized himself in *Kant's Analogien der Erfahrung* (1876) by his keen criticism of Kant's transcendentalism, and in his later *Idealismus und Positivismus* (1879, &c.) by his clear contrast between Platonism, from which he derived transcendentalism, and Positivism, of which he considered Protagoras to have been the founder. Under the head of Platonism he condemned all belief in mathematical method, in absolute principles, in *à priori*ism, in freedom, and in the transcendent; while Protagoreanism seemed to him to contain three great truths—the inseparability of subject and object, the concomitant variability of both, and the reduction of all higher processes to sensation. He thought that the mantle of Protagoras had descended to Hume and Mill. Now, it is true that the ancient sophistry of Protagoras has issued in the modern sensationalism of Hume, the positivism of Comte, the relativism of Mill, and the universal relativism or correlativism of Laas. Indeed, all these views are varieties of scepticism. Nevertheless, we must not confuse ancient and modern scepticism. Though both asserted a relativity of object and subject, Protagoras thought that there are two different but accompanying streams, the stream of matter and the stream of sense, whereas Hume and Mill positively identified matter with sensations. Now, Laas appealed to Protagoras; but in reality he was a disciple of Hume. So again, if we are to call him a positivist because he believed in nothing but phenomena, we must remember the equivocation of the term "phenomenon." Laas was not so near to the positivism of Comte, who said that the mind can observe all phenomena but its own, as to the psychological positivism of Mill, who thought that it has no other phenomena to observe.

E. Mach (b. 1838) is a conspicuous instance of a confusion of physics and psychology ending in a scepticism like that of Hume. He tells us how from his youth he pursued physical and psychological studies, how at the age of fifteen he read Kant's *Prolegomena*, and two or three years later rejected the thing in itself, and came to the conclusion that the world with his ego is one mass of sensations. For a time, under the influence of Fechner's *Psychophysics*, he thought that Nature has two sides, a physical and a psychological, and added that all atoms have feeling. But in the progress of his physical work, which taught him, as he thought, to distinguish between what we see and what we mentally supply, he soon passed from this noumenalism to a "universal physical phenomenology," which still remains his philosophy. It retains some relics of Fechner's influence; first, the theory of identity, according to which the difference between the physical and psychical is not a dualism, but everything is at once both; and secondly, the substitution of mathematical dependence for physical causality, except that, whereas Fechner only denied causality between physical and psychical, Mach rejects the entire distinction between causality and dependence, on the ground that "the law of causality simply asserts that the phenomena of Nature

are dependent on one another." He comes near to Hume's substitution of succession of phenomena for real causality. He holds, like Hume, that nothing is real except our sensations and complexes of sensory elements; that the ego is not a definite, unalterable, sharply bounded unity, but its continuity alone is important; and that we know no real causes at all, much less real causes of our sensations; or, as he expresses it, bodies do not produce sensations, but complexes of sensations form bodies. If he has any originality, it consists in substituting for the association of ideas the "economy of thinking," by which he means that all theoretical conceptions of physics, such as atoms, molecules, energy, &c., are mere helps to facilitate our consideration of things. But he limits this power of mind beyond sensations to mere ideas, and like Hume, and also like Lange, holds at last that, though we may form ideas beyond sensations or phenomena, we cannot know things. If we ask how Mach arrived at this scepticism, which is contained in his well-known scientific work on the History of Mechanics (*Die Mechanik in ihrer Entwicklung*, 1883) as well as in his psychological work on the Analysis of Sensations (*Beiträge zur Analyse der Empfindungen*, 1886), we find two main causes, both psychological and epistemological; namely, his views on sense and on inference. In the first place, he displays in its most naked form the common but unproved idealistic paradox of a sense of sensations, according to which touch apprehends not pressure but a sensation of pressure, sight apprehends not colour but a sensation of colour, and there is no difference between touch and pressure felt, between vision and colour seen, or between the sensory operation and the sensible object apprehended by any sense, even within the sentient organism. Hence, according to him, sensations are not apprehensions of sensible objects (*e.g.*, pressures felt) from which we infer similar objects beyond sense (*e.g.*, similar pressures of outside things), but are the actual elements out of which everything known is made; as if sensations were like chemical elements. Within the limits of these supposed sensory elements he accords more than many psychologists do to sense; because, following the nativists, Johannes Müller and Hering, he includes sensations of time and space, which, however, are not to be regarded as "pure intuitions" in the style of Kant. But here again he identifies time and space with the sensations of them, which he calls time-sensations (*Zeitempfindungen*) and space-sensations (*Raumempfindungen*). On the assumption, then, that time and space are not objects, but systems, of sensations, he concludes that a body in time and space is "a relatively constant sum of touch-and-light-sensations, joined to the same time-and-space-sensations," that each man's own body is included in his sensations, and that to explain sensations by motions would only be to explain one set of sensations from another. In short, according to Mach sensations are elements and bodies complexes of these elements. Secondly, his theory of inference contains the admission that we infer beyond sensations: he remarks that the space of the geometer is beyond space-sensations, and the time of the physicist does not coincide with time-sensations, because it uses measurements such as the rotation of the earth and the vibrations of the pendulum. But by inference beyond sense he does not mean a process of concluding from sensible things to similar things, *e.g.*, from tangible pressures to other similar pressures in the external world. Inference, according to him, is merely mental completion of sensations; and this mental completion has two characteristics: it only forms ideas, and it proceeds by an "economy of thought." In the course of his learned studies on the History of Mechanics he became deeply impressed

with Galileo's appeals to simplicity as a test of truth. Galileo, for instance, recommended his discovery of the law of the uniform acceleration of a falling body as the "simplest and most natural." But unfortunately he had previously said the same thing about his first and false hypothesis that the uniform acceleration is directly proportional to the space; and, when he resigned the false for the true hypothesis that it is directly proportional to the time, his real evidence was not simplicity, but his carefully conducted experiments of letting bodies fall down inclined planes, and measuring the time by the flow of water. Mach, however, oblivious to these distinctions, converts what is at best only one characteristic of thinking into its essence. Generalization, for instance, which essentially consists in inferring that all similar things of a kind have the attributes of particular instances, does also abbreviate thought by embracing all instances in a universal; but Mach supposes that it essentially consists in this mere economy, and that only an economy of conception, without arriving at true beliefs about things. According to him, whatever inferences we make, certain or uncertain, are mere economies of thought, adapting ideas to sensations, and filling out the gaps of experience by ideas; whatever we infer, whether bodies, or molecules, or atoms, or space of more than three dimensions, are all without distinction equally provisional conceptions, things of thought; and "bodies or things are compendious mental symbols for groups of sensations—symbols which do not exist outside thought." Moreover, he applies the same scepticism to cause and effect. "In Nature," says he, "there is no cause and no effect." He thinks that repetitions of similar conjunctions occur in Nature, the connexion of cause and effect only in abstraction. He refers to Hume as recognizing no causality but only a customary and habitual succession, but adds that Kant rightly recognizes that mere observation cannot teach the necessity of the conjunction. But in reality his theory is neither Hume's theory of association nor Kant's of an *à priori* notion of understanding under which a given case is subsumed. He thinks that there is a notion of understanding (*Verstandesbegriff*), under which every new experience is subsumed, but that it has been developed by former experience, instinctively, and by the development of the race, as part of the economy of thinking. "Cause and effect are therefore," he concludes, "thought-things of economical function (*Gedankendinge von ökonomischer Function*)." His philosophy, therefore, is that all known things are sensations and complexes of sensory elements, supplemented by an economy of thinking which cannot carry us beyond ideas to real things, or beyond relations of dependency to real causes.

It is important to understand that Mach had developed this economical view of thought in 1872, or more than ten years before the appearance of his work on the History of Mechanics in 1883, as he tells us in the preface, where he adds that at a later date similar views were expressed by Kirchhoff in his *Vorlesungen über Mathematische Physik* (1874). Kirchhoff asserted that the whole object of mechanics is "to describe the motions occurring in Nature completely in the simplest manner." This view involves the denial of force as a cause, and the assertion that all we know about force is that the acceleration of one mass depends on that of another, as in mathematics a function depends on a variable; and that even Newton's third law of motion is merely a description of the fact that two material points determine in one another, without reciprocally causing, opposite accelerations. It is evident that Kirchhoff's descriptive is the same as Mach's economical view. "When I say," says Mach, "that a body A exerts a force on a body B, I mean that B, on coming into contraposition with A, is immediately affected by a certain acceleration with

respect to A." In a word, Mach and Kirchhoff agree that force is not a cause, convert Newtonian reciprocal action into mere interdependency, and, in old terminology, reduce mechanics from a natural philosophy of causes to a natural history of mere facts. Now, Mach applies these preconceived opinions to "mechanics in its development," with the result that, though he shows much skill in mathematical mechanics, he misrepresents its development precisely at the critical point of the discovery of Newton's third law of motion, "Actioni contrariam semper et aequalem esse reactionem."

The order of discovery, recorded in the *Philosophical Transactions* of the Royal Society, was as follows:—

(a) Sir Christopher Wren made many experiments before the Royal Society, which were afterwards repeated in a corrected form by Sir Isaac Newton in the *Principia*, experimentally proving that bodies of ascertained comparative weights, when suspended and impelled against one another, forced one another back by impressing on one another opposite changes of velocity inversely as their weights and therefore masses; that is, by impressing on one another equal and opposite changes of momentum.

(b) Wallis showed that such bodies reduce one another to a joint mass with a common velocity equal to their joint momentum divided by their joint weights or masses. This result is easily deducible also from Wren's discovery. If m and m' are the masses, v and v' their initial velocities, and V the common velocity, then

$$\begin{aligned} m(v - V) &= m'(V - v') \\ \therefore mv + m'v' &= (m + m')V \\ \therefore \frac{mv + m'v'}{m + m'} &= V. \end{aligned}$$

(c) Wren and Huyghens further proved that the law of equal action and reaction, already experimentally established by the former, is deducible from the conservation of the velocity of the common centre of gravity, which is the same as the common velocity of the bodies; that is, deducible from the fact that their common centre of gravity does not change its state of motion or rest by the actions of the bodies between themselves; and they further extended the law to bodies, *qua* elastic.

(d) Hence, first inductively and then deductively, the third law was originally discovered only as a law of collision or impact between bodies of ascertained weights and therefore masses, impressing on one another equal and opposite changes of momentum, and always reducing one another to a joint mass with a common velocity to begin with, apart from the subsequent effects of elasticity.

(e) Newton in the *Principia*, repeating and correcting Wren's experiments on collision, and adding further instances from attractive forces of magnetism and gravity, induced the third law of motion as a general law of all forces.

This order of discovery shows that the third law was generalized from the experiments of Wren on bodies of ascertained comparative weights or masses, which are not material points or mass-points. It shows that the bodies impress on one another opposite changes of velocity inversely as their weights or masses; and that in doing so they always begin by reducing one another to a joint mass with a common velocity, whatever they may do afterwards in consequence of their elasticities. The two bodies therefore do not penetrate one another, but begin by acting on one another with a force precisely sufficient, instead of penetrating one another, to cause them to form a joint mass with a common velocity. Bodies then are triply extended substances, each occupying enough space to prevent mutual penetration, and by this force of mutual impenetrability or inter-resistance cause one another to form a joint mass

with a common velocity whenever they collide. Withdraw this foundation of bodies as inter-resisting forces causing one another in collision to form a joint mass with a common velocity but without penetration, and the evidence of the third law disappears; for in the case of attractive forces we know nothing of their *modus operandi* except by the analogy of the collision of inter-resisting bodies, which makes us believe that something similar, we know not what, takes place in gravity, magnetism, electricity, &c. Now, Mach, though he occasionally drops hints that the discovery of the law of collision comes first, yet never explains the process of development from it to the third law of motion. On the contrary, he treats the law of collision with other laws as an application of the third law of motion, because it is now unfortunately so taught in books of mechanics. He has therefore lost sight of the truths that bodies are triply extended, mutually impenetrable substances, and by this force causes which reduce one another to a joint mass with a common velocity on collision, as for instance in the ballistic pendulum; that these forces are the ones we best understand; and that they are reciprocal causes of the common velocity of their joint mass, whatever happens afterwards. In the case of this one force we know far more than the interdependence supposed by Mach and Kirchhoff; we know bodies with impenetrable force causing one another to keep apart. It might have been expected that scepticism on this subject would not have had much effect. But the idealists are only too glad to get any excuse for denying bodily substances and causes; and, while Leibnitz supplied them with the fancied analysis of material into immaterial elements, and Hume with the reduction of bodies to assemblages of sensations, Mach adds the additional argument that bodily forces are not causes at all. In Great Britain, at this moment, Mach's scepticism is welcomed by Karl Pearson to support an idealistic phenomenalism derived from Hume, and by Ward to support a noumenal idealism derived from Lotze. No real advance in metaphysics can take place, and natural science itself is in some danger, until the true history of the evidences of the laws of mechanical force is restored; and then it will soon appear that in the force of collision what we know is not material points determining one another's opposite accelerations, but bodies by force of impenetrable pressure causing one another to keep apart. Mechanics is a natural philosophy of causes.

(3) *Dualism within Experience.*—As it comes to be realized that Hume and Kant agreed more than they differed, German philosophers tend to make new philosophies out of their common points. Hume thought that knowledge has its origin from experience, and Kant that *a priori* elements are contained in this experience; but, in differing about the origin, they agreed about the limits of knowledge, which, according to both, is a knowledge of mental phenomena of sense, and a knowledge limited to objects of experience, without any power of knowing by logical inference anything existing beyond, anything transcending, experience, actual and possible. Now, besides philosophies which are reactions to Kant or to Hume, there are a number of other philosophies in our day which start with this common hypothesis as a principle—knowledge is experience. The consequence is that whatever is true of experience they transfer to all knowledge. One of the characteristics of actual experience is that its object is, or has been, present to an experiencing subject; and of possible experience that it can be present. As a matter of fact, this characteristic differentiates experience from inference. By inference we know that things, such as the farther side of the moon, which neither are, nor have been, nor can be, present to an experiencing subject on the earth, nevertheless exist, and only become objects of inference. But, on the

hypothesis that knowledge contains no inferences beyond experience, it follows that all the objects of knowledge, being objects of experience, are, or have been, or can be, present to an experiencing subject. Hence it is common nowadays to hold that there is indeed a difference between knower and known, ego and non-ego, subject and object, but that they are inseparable; or that all known things are objects and subjects inseparably connected in experience. This view, however, is held in different forms; and two opposite forms have lately arisen in Germany, "immanent philosophy" and "empirio-criticism," the former nearer to Kant, the latter to Hume.

"Immanent philosophy" is the hypothesis that the world is not transcendent, but immanent in consciousness. Among the upholders of this view are Anton von Leclair, who expresses it in the formula—"Denken eines Seins=gedachtes Sein," and R. von Schubert-Soldern, who says that every fragment of the pretended transcendent world belongs to the immanent. But the best known representative of Immanent Philosophy is W. Schuppe, who, in his *Erkenntnistheoretische Logik* (1878), and in his shorter *Grundriss der Erkenntnistheorie und Logik* (1894), gives the view a wider scope by the contention that the real world is the common content or object of common consciousness which, according to him, as according to Fichte, is one and the same in all individual men. Different individual consciousnesses plainly differ in having each its own content, in which Schuppe includes each individual's body as well as the rest of the things which come within the consciousness of each; but they also as plainly agree, e.g., in all admitting one sun. Now, the point of Schuppe is that, so far as they agree, individual consciousnesses are not merely similar, but the same in essence; and this supposed one and the same essence of consciousness in different individuals is what he calls consciousness in general (*Bewusstsein überhaupt*). While in this identification he follows Fichte, in other respects he is more like Kant. He supposes that the conscious content is partly *à posteriori*, or consisting of given data of sense, and partly *à priori*, or consisting of categories of understanding, which, being valid for all objects, are contributed by the common consciousness. He differs, however, from Kant, not only because he will not allow that the given data are received from things in themselves, but also because, like Mach, he agrees with the nativists that the data already contain a spatial determinacy and a temporal determinacy, which he regards as *à posteriori* elements of the given, not, like Kant, as *à priori* forms of sense. He allows, in fact, no *à priori* forms except categories of the understanding, and these he reduces, considering that the most important are identity with difference and causality, which in his view are necessary to the judgments that the various data which make up a total impression (*Gesamteindruck, Totaleindruck*) are each different from the others, together identical with the total impression, and causally connected in relations of necessary sequence and coexistence. At the same time, true to the hypothesis of "immanence," he rigidly confines these categories to the given data, and altogether avoids the inconsistent tendency of Kant to transfer causality from a necessary relation between phenomena to a necessary relation between phenomena and things in themselves as their causes. Hence he strictly confines true judgment and knowledge to the consciousness of the identity or difference, and the causal relations of the given content of the common consciousness. From this epistemology he derives the metaphysical conclusion that the things we know are indeed independent of my consciousness and of yours, taken individually, or, to use a new phrase, are "trans-subjec-

tive"; but, so far from being independent of the common consciousness, one and the same in all of us, they are simply its contents in the inseparable relation of subject and object. To the objection that there are objects, e.g., atoms, which are never given to any consciousness, he returns the familiar Kantian answer that, though unperceived, they are perceptible. The whole known world, then, according to him, is the perceived and the perceptible content of common consciousness. Schuppe has been compared by Wundt with Berkeley. But Schuppe himself distinguishes himself from Berkeley on the ground that, by supposing an object to be the one content of our common consciousness, he explains the unity of an object, which Berkeley's theory of the different ideas of different minds certainly does not; and further, on the ground that he does not, like Berkeley, suppose the will of God to be the direct cause of sensations, but simply regards them as given. The world, according to Berkeley, is immanent in God's consciousness as well as severally in ours; according to Schuppe, it is immanent jointly in ours. Again, this hypothesis of one consciousness reminds us of the Hegelian one reason, the same in God and man. But Schuppe only means one common consciousness uniting the finite consciousnesses of us men. He really descends from Fichte; except that the common consciousness of finite individuals, according to Fichte, by its own activity posits Nature in consciousness itself, but, according to Schuppe, finds Nature given in its own content. From Fichte also comes the supposed inseparability of subject and object. Kant held that the thing in itself can, the thing as object cannot, exist without the synthetic subject. It was Fichte who, identifying thing and object, enunciated the formula—no subject without object and no object without subject, as an exhaustive description not only of knowledge but also of existence. Schuppe reduces the formula from a position of the common ego to a fact of its common experience.

The "empirio-criticism" of R. Avenarius (1843–1896), the former editor of the *Vierteljahrsschrift für wissenschaftliche Philosophie*, is the hypothesis of the inseparability of subject and object, or, to use his own phraseology, of ego and environment, in purely empirical, or *à posteriori* form. It is like "immanent philosophy," in opposing experience to the transcendent; but it also opposes experience to the transcendent, or *à priori*. It opposes "pure experience" to "pure reason," while it agrees with Kant's limitation of knowledge to experience. Avenarius held a view of knowledge very like that of Mach's view of the economy of thinking. In his first philosophical treatise, *Philosophie als Denken der Welt gemäss dem Princip des kleinsten Kraftmaasses, Prolegomena zu einer Kritik der reinen Erfahrung* (1876), he based his views on the principle of least action, contending that, as in Nature the force which produces a change is the least that can be, so in mind belief tends in the easiest direction. In illustration of this tendency, he pointed out that mind tends to assimilate a new impression to a previous content, and by generalization to bring as many impressions under as few general conceptions as possible, and succeeds so far as it generalizes from pure experience of the given. Nor is there any objection to this economical view of thought, as long as we remember what Avenarius and Mach forget, that the essence of thought is the least action neither more nor less than necessary to the point, which is the reality of things. Afterwards, in his *Kritik der reinen Erfahrung* (1888–90), Avenarius aimed at giving a description of pure experience, which he identified with the natural view of the world held by all unprejudiced persons. What, then, is this pure experience? "Every human individual," says he, "originally accepts over against him an environment with manifold parts, other individuals

making manifold statements, and what is stated in some way dependent upon the environment." Statements dependent upon the environment are what he means by pure experience. At first this starting-point looks like dualistic realism, but in reality the author only meant dualism within experience. By the environment he meant not a thing existing in itself, but only a counterpart (*Gegenglied*) of ourselves as central part (*Centralglied*). "We cannot," he adds, "think ourselves as central part away." He went so far as to assert that, where one assumes that at some time there was no living being in the world, all one means is that there was besides oneself no other central part to whom one's counterparts might also be counterparts. The consequence is that all the world admitted into his philosophy is what he called the "empirio-critical essential co-ordination" (*empirio-kritische Prinzipialkoordination*), an inseparable correlation of central part and counterpart, of ego and environment. Within this essential co-ordination he distinguished three values—*R-values* of the environment as stimulus, *C-values* of the central nervous system, and *E-values* of human statements; the latter being characterized by that which at the time of its existence for the individual admits of being named, and including what we call sensations, &c., which depend indirectly on the environment and directly on the central nervous system, but are not, as the materialist supposes, in any way reducible to possessions of the brain or any other part of that system. This division of values brings us to the second point in his philosophy, his theory of what he called "vital series," by which he essayed to explain all life, action, and thought. A vital series he supposed to be always a reaction of C against disturbance by R, consisting in first a vital difference, or diminution by R of the maintenance-value of C, and then the recovery by C of its maintenance-value, in accordance with the principle of least action. He further supposed that, while this independent vital series of C is sometimes of this simple kind, at other times it is complicated by the addition of a dependent vital series in E, by which, in his fondness for too general and far-fetched explanations, he endeavoured to explain conscious action and thought. Thus, if a pain is an E-value directly dependent on a disturbance in C, and a pleasure another E-value directly dependent on a recovery of C, it will follow that a transition from pain to pleasure will be a vital series in E directly dependent on an independent vital series in C, recovering from a vital difference to its maintenance-maximum. Similarly, when in consequence of the stimulus of vibrations of ether, I have a perception of blue, the stimulus R is followed by a vital difference and a recovery of its maintenance-value in C, and this vital series is accompanied by another expressed in the statement E, "I have a perception of blue." Lastly, supposing that all human processes can in this way be reduced to vital series in an essential co-ordination of oneself and environment, Avenarius held that this empirio-critical supposition, which according to him is also the natural view of pure experiences, contains no opposition of physical and psychical, of an outer physical and an inner psychical world—an opposition which seemed to him to be a division of the inseparable. According to him, we should not say that a sensation is in us, but that an E-value is a sign of an object (*e.g.*, blue); and of the relation of object and subject (*e.g.*, perception of blue); nor should we say that the change in C is the cause of another change, E, in us, but only that, if there is a change in C, there is a change in E. He considered that the whole hypothesis that an outer physical thing causes a change in one's central nervous system, which again causes another change in one's inner psychical system or soul, is a departure from the natural view

of the universe, and is due to what he called "introjection," or the hypothesis which encloses soul and its faculties in the body, and then, having created a false antithesis between outer and inner, gets into the difficulty of explaining how an outer physical stimulus can impart something into an inner psychical soul. He concluded therefore that, having disposed of this fallacy of introjection, we ought to return to the view of reality as an essential co-ordination of ego and environment, of central part and counterpart, with R-values, C-values, and E-values. It is curious that Avenarius should have brought forward this artificial hypothesis as the natural view of the world, without reflecting that on the one hand the majority of mankind believes that the environment (R) exists, has existed, and will exist, without being a counterpart of any living being as central part (C); and that on the other hand it is so far from being natural to man to believe that sensation and thought (E) are different from, and merely dependent on, his body (C), that throughout the Homeric poems, though soul is required for other purposes, all thinking as well as sensation is regarded as a purely bodily operation. It is indeed difficult to assign any rational place to the empirio-criticism of Avenarius. It is materialistic without being materialism, because, while it regards the supposition of a soul as due to the fallacy of "introjection," it separates thought from the brain. It is realistic without being realism, because, while it distinguishes R-values, C-values, and E-values, it regards the environment, as well as the nervous system, as existing only in relation to the ego, which cannot think itself away. It borrows tenets of different philosophers,—self-maintenance against disturbance from the realist Herbart, and interdependence without causality between stimulus and ego from the idealist Fechner; while it agrees with Mach's views on the economy of thinking, and in opposition to transcendentalism as well as transcendence. Its rejection of the whole relation of physical and psychical makes it almost too indefinite to classify among philosophical systems. But its main point is the essential co-ordination of ego and environment, as central part and counterpart, in experience. It is therefore nearly connected with "immanent philosophy." Schuppe, indeed, wrote an article in the *Vierteljahrsschrift* of Avenarius to prove their essential agreement. At the same time Schuppe's hypothesis of one common consciousness uniting the given by *à priori* categories could hardly be accepted by Avenarius as pure experience, or as a natural view of the world. His "empirio-criticism" is idealistic dualism within experience in an *à posteriori* form, but with a tendency towards materialism.

(4) *Voluntaristic Phenomenalism of Wundt*.—Wundt's metaphysics will form an appropriate conclusion of this sketch of German idealism, because his patient industry and eclectic spirit have fitted him to assimilate many of the views of his predecessors. Wundt proves, not exactly as Hegel thought that all philosophies are one philosophy, but that all idealisms are in a way one. He starts as a phenomenalist from the hypothesis, which we have just described, that knowledge is experience containing subject and object in inseparable connexion, and has something in common with the premature attempt of Avenarius to develop the hypothesis of dualism in experience into a scientific philosophy comprehending the universe in the simplest possible manner. Again he agrees with the reaction both to Hume and to Kant in limiting knowledge to mental phenomena, and has affinities with Mach as well as with Lange. His main sympathies are with the Neo-Kantians, and especially with Lange in modifying the *à priori*, and in extending the power of reason beyond phenomena to an ideal world; and yet the cry of his phenomenism is not "back to Kant," but "beyond

Kant." Though no noumenalist, in many details he is with noumenalists; with Fechner in psychophysics, in psychophysical parallelism, in the independence of the physical and the psychological chains of causality, in reducing physical and psychical to a difference of aspects, in substituting impulse for accident in organic evolution, and in wishing to recognize a gradation of individual spiritual beings; with Schopenhauer and Hartmann in voluntarism; and even with Schelling and Hegel in their endeavour, albeit on an artificial method, to bring experience under notions, and to unite subject and object in one concrete reality. He has a special relation to Fichte in developing the Kantian activity of consciousness into will and substituting activity for substantiality as the essence of soul, as well as in breaking down the antithesis between phenomena and things in themselves. At the same time, in spite of his sympathy with the whole development of idealism since Kant, which leads him to reject the thing in itself, to modify *à-priorism*, and to stop at transcendent "ideals," without postulates of practical reason, he nevertheless has so much sympathy with Kant's *Kritik* as on its theories of sense and understanding to build up a system of phenomenalism, according to which knowledge begins and ends with ideas, and then on its theory of pure reason to build a crown to his edifice by according to reason a power of logically forming an "ideal" of God as ground of the moral "ideal" of humanity—though without any power of logically inferring any corresponding reality. He constructs his system on the Kantian order—sense, understanding, reason—and exhibits most clearly the necessary consequence from psychological to metaphysical idealism. His philosophy is the best exposition of the method and argument of modern idealism—that we perceive the mental and, therefore, all we know and conceive is the mental. The order of his philosophy is unmistakably as follows:—

(a) Psychology, which he says is, in relation to natural science the supplementary, in relation to mental science the fundamental, in relation to philosophy the propædeutic, empirical science.

(b) Logic and epistemology, whose problem of knowledge he calls the precondition for the answer to all other questions.

(c) Metaphysics, which deals, according to him, with the fundamental principles of all the natural and spiritual sciences, on the foundation of experience, and on a method based on the principle of ground and consequent. Its positive conclusion, drawn from all the previous psychological, logical, and epistemological considerations, is that all we know from sense is ideas (*Vorstellungen*, so translated by himself), distinguishable, but not separable, into subject and object within unitary experience, and dominated by will; while reason logically and necessarily transcends this experience by the principle of ground, but only to form transcendent "ideals" (*Ideen*, to us an untranslatable term), and ultimately the universally valid and necessary "ideal" of God as will of the world (*Weltwille*). Its negative conclusion is that reason has no power to give us a real knowledge of a reality corresponding to the "ideal," and no power in any case of logically inferring things beyond experience, actual and possible. The phenomenal metaphysics of Lange and of Wundt are exceedingly alike; but perhaps we may say that the intelligible world beyond experience is with Lange a world of poetry; with Wundt a world of logic; with both a world of "ideals."

Wundt founds his whole philosophy on four psychological positions—his phenomenalistic theory of unitary experience, his voluntarism, his actualistic theory of soul,

and his psychological theory of parallelism. They are positions also which deeply affect, not only the psychological, but also the metaphysical idealisms of our time, in Germany, and in the whole civilized world. His first position is his phenomenalistic theory of unitary experience. According to him, we begin with an experience of ideas, in which object and idea are originally identical (*Vorstellungsobject*); we divide this unitary experience into its subjective and objective factors, and especially in natural science we so far abstract the objects as to believe them at last to be independent things; but it is the office of psychology to warn us against this popular dualism, and to teach us that there is only a duality of psychical and physical, which are divisible, not separable, factors of one and the same content of our immediate experience; and experience is our whole knowledge. His metaphysical deduction from this psychological view is that all we know is mental phenomena, "the whole outer world exists for us only in our ideas," and all that our reason can logically do beyond these phenomena is to frame transcendent "ideals." His second position is his voluntarism. He agrees with Schopenhauer that not intellect but will is the fundamental form of the spiritual (*die Grundform des Geistigen*). He does not mean that will is the only mental operation; for he recognizes idea derived from sensation, and feeling, as well as will. Moreover, he contends that we can neither have idea without feeling and will, nor will without idea and feeling; that idea alone wants activity, and will alone wants content; and that will is ideating activity (*vorstellende Thätigkeit*), which always includes motives and ends and therefore ideas. He is therefore a follower of Schopenhauer as corrected by Hartmann. Like these predecessors, and like his younger contemporary Paulsen, in calling will fundamental he includes impulse (*Trieb*). Accordingly he divides will into two species; on the one hand, simple volition, or impulse, which in his view requires as motive a feeling directed to an end, and therefore an idea, e.g., the impulse of a beast arising from hunger and sight of prey; on the other hand, complex volition issuing in a voluntary act, requiring decision (*Entscheidung*) or conscious adoption of a motive, with or without choice. Like other German voluntarists, he imputes "impulsive will" to the whole organic world. He holds that not only reflex action in animals, but also irritability in plants is originally an impulse which becomes secondarily automatic; that the protozoon acts in all its parts by "will-impulses," as well as in its whole organism; and that the simplest forms of life are impulsive animals from which plants are developed as chlorophyll-producing organisms. He follows Fechner closely in his answer to Darwin. If he is to be believed, at the bottom of all organic evolution, organic impulses becoming habits produce structural changes, which are transmitted by heredity; and as an impulse thus gradually becomes secondarily automatic, the will passes to higher activities, which in their turn become secondarily automatic, and so on. As now he supposes feeling even in "impulsive will" to be directed to an end, he deduces the conclusion that in organic evolution the pursuit of final causes precedes and is the origin of mechanism. But at what a cost! He has endowed all the plants in the world with motives, feelings directed to an end, and ideas, all of which, according to him, are required for impulse! He apparently forgets that mere feelings often produce actions, as when one writhes with pain. But even so, have plants even those lowest impulses from feelings of pain or pleasure? Wundt, however, having gone so far, there stops. It is not necessary for him to follow Schopenhauer, Hartmann, and Fechner in endowing the material universe with will or any other mental operation, because his phenomenalism already reduces inorganic

nature to mere objects of experiencing subjects. Wundt's voluntarism takes a new departure, in which, however, he was anticipated by the paradox of Descartes that will is required to give assent to anything perceived (*Principia Philosophiæ*, i. 34). Wundt supposes not only that all organisms have outer will, the will to act, but also that all thinking is inner will, the will to think. Now, there is a will to think, and Aristotle pointed out that thinking is in our power whenever one pleases, whereas sense depends on an external stimulus (*De Anima*, ii. 5). There is also an impulse to think, e.g., from toothache. But it does not follow that thought is will, or even that there is no thinking without either impulse or will proper. The real source of thinking is evidence. Wundt, however, having supposed that all thinking consists of ideas, next supposes that all thinking is willing (*jedes Denken ein Wollen*). What is the source of this paradox? It is a confusion of impulse with will, and activity with both. He supposes that all agency, and therefore the agency of thinking, is will. In detail, to express this supposed inner will of thinking, he borrows from Leibnitz and Kant the term "apperception," but in a sense of his own. Leibnitz, by way of distinction from unconscious perception, gave the name "apperception" to consciousness, or the reflective knowledge of our inner states which, according to his monadology, is not given to all souls, nor always to the same soul. Kant further insisted that this apperception, "I think," is an act of spontaneity, distinct from sense, necessary to regarding all my ideas as mine, and to combining them in a synthetic unity of apperception; which act Fichte afterwards developed into an active construction of all knowledge, requiring will directed to the end of duty. Wundt, in consequence, thinking with Kant that apperception is a spontaneous activity, and with Fichte that this activity requires will, and indeed that all activity is will, infers that apperception is inner will. Further, on his own account, he identifies apperception with the process of attention, and regards it as an act necessary to the general formation of compound ideas, to all association of ideas, to all imagination and understanding. According to him, then, attention, even involuntary attention, requires inner will; and all the functions imputed by Hume to association, as well as those imputed to understanding by Kant, require apperception, and therefore inner will. At the same time, he does not suppose that they all require the same kind of will. In accordance with his previous division of outer will into impulsive and decisive, he divides the inner will of apperception into (1) passive apperception, or impulsive will necessary to association, passive in receiving the content of sensations, but active so far as this content is a motive rousing it to ideating activity, and (2) active apperception, or decisive will necessary to understanding, and giving rise to what he awkwardly calls "apperceptive combinations," among which come judgments. Apperception in general thus becomes activity of inner will, constituting the process of attention, passive in the form of impulsive will required for association, and active in the form of decisive will required for understanding and judgment. Now, beneath these confusing phrases the point to be regarded is that, in Wundt's opinion, though we can receive sensations, we cannot think at all beyond sense, without some will; we cannot form any compound idea, or any association of ideas without impulse, and we cannot make any comparison or any judgment without decision, and a decision, not in the intellectual sense of a conclusion from evidence, but on the practical sense of a conscious adoption of a motive. This exaggeration of the real fact of the will to think ignores throughout the position of little man in the great world and at the mercy of things which drive him perforce to sense

and from sense to thought. (See article on Logic.) It is a substitution of will for evidence as ground of assent, and a neglect of our consciousness that we often believe against our will (e.g., that we must die), often without even an impulse to believe, often without taking any interest, or when taking interest in something else of no importance. "The Dean is dead (Pray, what is trumps?)." Yet many psychologists accept the universality of this will to believe, and among them James, who says that "it is far too little recognized how entirely the intellect is built up of practical interests." We should rather say "far too much." Wundt, however, goes still farther. According to him, that which acts in all organisms, that which acts in all thinking, that which divides unitary experience into subject and object, the source of self-consciousness, the unity of our mental life, the most proper being of the individual subject, is will (*das eigenste Sein des einzelnen Subjectes das Wollen ist*). In short, his whole voluntarism means that, while the inorganic world is mere object, all organization is congealed will, and all thinking is apperceptive will. But it must be remembered that these conclusions are arrived at by confusing action, reaction, life, excitability, impulse, and rational desire, all under the one word "will," as well as by omitting the involuntary action of intelligence under the pressure of evidence. Nothing is gained by obliterating the distinctions between physical agency of which vegetative excitability and reflex action are instances, instinctive action from feeling, and voluntary action of will from reason and desire of end. It may well be that impulsive feeling is the beginning of mind; but then the order of mind is feeling, sense, inference, will, which instead of first is last, and implies the others. To proceed, however, with voluntarism, Wundt, as we have seen, makes personality turn on will. He does not accept the universal voluntarism of Schopenhauer and Hartmann, but believes in individual wills, and a gradation of wills, in the organic world. The protozoon, he says, has "will-impulses" in its parts, as well as in the whole organism. Similarly, he supposes, our personal individual will is a collective will containing simpler will-unities, and he thinks that this conclusion is proved by the continuance of actions in animals after parts of the brain have been removed. In a similar way, he supposes, our wills are included in the collective will of society. He does not, however, think with Schuppe that there is one common consciousness, but only that there is a collective consciousness and a collective will; not perceiving that then the sun, in his view a mere object in the experience of every member of the collection, would be only a collective sun. Lastly, he believes that reason forms the "ideal" of God as world-will, though without proof of existence. On the whole, his voluntarism, though like that of Schopenhauer and Hartmann, is not the same; not Schopenhauer's, because the ideating will of Wundt's philosophy is not a universal irrational will; and not Hartmann's, because, although ideating will, according to Wundt's phenomenalism, is supposed to extend through the world of organisms, the whole inorganic world remains a mere object of unitary experience. His third position is his actualistic theory of soul, which need not detain us, as he shares it with Fichte, Hegel, Fechner, and Paulsen. When Fichte had rejected the Kantian soul in itself and developed the Kantian activity of apperception, he considered that soul consists in constructive activity. Fechner added that the soul is the whole unitary spiritual process manifested in the whole unitary bodily process without being a substance. Wundt accepts Fichte's theory of the actuality, and Fechner's synechological view, of the soul. Taking substance entirely in the sense of substrate, he argues that there is no evidence of a substantial substrate beneath

mental operations; that there is nothing except unitary experience consisting of ideas, feelings, volitions, and their unity of will; and that soul in short is not *substantia*, but *actus*. He does not see that this unity is only apparent, for men think not always, and will not always. Nor does he see that a man is conscious not of idea, feeling, will, experience, but of something conceiving, feeling, willing, and experiencing, which he gradually learns to call himself, and that he is never conscious of doing all this "minding" without his body. If, then, these mental operations were merely actuality, they would be actuality of a man's bodily substance. In truth, there is no sound answer to Materialism, except that, besides bodily substance, psychical substance is also necessary to explain how man performs mental actualities consciously (see *Physical Realism*, ch. v.). Wundt, however, has satisfied himself, like Fechner, that there is no real opposition of body and soul, and concludes, in accordance with his own phenomenalism, that his body is only an object abstracted from his unitary experience, which is all that really is of him. Hence his fourth point is his psychological theory of parallelism of physical and psychical reduced to identity in unitary experience. Here his philosophy is Fechnerism phenomenalized. He delivered a well-deserved encomium on Fechner's experimental psychology at his master's grave. He accepts Fechner's extension of Weber's law of the external stimuli of sense, while judiciously remarking that "the physiological interpretation is entirely hypothetical." He accepts psychophysical parallelism in the sense that every psychical process has a physical accompaniment, every physiological function has a psychical meaning, but neither external stimulus nor physiological stimulus is cause of a psychical process, nor *vice versa*. Precisely like Fechner, he holds that there is a physical causality and energy, and there is a psychical causality and energy, parallels which never meet. He uses this psychical causality to carry out his voluntarism into detail, regarding it as an agency of will directed to ends, causing association and understanding, and further acting on a principle which he calls the heterogony of ends; remarking very truly that each particular will is directed to particular ends, but that beyond these ends effects follow as unexpected consequences, and that this heterogony produces social effects, which we call custom. But while thus sharply distinguishing the physical and the psychical in appearance, he follows Fechner in identifying them in reality; except that Fechner's identification is noumenal, Wundt's phenomenal. Wundt does not allow that we know beyond experience any souls of earth, or any other inorganic being. He does not, therefore, allow that there is a universal series of physical and psychical parallels. According to his phenomenalism, the external stimulus and the physiological stimulus are both parallels of the same psychical process; the external body, as well as my body, is merely an object abstracted from an idea of my experience; and what is really known in every case is a unitary experience divisible, but not separable, into body and soul, physical and psychical factors of one and the same unitary experience. Wundt is confined by his starting-point to his deduction that what we know is mental phenomena, ideas regarded as objects and subjects of experience.

With these four positions in hand, Wundt's philosophy consecutively follows, beginning with his psychology. I am conscious of having sensations of pressure between the members of my body, and of inferring similar pressures between my body and external bodies, and between external bodies themselves. I am conscious of having other sensations of heat, colour, sound, odour, flavour, and of inferring that the same external body, *e.g.*, an orange, which causes in me sensible pressure, causes in me these other sensible

effects. I am conscious that I never perceive any of these sensible objects except as enduring temporally, or any pressure or colour except as extended spatially; and that I feel triply-extended pressure, as when I suck my tongue or clench my fist. I am conscious that I infer distinct triply-extended bodies, *e.g.*, an orange. I am not conscious of fusing my sensations and ideas into a compound object. I am conscious that I have acquired a habit of confusing my sensations, ideas, inferences; but that I can distinguish them by consciousness. In defiance of these conscious facts Wundt constructs his psychology. He begins with psychical elements, sensations and feelings, but he asserts that these always exist in a psychical compound, from which they can be discovered only by analysis and abstraction; and his paradox that "*a pure sensation is an abstraction*" is repeated by W. James. Further, Wundt declares that the psychical compound of sensations, with which, according to him, we actually start, is not a complex sensation, but a compound idea; so that I am expected to believe that, when I hear the chord of D, I am not conscious of single sensations of D, F, A, and have only a compound idea of the chord—as if the hearing of music were merely a series of ideas! Wundt, however, has a reason for substituting compound idea for sensation: he accepts Lotze's hypothesis of local signs, and adds a hypothesis of temporal signs. He supposes that we have no sensations of space and time, as the nativists suppose, but that, while local signs give us spatial ideas, feelings of expectation are temporal signs giving us temporal ideas, and that these ideas enter into the psychical compound, which is our actual starting-point. It follows that every psychical compound into which temporal and spatial ideas enter must itself be an idea; and, as time at any rate accompanies all our sensations, it follows that every psychical compound of sensations, containing, as it does, always temporal, if not also spatial, ideas, must be a compound idea, and not, as nativists suppose, Schuppe for instance, a compound sensation. The next question is, how compounded? Wundt's answer is that inner impulse will, in the form of passive apperception, forms compound ideas by association; so that all these operations are necessary to the starting-point. He prefixes to the ordinary associations, which descend from Hume, an association which he calls fusion (*Verschmelzung*), and supposes that it is a fundamental process of fusing sensations with spatial and temporal ideas into a compound idea. But he also recognizes association by similarity, or assimilation, or "apperception" in Herbart's more confined sense of the word, and association by contiguity, or complication. Recognizing, then, three kinds of association in all, he supposes that they are the first processes, by which inner will, in the form of passive apperception, generates ideas from sense. So far his psychology is a further development of Hume's. But he does not agree with Hume that mind is nothing but sensations, ideas, and associations, but with Kant, that there are higher combinations. According to him, inner decisive will, rising to active apperception, proceeds to what he calls "apperceptive combinations" (*Apperceptionverbindungen*); first to simple combinations of relating and comparing, and then to complex combinations of synthesis and analysis in imagination and understanding; in consequence of which synthesis issues in an aggregate idea (*Gesamtvorstellung*), and then at last analysis, by dividing an aggregate idea into subject and predicate, forms a judgment. For a criticism of this extraordinary theory of judgment we may refer to the article on Logic. At present the main point is that, if it were true, we should be for ever confined to a jumble of ideas. Wundt, indeed, is aware of the consequences. If judgment is an analysis

of an aggregate idea into subject and predicate, it follows, as he says, that "as judgment is an *immediate*, so is inference a *mediate*, reference of the members of any aggregate of ideas to one another" (*System der Philosophie*, 66, first ed.). He cannot allow any inference of things beyond ideas. His psychology poisons his logic.

In his logic, and especially in his epistemology, Wundt appears as a mediator between Hume and Kant, but with more leaning to the latter. While he regards association as lying at the basis of all knowledge, he does not think it sufficient, and objects to Hume that he does not account for necessity, nor for substance and causation as known in the sciences. He accepts on the whole the system of synthetic understanding which Kant superimposed on mere association. He agrees with Kant about the spontaneous activity of apperception, which he develops into inner will to think. Unlike Hume, but like Kant, he distinguishes between an idea and a judgment so far as the latter involves a bifurcation into subject and predicate; and consequently he regards the processes by which we form judgments as not passive associations of ideas but active synthesis and analysis. Once more, he agrees with Kant that the function of understanding consists in "the interpretation of experience by its arrangement under common notions." He does not think that all these notions are empirical, or contained in the primary ideas of unitary experience, or in the object of idea (*Vorstellungsobject*) in which idea and object are as yet undistinguished. Yet he will not proceed to the length of Kant's transcendentalism, but says that "an *à priori* of forms of intuition and notion in the Kantian sense cannot be rightly maintained" (*System*, 202). Between Hume's *à posteriori* and Kant's *à priori* hypothesis, he proposes a *logical* theory of the origin of notions beyond experience. He explains that the arrangement of facts requires "general supplementary notions (*Hilfsbegriffe*), which are not contained in experience itself, but are gained by a process of logical treatment of this experience." Of these supplementary notions he holds that the most general is that of causality, coming from the necessity of thought that all our experiences shall be arranged according to ground and consequent. That sense only gives to experience coexistences and sequences of appearances, as Hume said and Kant allowed, is also Wundt's starting-point. How then do we arrive at causality? Not, says Wundt, by association, as Hume said, but by thinking; not, however, by *à priori* thinking, as Kant said, but by logical thinking, by applying the logical principle of ground and consequent (which Leibnitz had called the principle of sufficient reason) as a causal law to empirical appearances. Now, Wundt is aware that this is not always possible, for he holds that the logical principle of ground belongs generally to the connexion of thoughts, the causal law to the combination of empirical appearances. Nevertheless he believes that, when we can apply measures to the combination of empirical appearances, then we can apply the logical principle as causal law to this combination, and say that one appearance is the cause of another, thus adding a notion of causality not contained in the actual observations, but specializing the general notion of causality. He quotes as an instance that Newton in this way added to the planetary appearances contained in Kepler's laws the gravitation of the planets to the sun, as a notion of causality not contained in the appearances, and thus discovered that gravitation is the cause of the appearances. But Newton had already discovered beforehand in the mechanics of terrestrial bodies that gravitation constantly causes similar facts on the earth, and did not derive that cause from any logical ground beyond experience, any more than he did the third law of

motion. Wundt does not realize that, though we can often use a cause or real ground (*principium essendi*) as a logical ground (*principium cognoscendi*), for deducing effects, we can do so only when we have previously inferred from experience that that kind of cause does produce that kind of effect (see article on LOGIC). Otherwise, logical ground remains logical ground, as in any non-causal syllogism, such as the familiar one from "All men are mortal," which causes me to know that I shall die, without telling me the cause of death. Wundt, however, having satisfied himself of the power of mere logical thought beyond experience, goes on to further apply his hypothesis, and supposes that, in dealing with the physical world, logical thinking having added to experience the "supplementary notion" of causality as the connexion of appearances which vary together, adds also the "supplementary notion" of substance as substratum of the connected appearances. But, using substance as he does always in the Kantian sense of permanent substratum beneath changing phenomena, and never in the Aristotelian sense of any distinct thing, he proceeds to make distinctions between the applications of causality and of substance. Even in the physical, he confines substance to matter, or what Aristotle would call material causes, thus makes its power to be merely passive, and limits substantial causality to potential energy, while he supposes that actual causality is a relation not of substances but of events. On this false abstraction Sigwart has made an excellent criticism in an appendix at the end of his *Logic*, where he remarks that we cannot isolate events from the substances of which they are attributes. Motions do not cause motions; one body moving causes another body to move: what we know is causal substances. Secondly, when Wundt comes to the psychical, he naturally infers from his narrow Kantian definition of substance that there is no proof of a substrate over and above all mental operations, and falsely thinks that he has proved that there is no substance mentally operating in the Aristotelian sense. Thirdly, on the grounds that logical thinking adds the notion of substance, as substrate, to experience of the physical, but not of the psychical, and that the most proper being of mind is will, he concludes that wills are not active substances, but substance-generating activities ("nicht thätige Substanzen sondern substanzerzeugende Thätigkeiten," *System*, 429).

What kind of metaphysics, then, follows from this compound of psychology and epistemology? As with Kant against Hume, so with Wundt against Mach and Avenarius, the world we know will contain something more than mere complexes of sensations, more than pure experience: with Wundt it will be a world of real causes and some substances, constituted partly by experience and partly by logical thinking, or active inner will. But as with Kant, so with Wundt, this world will be only the richer, not the wider, for these notions of understanding; because they are only contributed to the original experience, and, being mentally contributed, only the more surely confine knowledge to experience of mental phenomena. Hence, according to Wundt, the world we know is still unitary experience, distinguished, not separated, into subject and object, aggregates of ideas analysed by judgment and combined by inference, an object of idea elaborated into causes and substances by logical thinking, at most a world of our ideas composed out of our sensations, and arranged under our categories of our understanding by our inner wills, or a world of our ideating wills; but nothing else. It is Wundt's own statement of his solution of the epistemological problem "that on the one hand the whole outer world exists for us only in our ideas, and that on the other hand a consciousness without objects of idea is an empty abstraction which possesses no actuality"

(*System*, 212–213). There remains his theory of reason. His pupil, O. Külpe, who bases his *Grundriss der Psychologie* on the hypothesis of unitary experience, says in his *Einleitung in die Philosophie* (1895) that Wundt in his *System* derives the right of metaphysics to transcend experience from similar procedure within the limits of the special sciences. This is Wundt's view, but only in the sense that reason passes from ideas to "ideals," whether in the special sciences or in metaphysics. Reason, as in most modern psychologies and idealisms, is introduced by Wundt, after all sorts of operations, too late; and, when at length introduced, it is described as going beyond ideas and notions to "ideals" (*Ideen*), as an ideal continuation of series of thoughts beyond given experience—nothing more. Reason, according to Wundt, is like pure reason according to Kant; except that Wundt, receiving Kantism through Neo-Kantism, thinks that reason arrives at "ideals" not *à priori*, but by the logical process of ground and consequent, and, having abolished the thing in itself, will not follow Kant in his inconsequent passage from pure to practical reason in order to postulate a reality corresponding to "ideals" beyond experience. Wundt, in fact, agrees with Lange that reason transcends experience of phenomena only to conceive "ideals." This being so, he finds in mathematics two kinds of transcendence—real, where the transcendent, though not actual in experience, can become partly so, *e.g.*, the divisibility of magnitudes; imaginary, where it cannot, *e.g.*, *n*-dimensions. He supposes in metaphysics the same transcendence in forming cosmological, psychological, and ontological "ideals." He supposes real as well as imaginary transcendence in cosmological "ideals"; the former as to the forms of space and time, the latter as to content, *e.g.*, atoms. But he limits psychological and ontological "ideals" entirely to imaginary transcendence ("die psychologischen und ontologischen Ideen dagegen fallen ganz und gar dem Gebiet imaginärer Transcendenz zu"). The result is that he confines metaphysical transcendence to "a process into the imaginary" as regards the substantial and causal content of cosmological "ideals," and altogether as regards psychological and ontological "ideals." Thus, according to him, in the first place reason forms a cosmological "ideal" of a multitude of simple units related; secondly, it forms a psychological "ideal" of a multitude of wills, or substance-generating activities, which communicate with one another by ideas so that will causes ideas in will, while together they constitute a collective will, and it goes on to form the moral ideal of humanity (*das sittliche Menschheitsideal*); and thirdly, it forms an ontological "ideal" of God as ground of this moral "ideal," and therewith of all being as means to this end, and an "ideal" of God as world-will, of which the world is development, and in which individual wills participate each in its sphere. "Herein," says Wundt, "consists the imperishable truth of the Kantian proposition that the moral order of the world is the single real proof of the existence of God" (*System*, 405, cf. 439). "Only," he adds, "the expression *proof* is here not admissible. Rational 'ideals' are in general not provable." As the same limit is applied by him to all transcendent rational "ideals," and especially to those which refer to the content of the notion of the world, and, like all psychological and ontological "ideals," belong to the imaginary transcendent, his conclusion is that reason, in transcending experience, logically conceives "ideals," but never logically infers corresponding realities. He contends, indeed, that at least the moral "ideal" of humanity and the ontological "ideal" of God are universally valid, and that therefore reason alone can give an account of them. But what account? "While in this way philo-

sophical inquiry exhibits the ground of their universal validity, it indicates at the same time the 'ideals' themselves as *necessary*. To contribute more it is neither called nor capable. Especially must it completely abstain from exhibiting besides that necessity of the 'ideal' also the necessity of a *reality* corresponding to the idea. Philosophy can prove the necessity of faith; to convert it into knowledge is beyond its power." These are the concluding words of the part of his *System der Philosophie* (1889) which deals with metaphysics.

The conclusion that reason in transcending experience can show no more than the necessity of "ideals" is the only conclusion which could follow from Wundt's phenomenalism in psychology, logic, and epistemology. If knowledge is experience of ideas distinguished by inner will of apperception into subject and object in inseparable connexion, if the starting-point is ideas, if judgment is analysis of an aggregate idea, if inference is a mediate reference of the members of an aggregate of ideas to one another, then, as Wundt says, all we can know, and all reason can logically infer from such data, is in our ideas, and consciousness without an object of idea is an abstraction; so that reason, in transcending experience, can show the necessity of ideas and "ideals," but infer no corresponding reality beyond, whether in Nature, or in Man, or in God. Wundt, starting from a psychology of unitary experience, deduces a consistent metaphysics of no inference of things transcending experience throughout,—or rather until he comes to the very last sentence quoted above, when he suddenly passes from a necessity of "ideals" (*Ideen*), to a necessity of "faith" (*Glauben*), without "knowledge" (*Wissen*). He forgets apparently that faith is a belief in things beyond ideas and ideals, which is impossible on his psychology of judgment and logic of inference. The fact is that his *System* may easily seem to prove more than it does. He describes it as idealism in the form of ideal realism, because it recognizes an ideating will requiring substance as substratum or matter for outer relations of phenomena. But when we look for the evidence of any such will beyond ourselves and our experience, we find Wundt offering nothing but an ontological "ideal" of reason, and a moral "ideal" requiring a religious "ideal," but without any power of inferring a corresponding reality. The *System* then ends with the necessity of an "ideal" of God as world-will, but provides no ground for the necessity of any belief whatever in the being of God, or indeed in any being at all beyond our own unitary experience.

Wundt, however, has since written an *Einleitung in die Philosophie* (1901), in which he speaks of realism in the form of ideal realism as the philosophy of the future. It is not to be idealism which resolves everything into spirit, but realism which gives the spiritual and the material each its own place in harmony with scientific consciousness. It is not to be dualistic but monistic realism, because matter is not separate from spirit. It is not to be materialistic but ideal realism, because the physical and the psychical are inseparable parallels inexplicable by one another. It is to be monistic ideal realism, like that of Fichte and Hegel; not, however, like theirs idealistic in method, a *Phantastisches Begriffsgebäude*, but realistic in method, a *Wissenschaftliche Philosophie*. It is to be ideal realism, as in the *System*. It is not to be a species of idealism, as in the *System*,—but of realism. How are we to understand this change of front? We can only explain it by supposing that Wundt wishes to believe that, beyond the "ideal," there really is *proof* of a transcendent, ideating, substance-generating will of God; and that he is approaching the noumenal voluntarism of his younger contemporary, Paulsen. But to make such a

conversion from phenomenalism plausible, it is necessary to be silent about his whole psychology, logic, and epistemology, and the consequent limitation of knowledge to experience, and of reason to ideas and "ideals," without any power of inferring corresponding things.

What a pity it is that Wundt had committed himself by his psychology to phenomenalism, to unitary experience, and to the limitation of judgment and reason to ideas and "ideals"! For his phenomenalism prevents him from consistently saying the truth inferred by reason, that there is a world beyond experience, a world of Nature, and a will of God, real as well as ideal. To understand Wundt is to discover what a mess modern psychology has made of metaphysics. To understand phenomenal idealism in Germany is to discover what a narrow world is to be known from the transcendental idealism of Kant shorn of Kant's inconsistencies. To understand noumenal idealism in Germany and the rise of metaphysical idealism in modern times is to discover that psychological is the origin of all metaphysical idealism. If we perceive only what is mental, all that we know is only mental. But who has proved that psychological starting-point? Who has proved that, when I scent an odour in my nostrils, I apprehend not odour but a sensation of odour; that when I taste a flavour in my mouth, I apprehend not flavour but a sensation of flavour; that, when I hear a sound in my ears, I apprehend not sound but a sensation of sound; that, when I see a colour in my eyes, I apprehend not colour but a sensation of colour; that, when I feel a pressure and heat in my body, I apprehend not pressure and heat but a sensation of pressure and of heat? Sensation, as Aristotle said, is not of itself: it is the apprehension of a sensible object in the organism. I perceive pressure, heat, colour, sound, flavour, odour, in my five senses. Having felt reciprocal pressures in touch, I infer similar pressures between myself and the external world.

§ 6. RECENT ENGLISH IDEALISM.

(1) *The Followers of Hume's Phenomenalism.*—Compared with the great systems of the Germans, English idealism in the 19th century shows but little originality. It has been largely borrowed either from previous English or from later German idealism, and what originality it has possessed has been mainly shown in that spirit of eclectic compromise which is so dear to the English mind. The predominant influence, on the whole, has been the phenomenalism of Hume, with its slender store of sensations, ideas, and associations, and its conclusion that all we know is sensations without any known thinkers or any other known things. This phenomenalism was developed by James Mill (1773-1836) and J. S. Mill (1806-1873), and has since been continued by A. Bain. It also became the basis of the philosophies of Huxley and of Spencer on their phenomenalistic side. It is true that Spencer's "transfigured realism" contains much that was not dreamt of by Hume. Spencer widens the empirical theory of the origin of knowledge by his brilliant hypothesis of inherited organized tendencies, which has influenced all later psychology and epistemology, and tends to a kind of compromise between Hume and Kant. He describes his belief in an unknowable absolute as "carrying a step farther the doctrine put into shape by Hamilton and Mansel." He develops this belief in an absolute in connexion with his own theory of evolution into something different both from the idealism of Hume and the realism of Hamilton, and rather falling under the head of materialism. Nevertheless, as he believes all the time that everything knowable throughout the whole world of evolution is phenomena in the sense of subjective affections

of consciousness, and as he applies Hume's distinction of impressions and ideas as a distinction of vivid and faint states of consciousness to the distinction of ego and non-ego, spirit and matter, inner and outer phenomena, his philosophy of the world as knowable remains within the limits of phenomenalism. Nothing could be more like Hume than his final statement that what we are conscious of is subjective affections produced by objective agencies unknown and unknowable. The "anti-realism," which takes the lion's share in "transfigured realism," is simply a development of the phenomenalism of Hume. Hume was also at the bottom of the philosophies of G. H. Lewes, who held that there is nothing but feelings, and of W. K. Clifford. Nor is Hume yet dethroned, as we see from the works of Karl Pearson and of William James, who, though an American, is exercising a considerable influence on English thought. The most flourishing time of phenomenalism, however, was during the lifetime of J. S. Mill. It was counteracted to some extent by the study at the universities of the deductive logic of Aristotle and the inductive logic of Bacon, by parts of Mill's own logic, and by the natural realism of Reid, Stewart, and Hamilton, which met Hume's scepticism by asserting a direct perception of the external world. But natural realism, as finally interpreted by Hamilton, was too dogmatic, too unsystematic, and too confused with elements derived from Kantian idealism to withstand the brilliant criticism of Mill's *Examination of Sir William Hamilton's Philosophy* (1865), a work which for a time almost persuaded us that Nature as we know it from sensations is nothing but permanent possibilities of sensation, and oneself only a series of states of consciousness.

(2) *The Influence of Kant and Hegel.*—Nevertheless, there have never been wanting more soaring spirits who, shocked at the narrowness of the popular phenomenalism of Hume, have tried to find a wider idealism. They have, as a rule, sought it in Germany. Before the beginning of the 19th century, Kant had made his way to England in a translation of some of his works, and in an account of the *Elements of the Critical Philosophy* by A. F. M. Willich, both published in 1798. After a period of struggle, the influence of Kant gradually extended, and, as we see in the writings of Coleridge and Carlyle, of Hamilton and Mansel, of Green and Caird, of Laurie and Martineau, has secured an authority over English thought almost equal to that of Hume, with whom, indeed, Kant had much in common. Both philosophers appeal to the English love of experience, and Kant had these advantages over Hume, that within the narrow circle of sensible phenomena his theory of understanding gave to experience a fuller content, and that beyond phenomena, however inconsistently, his theory of reason postulated the reality of God, freedom, and immortality. Other and wider German philosophies gradually followed that of Kant to England. Coleridge (1772-1834) not only called attention to Kant's distinction between understanding and reason, but also introduced his countrymen to the noumenal idealism of Schelling. In the *Biographia Literaria* (1817) he says that in Schelling's *Naturphilosophie* and *System des transcendentalen Idealismus* he first found a general coincidence with much that he had toiled out for himself, and he repeated some of the main tenets of Schelling. Carlyle (1795-1881) laid more emphasis on Fichte. At the height of his career, when between 1840 and 1850 many of Fichte's works were being translated in the Catholic Series, he called attention to Fichte's later view that all earthly things are but as a vesture or appearance under which the Divine idea of the world is the reality. Extravagant as this noumenalism is, it was a healthy antidote to the phenomenalism of the day. Not

long afterwards, J. F. Ferrier (1808–1864) published his *Institutes of Metaphysics* (1854). Ferrier held a theory that reality is “thing-mecum,” or object *plus* subject, which reminds us of Fichte and his successors. The key to his metaphysics is that, starting from Hamilton’s theory that what we know is always the ego and the non-ego in inseparable connexion, he also imbibed Hamilton’s love of historical research, and affected by the Germans through Hamilton, gradually deserted his master. Thus he did not agree with Hamilton, but with Schelling, about the absolute. Schelling asserted that we know the absolute by an intellectual intuition which we have in common with it, Hamilton that by the constitution of our faculties we know only the conditioned. Ferrier perceived that the victory is with Schelling, if there is a common intelligence, and not only accepted this condition, but also founded his lectures on Greek philosophy on the assumption that absolute truth is truth for this universal intelligence, and that the object of philosophy is to find this absolute truth. Ferrier then ended with the hypothesis of Schelling and Hegel that there is one absolute intelligence (see Ferrier, *Lectures and Philosophical Remains*, 1866, i. 1–33; ii. 545–68). In 1865 his compatriot J. Hutchison Stirling published *The Secret of Hegel*. While the Scottish philosophers were thus passing from natural realism to the noumenal idealism of Schelling and Hegel, B. Jowett (1817–1893), then tutor of Balliol College, Oxford, had been studying the philosophy of Hegel, as we learn from his *Life* by Campbell and Abbott (i. 90–92). Throughout his life he continued to admire the flashes which illuminate the obscurity, and the habit of looking at both sides of the question which palliates the confusion, of the Hegelian writings. But, being a man endowed with much love of truth but with little belief in first principles, he was too wise to take for a principle Hegel’s assumption that different things are the same. He had, however, sown seeds in the minds of two distinguished pupils, T. H. Green and E. Caird, the present Master of Balliol. Both proceeded to take Hegelianism seriously, and between them spread a kind of Hegelian orthodoxy in metaphysics and in theology throughout Great Britain. Green (1836–1882) in his lectures, delivered as professor of moral philosophy at Oxford, and posthumously published under the title of *Prolegomena to Ethics* (1883), tried to effect a harmony of Kant and Hegel by proceeding from the epistemology of the former to the metaphysics of the latter. Taking for granted the Kantian hypothesis of a sense of sensations requiring synthesis by understanding, and the Kantian conclusion that Nature as known consists of phenomena united by categories as objects of experience, Green argued, in accordance with Kant’s first position, that knowledge, in order to unite the manifold of sensations by relations into related phenomena, requires unifying intelligence, or what Kant called synthetic unity of apperception, which cannot itself be sensation, because it arranges sensations; and he argued, in accordance with Kant’s second position, that therefore Nature itself as known requires unifying intelligence to constitute the relations of its phenomena, and to make it a connected world of experience. When Green said that “Nature is the system of related appearances, and related appearances are impossible apart from the action of an intelligence,” he was speaking as a pure Kantian, who could be answered only by the Aristotelian position that Nature consists of related bodies beyond appearances, and by the realistic supposition that there is a tactile sense of related bodies, of the inter-resisting members of the organism, from which reason infers similar related bodies beyond sense. But now, whatever opinion we may

have about Nature, at all events, as Green saw, it does not come into existence in the process by which this person or that begins to think. Nature is not my nature, nor your nature, but one. Everything in it is one; the sun is not lit up every time a man looks at it, as Hume would make us suppose. From this fact of the unity of Nature and of everything in Nature, combined with the two previous positions accepted, not from Nature, but from Kant, Green proceeded to argue, altogether beyond Kant, that Nature, being one, and also requiring unifying intelligence, requires one intelligence, an eternal intelligence, a single spiritual-principle, prior to, and the condition of, our individual knowledge. According to him, therefore, Nature is one system of phenomena united by relations as objects of experience, one system of related appearances, one system of one eternal intelligence which reproduces itself in us. The “true account” of the world in his own words is “that the concrete whole, which may be described indifferently as an eternal intelligence realized in the related facts of the world, or as a system of related facts rendered possible by such an intelligence, partially and gradually reproduces itself in us, communicating piecemeal, but in inseparable correlation, understanding and the facts understood, experience and the experienced world.” Nobody can mistake the Schellingian and Hegelian nature of this conclusion, which had already been imported into Great Britain by Ferrier, and which, as it became Green’s, so is now in its essence Caird’s metaphysics. It is the Hegelian view that the world is a system of absolute reason. But it is not a Kantian view; and it is necessary to correct two confusions of Kant and Hegel, which have been imported with Hegelianism by Green and Caird. Ferrier was aware that in Kant’s system “there is no common nature in all intelligence” (*Lectures*, ii. 568). Green, on the other hand, in deducing his own conclusion that the world is, or is a system of, one eternal intelligence, incautiously put it forward as “what may be called broadly the Kantian view” (*Prolegomena*, § 36), and added that he follows Kant “in maintaining that a single active conscious principle, by whatever name it be called, is necessary to constitute such a world, as the condition under which alone phenomena, *i.e.*, appearances to consciousness, can be related to each other in a single universe” (§ 38). He admitted, however, that Kant also asserted, beyond this single universe of a single principle, a world of unknowable things in themselves, which is a Kantian not a Hegelian world. But Caird has since endeavoured to break down even this second barrier between Kant and Hegel. According to Caird, Kant “reduces the inaccessible thing in itself (which he at first speaks of as affecting our sensibility) to a noumenon which is projected by reason itself” (Caird, *Essays*, ii. 405); and in the Transcendental Dialectic, which forms the last part of Kant’s *Kritik*, the noumenon becomes the object of an intuitive understanding “whose thought,” says Caird, “is one with the existence of the objects it knows” (*ib.* 412, 413). Kant, then, as interpreted by English Hegelians, already believed, before Hegel, that there is one intelligence common to all individuals, and that a noumenon is a thought of this common intelligence, “an ideal of reason”; so that Kant was trying to be a Hegelian, holding that the world has no being beyond the thoughts of one intelligence. But history repeats itself; and these same two interpretations of Kant had already been made in the lifetime of Kant by Fichte. In 1797 Fichte published two Introductions to the *Wissenschaftslehre* in his *Philosophical Journal*. In the first he said, “My system is no other than the Kantian.” In the second he admitted that the Kantians, and Kant himself, “assert the contrary,” but

contended that really the two systems are the same, and that in two respects. By the pure unity of apperception Kant meant, according to Fichte, "not the consciousness of our individuality," but "the notion of the *pure ego* exactly as the *Science of Knowledge* puts it." Secondly, by the thing in itself Kant, according to Fichte, meant a noumenon, and by a noumenon something "which arises only through our thinking." These are the very two views imputed to Kant by Green and Caird. Now, the curious fact is, that two years after Fichte had published these two interpretations, Kant himself wrote a most indignant letter, dated 7th August 1799, and published in the *Intelligenzblatt der Allgem. Literatur-Zeit.* v. J., 1799, No. 109 (*Kant's Werke*, ed. Hartenstein, viii. 600-601), on purpose to repudiate all connexion with Fichte. Fichte's *Wissenschaftslehre*, he said, is a completely untenable system, and a metaphysics of fruitless *apices*, in which he disclaimed any participation; his own *Kritik* he refused to regard as a propædeutic to be construed by the Fichtian or any other standpoint, declaring that it is to be understood according to the letter; and he went so far as to assert that his own critical philosophy is so satisfactory to the reason, theoretical and practical, as to be incapable of improvement, and for all future ages indispensable for the highest ends of humanity. After this letter, it cannot be doubted that Kant not only differed wholly from Fichte, both about the synthetic unity of apperception and about the thing in itself, but also is to be construed literally throughout. When he said that the act of consciousness, "I think," is *in allem Bewusstsein ein und dasselbe*, he meant, as the whole context shows, not that it is one in all thinkers, but only that it accompanies all my other ideas and is one and the same in all my consciousness, while it is different in different thinkers. Though again in the Transcendental Dialectic he spoke of pure reason conceiving "ideals" of noumena, he did not mean that a noumenon is nothing but a thought arising only through thinking, or projected by reason, but meant that pure reason can only conceive the "ideal," while, over and above the "ideal" of pure reason, a noumenon is a real thing, a thing in itself, which is not indeed known, but whose existence is postulated by practical reason in the three instances of God, freedom, and immortality. Consequently Kant's explanation of the unity of a thing is that there is always one thing in itself causing in us many phenomena, which as understood by us are objectively valid for all our consciousnesses. What Kant never said, and what his whole philosophy prevented his saying, was that a single thing is a single thought of a single consciousness; either of men, as in Fichte's philosophy, or of God and man, as in Hegel's. The passage from Kant to Hegel attempted by Green, and the harmony of Kant and Hegel attempted by Green and Caird, are unhistorical, and have caused much confusion of thought. The success, therefore, of the works of Green and Caird must stand or fall by their Hegelianism, which has indeed secured many adherents, partly metaphysical and partly theological. Among the former we may mention W. Wallace, the translator of most of Hegel's *Encyclopædie*, who had previously learnt Hegelianism from Ferrier; W. H. Fairbrother, who has written a faithful account of *The Philosophy of Thomas Hill Green* (1896); R. L. Nettleship, D. G. Ritchie, J. H. Muirhead, J. S. Mackenzie, and J. M. E. McTaggart, who closes his acute *Studies in Hegelian Cosmology* (1901) with "the possibility of finding, above all knowledge and volition, one all-embracing unity, which is only not true, only not good, because all truth and all goodness are but distorted shadows of its absolute perfection—'das Unbegreifliche, weil es der Begriff selbst ist.'"

There are still to be mentioned two English Hegelians,

who have not confused Kant and Hegel as Green did; namely, S. S. Laurie, who attempts to discover a new passage from Kant to Hegel, and F. H. Bradley, who builds a more independent system on the Hegelian assumption that contradictions are capable of being reconciled in a higher unity. Laurie is the author of *Metaphysica Nova et Vetusta, a Return to Dualism*, by Scotus Novanticus, 1884; 2nd edition, enlarged, 1889. His attitude to Green is expressed towards the end of his book, where he says, "The more recent argument for God, which resolves itself into the necessity of a self-distinguishing one basis to which Nature as a mere system of relations must be referred, is simply the old argument of the necessity for a First Cause dressed up in new clothes. Not by any means an argument to be despised, but stopping short of the truth through an inadequate analytic of knowledge." His aim is to remedy this defect by psychology, under the conviction that a true metaphysics is at bottom psychology, and a true psychology fundamentally metaphysics. His psychology is founded on a proposed distinction between "attuition" and reason. His theory of "attuition," by which he supposes that we become conscious of objects outside ourselves, is his "return to dualism," and is indeed so like natural realism as to suggest that, like Ferrier, he starts from Hamilton to end in Hegel. As, however, he does not suppose that we have a direct perception of something resisting the organism, such as Hamilton maintained, it becomes necessary to explain exactly what he means by "attuition." It is, according to him, something more than sensation, but less than perception; it is common to us with lower animals such as dogs; its operation consists in co-ordinating sensations into an aggregate which the subject throws back into space, and thereby has a consciousness of a total object outside itself, *e.g.*, a stone or a stick, a man or a moon. He carries its operation before reason still farther, supposing that "attuition" makes particular inferences about outside objects, and that a man, or a dog, through association "attuites" sequence and invariableness of succession, and, in fact, gets as far in the direction of causation as Hume thought it possible to go at all. Laurie's view is that "attuition," and a dog who has no higher faculty, can go no farther; but that a man goes farther by reason. He thinks that "attuition" gives us consciousness of an object, but without knowledge, and that knowledge begins with reason. His theory of reason brings him into contact with the German idealists: he accepts from Kant the hypothesis of synthesis and *à priori* categories, from Fichte the hypothesis that will is necessary to reason, from Schelling and Hegel the hypothesis of universal reason, and of an identity between the cosmic reason and the reason of man, in which he agrees also with Green and Caird. But he has a peculiar view of the powers of reason; that (1) under the law of excluded middle it states alternatives, A or B or C or D; (2) under the law of contradiction it negates B, C, D; (3) under the law of sufficient reason it says "therefore"; and (4) under the law of identity it concludes, A is A. In working out this process, he supposes that reason throws into consciousness *à priori* categories, synthetic predicates *à priori*, or, as he also calls them, "dialectic percepts." Of these the most important is cause, of which his theory, in short, is that by this *à priori* category and the process of reason we go on from sequence to consequence; first stating that an effect may be caused by several alternatives, then negating all but one, next concluding that this one as sufficient reason is cause, and finally attaining the necessity of the causal nexus by converting causality into identity, *e.g.*, instead of "Fire burns wood," putting "Fire is comburent, wood is combustible." Lastly, while he agrees

with Kant about *à priori* categories, he differs about the knowledge to be got out of them. Kant, applying them only to sensations, concluded that we can know nothing beyond by their means. But Laurie, applying them to "attentions" of objects outside, considers that, though they are "reason-born," yet they make us know the objects outside to which they are applied. This is the farthest point of his dualism; which suggests a realistic theory of knowledge, different in process from Hamilton's, but with the same result. Not so: Laurie is a Hegelian, using Kant's categories, as Hegel did, to argue that they are true not only of thoughts but of things; and for the same reason, that things and thoughts are the same. At first in his psychology he speaks of the "attention" and the rational perception of an outside object. But in his metaphysics founded thereon he interprets the outside object to mean an object outside you and me, but not self-subsistent; not outside universal reason, but only "*Beent* reason." He quotes, with approval, Schelling's phrase, "Nature is visible Intelligence and Intelligence visible Nature." He agrees with Hegel that there are two fundamental identities, the identity of all reason, and the identity of all reason and all being. Hence, he explains, what is a duality for us is only a "quasi-duality" from a universal standpoint. In fact, his dualism is not realism, but merely the distinction of subject and object within idealism. Laurie's metaphysics is an attempt to supply a psychological propædæutic to Hegelian metaphysics.

Bradley's *Appearance and Reality* (1893) is a more original performance. It proceeds on the opposite method of making metaphysics independent of psychology. "Metaphysics," says he, "has no direct interest in the origin of ideas" (254), and "we have nothing to do here with the psychological origin of the perception" (35). This metaphysical method, which we have already seen attempted by Lotze, is the true method, for we know more about things than about the beginnings of our knowledge. Bradley is right to go straight to reality, and right also to inquire for the absolute, in order to take care that his metaphysical view is comprehensive enough to be true of the world as a whole. He is unconsciously returning to the metaphysics of Aristotle in spirit; yet he differs from it *toto cælo* in the letter. Let us see first what Aristotle says. Aristotelian metaphysics is the view that reality consists of natural and supernatural substances, in the sense of distinct individuals, numerically different; and that these substances, though distinct, are variously quantified, qualified, related; that two substances being related are still different, *e.g.*; father and son, and *qua* different each *per se*, self-subsistent, independent; that a thing cannot be contradictory in the sense of being and not being something at the same time and in the same respect, *e.g.*, a square circle; but that without contradiction it can be and not be at different times, or at the same time in different respects, so that a body can change from one moment to the next in the same time, and any substance can be one as a whole and many either in its attributes or in its parts; that the same thing is capable of opposites, but is not actually both at once; that the same thing can appear sweet to one man and bitter to another at the same moment or to the same man at different moments, but not to the same man at the same moment; that finally everything is either different or the same, but not both at once. This is Aristotelianism in contrast with Bradleianism in metaphysics. The moderating genius of Aristotle introduced qualifications into metaphysical propositions in order to keep them within the truth and guard them against "sophistical difficulties." By simply omitting these qualifications, Bradley constructs his metaphysics. His starting-point is the view

that things as ordinarily understood, and (we may add) as Aristotle understood them, are self-contradictory, and are therefore not reality, but appearances. If they were really contradictory they would be non-existent. However, he illustrates their supposed contradictoriness by examples, such as one substance with many attributes, and motion from place to place in one time. But he fails to show that a substance is one and many in the same respect, and that motion requires a body to be in two places at the same moment of one time. There is no contradiction between a man being determined by many attributes, as rational, six-foot-high, white, and a father, and yet being one whole substance distinct from any other including his own son; nor is there any contradiction between his body being in bed at 8.15 and at breakfast at 8.45 within the same hour. Bradley's supposed contradictions are really mere differences. So far he reminds one of Herbart, who founded his "realistic" metaphysics on similar misunderstandings; except that, while Herbart concluded that the world consists of a number of simple "reals," each with a simple quality but unknown, Bradley concludes that reality is one absolute experience which harmonizes the supposed contradictions in an unknown manner. If his starting-point recalls Herbart, his method of arriving at the absolute recalls Spinoza. In his Table of Contents, chapter xiii., on the General Nature of Reality, he says, in true Spinozistic vein, "The Real is one substantially. Plurality of Reals is not possible." In the text he explains that, if there were a plurality of reals, they would have to be beings independent of each other, and yet, as a plurality, related to each other; and this again seems to him to be a contradiction. Throughout the rest of the work he often repeats that a thing which is related cannot be an independent thing. Now, if "independent" means "existing alone" and unrelated, the same thing could not be at once related and independent; and, taking substance as independent in that sense, Spinoza concluded that there could only be one substance. But this is not the sense in which a plurality of things would have to be independent in order to exist, or to be substances in the Aristotelian sense. "Independent" (*χωριστόν*), or "self-subsistent" (*καθ' αὐτό*) means "existing apart," *i.e.*, existing differently, as I am not you: it does not mean "existing alone," solitary, unrelated. This existing apart is the only sense in which a plurality of things need be independent in order to be real, or in order to be substances; and it is a sense in which they can all be related to each other, as I am not you, but I am addressing you. There is no contradiction, then, though Bradley supposes one, between a thing being an individual, independent, self-subsistent substance, existing apart as a distinct thing, and being also related to other things. Accordingly, the many things of this world are not self-discrepant, as Bradley says, but are distinct and relative substances, as Aristotle said. The argument, therefore, for one substance in Spinoza's *Ethics*, and for one absolute, the Real which is one substantially, in Bradley's *Appearances and Reality*, breaks down, so far as it is designed to prove that there is only one substance, or only one Real. Though the universe is one substance, one distinct thing, it includes many substances, many things distinct from, but related to, one another. Bradley, however, having satisfied himself, like Spinoza, by an abuse of the word "independent," that "the finite is self-discrepant," goes on to ask what the one Real, the absolute, is; and, as he passed from Herbart to Spinoza, so now he passes from Spinoza to Kant. Spinoza answered realistically that the one substance is both extended and thinking. Bradley answers idealistically that the one Real is one absolute experience, because all we know is experience. "This absolute," says he, "is

experience, because that is really what we mean when we predicate or speak of anything." But in order to identify the absolute with experience, he is obliged, as he before abused the word "contradictory" and the word "independent," so now to abuse the word "experience," which he takes in a far wider sense than any philosopher before him. "Experience," says he, "may mean experience only direct, or indirect also. Direct experience I understand to be confined to the given simply, to the merely felt or presented. But indirect experience includes all fact that is constructed from the basis of the 'this' and the 'mine.' It is all that is taken to exist beyond the bare moment" (248). This is to substitute "indirect experience" for all inference, and to maintain that when, starting from any "direct experience," I infer the back of the moon, which is always turned away from me, I nevertheless have experience of it; nay, that it is experience. Having thus confused contradiction and difference, independence and solitariness, experience and inference, Bradley is able to deduce finally that reality is not different substances, experienced and inferred, as Aristotle thought it, but is one absolute super-personal experience, to which the so-called plurality of things, including all bodies, all souls, and even a personal God, is appearance—an appearance, as ordinarily understood, self-contradictory, but, as appearing to one spiritual reality, somehow reconciled. But how?

(3) *Other German Influences.*—Meanwhile, but less noticeably, other English idealists, inside and outside the dominant phenomenalism of Hume, have quarried in the rich mines of German idealism. G. H. Lewes (1817–1878) was a thorough disciple of Hume's phenomenalism in his main position, that all phenomena, objective and subjective, all we perceive, all we know, things in themselves, the absolute, all are feelings, which are felt or might be felt. He saw, moreover, how Spencer has enriched empiricism "by showing that the constant experiences of the race become *organized tendencies* which are transmitted as a heritage"; and also how he has confused empiricism by supposing with Hamilton the existence, apart from all appearances, of an absolute noumenon, which, according to Spencer, is unknowable, but, according to Lewes, "metempirical," or in other words, beyond all sense, inference, and verification, an ideal construction, not of science, but of imagination. So far Lewes was an English philosopher. At the same time a sympathetic lover of literature of all kinds, he absorbed something from French and more from German sources. Affected by the positivism of Comte in his earlier days, he retained the positivist's convictions that there is no metaphysics of a world beyond phenomena, and that psychology is a branch of biology. But he was really nearer to Mill's psychological positivism, based on the method of introspection which Comte had rejected. In his later days, when he gradually elaborated his final system in *Problems of Life and Mind* (1875–79), Lewes had fallen under the spell of Kant and his successors, and produced a compromise between Hume and Kant, which reminds us of some of the later German phenomenalisms which we have already described. He agreed with Kant, as with Hume, in limiting knowledge to experience of mental phenomena of sense. He also went beyond Hume, and developed Kant's view of understanding—according to which understanding forms conceptions which must, however, be reduced to sensory intuition in experience—into a theory of inference. Inference, according to Lewes, is an ideal construction of universal conceptions symbolical of the sensible, and requiring verification by reduction to sense; it is not concluding that there are extrasensible like sensible things. Such a

theory ignores the fact that science infers not only universals but also particulars, *e.g.*, a particular eclipse, and particulars which are not always verifiable, *e.g.*, the back of the moon, a star only inferrible from a photograph, &c. But it is a theory of all the inferences which the phenomenalism of Hume could allow, or the phenomenalism of Kant when reduced to consistency. Lewes, moreover, thought that there was something even in Kant's transcendentalism; but that Kant was wrong in preferring "selbstgedachte erste Principien *à priori*" to "eingepflanzte Anlagen zum Denken," in order to vindicate a knowledge of necessity, and Spencer right in asserting inherited organized experiences. He rejected, in fact, everything in Kant's *Kritik* which savoured of the "metempirical," whether it was Kant's belief in the transcendental power of the mind to generate the *à priori*, or his belief in the transcendent existence of a noumenon. With Hegel, however, noumenalist as he was, the phenomenalist Lewes sympathized in one respect; namely, in the identification of cause and effect, except that he interpreted the hypothesis phenomenally by saying that "cause and effect are two aspects of the same phenomenon." But his main sympathy was with another noumenalist—Fechner. In the second volume of *Problems of Life and Mind*, Problem VI., on "The Absolute in the Correlations of Feeling and Motion," is simply an adaptation of Fechner's psychophysical parallelism. It begins by quoting the now celebrated passage from the *Elemente der Psychophysik*, i. 2, in which Fechner compares the spiritual and bodily sides of a man to the inner and outer sides of a circle; and it agrees with Fechner throughout that the two sides are to be identified by first regarding them as the objective and subjective aspects of one process, and then regarding that one process as only apparently bodily, but really spiritual, or, as Lewes thought in his phenomenalistic way, feeling; so that the absolute is feeling. In detail, he agreed closely with Fechner's "inner psychophysics," holding that neural process and feeling are one process viewed objectively and subjectively; that feeling is a function of the organism quantitatively varying with it; but that the neural process does not produce the feeling. "If it did," says he, "the law of the conservation of energy would be at fault, since a motion would terminate in what was neither motion nor a mode of motion." He thought that, if we identify feeling and neural process, the old mystery of the mutual action of mind and body is dispelled. He saw the difficulty, as Fechner did, that there are neural processes below and above consciousness and sensation; and he adopted Fechner's solution, that sensation is an integration of sensible units parallel to and identical with neural units or tremors, and that there are certain limits between which neural tremors are fused into neural processes and emerge in consciousness; while *beyond* these limits, on either side, there is no sensation, only sensible units. In fact, he adopted the gist of Fechner's "inner psychophysics," without, however, Fechner's noumenalistic hypothesis that what is unconscious in us is conscious in the all-embracing spirit of God. His phenomenalism also compelled him to give a more modified adhesion to Fechner's "outer psychophysics." It will be remembered that Fechner regarded every composite body as the appearance of a spirit; so that when, for example, molecular motion of air is said to cause a sensation of sound in me, it is really a spirit appearing as air which causes the sensation in my spirit. This noumenalism would not do for Lewes, who says that air is a group of qualities, and qualities are feelings, and motion is a mode of feeling. What, then, could he make of the external stimulus? He was obliged by his phenomenalism to say that it is only one feeling causing another in me. He ingeniously suggested that the external agent is one feeling regarded objectively, and the internal effect another feeling regarded

subjectively; "and therefore," to quote his own words, "to say that it is a molecular movement which produces a sensation of sound, is equivalent to saying that a sensation of sight produces a sensation of hearing." Accordingly his final conclusion is that "existence—the absolute—is known to us in feeling," and "the external changes are symbolized as motion, because that is the mode of feeling into which all others are translated when objectively considered: objective consideration being the attitude of *looking at* the phenomena, whereas subjective consideration is the attitude of any other sensible response." He does not say what happens when we use vision alone, and still infer that an external stimulus causes the internal sensation. But his metaphysics is an interesting example of a phenomenalist, sympathizing with noumenalists so different as Hegel and Fechner, and yet maintaining his phenomenalism. In this feature, in reducing Fechner's cosmic to a psychological parallelism of psychical and physical, and in supposing that all we know is feelings, in which mind and matter are opposed but not as distinct existents, while inference can make ideal constructions but without knowing anything beyond, the phenomenalism of Lewes is the English parallel to the German phenomenalism of Wundt. At the same time, and under the derivative influence of Wundt, rather than the more original inspiration of Fechner, W. K. Clifford (1845–1879) was working out the hypothesis of psychophysical parallelism to a conclusion different from that of Lewes, and more allied to that of Leibnitz the prime originator of all these hypotheses. Leibnitz had asserted that all monads have perceptions, that motions and perceptions are merely parallel, and that conscious perceptions are composed of unconscious "petites perceptions." Fechner developed this panpsychistic parallelism into an idealistic and noumenalistic identity, and gave a more mathematical form to the composition of consciousness out of units in his *Elemente der Psychophysik*, ii. 45. After the publication of this work in 1860, the hypothesis that conscious states are composed of unconscious units became common not only in Germany, but also in England and in France. We have traced its influence on Lewes. But before the publication of Lewes's *Problems, Spencer*, in discussing the Substance of Mind (*Principles of Psychology*, 2nd edition, 1870, Part II., chap. i.), had already supposed that feelings, e.g., sensations of sound, are resolvable into simpler feelings, or nervous shocks corresponding to the shocks of molecular change, that perhaps all the units of feeling are homogeneous, and that possibly units of external force may be identical with units of feeling; only that we must remember that this phenomenal analysis does not reach to the substance of noumenal matter or noumenal mind, both of which are unknowable things in themselves. Clifford broke down this artificial distinction by advancing the further hypothesis that the supposed unconscious units of feeling, or psychical atoms, are the "mind-stuff" out of which everything physical and psychical is composed, and are also things in themselves, such as Kant supposed when he threw out the hint that after all "the *Ding-an-sich* might be of the nature of mind" (see *Mind*, 1878, 67). As a matter of fact, this "mind-stuff" of Clifford is far more like the "petites perceptions" of Leibnitz, from which it is indirectly derived. Clifford first brought out this hypothesis at the Sunday Lecture Society, 1st November 1874. Both then and afterwards he connected it with the hypothesis of psychophysical parallelism. He maintained that the physical and the psychical are two orders which are parallel without interference; that the physical or objective order is merely phenomena, or groups of feelings, or "objects," while the psychical or subjective order is both a stream of feelings of which we are conscious

in ourselves, and similar streams which we infer beyond ourselves, or, as he came to call them, "ejects"; that, if we accept the doctrine of evolution at all, we must carry these ejective streams of feelings through the whole organic world and beyond it to the inorganic world, as a "quasi-mental fact"; that at bottom both orders, the physical phenomena and the psychical streams, are reducible to feelings; and that therefore there is no reason against supposing that they are made out of the same "mind-stuff," which is the thing-in-itself. The resemblance of this noumenal idealism to that of Fechner is unmistakable. The difference is that Clifford considers "mind-stuff" to be unconscious, and denies that there is any evidence of consciousness apart from a nervous system. He agrees with du Bois-Reymond in refusing to regard the universe as a vast brain animated by conscious mind. He disagrees with Fechner's hypothesis of a world-soul, the highest spirit, God, who embraces all psychophysical processes. Curiously enough, his follower G. J. Romanes (1848–1894) took the one step needed to bring Cliffordism completely back to Fechnerism. In his Rede Lecture on *Mind and Motion* (1885), he said that Clifford's deductions, that the dissolution of a human brain implies the dissolution of a human mind, and hence also that the universe, although entirely composed of mind-stuff, is itself mindless, did not follow by way of any logical sequence from his premisses. Afterwards, when the Lecture was published in *Mind and Motion and Monism* (1895), this work also contained a chapter on "The World as an Eject," in which Romanes again contended against Clifford that the world does admit of being regarded as an eject, that is, as a mind beyond one's own. At the same time, he refused to regard this "world-eject" as personal, because personality implies limitation. It seems reasonable to conclude, he says, that the integrating principle of the whole—the Spirit, as it were, of the Universe—must be something akin to, but immeasurably superior to, the "psychism" of man. Nothing can be more curious than the way in which a school of English philosophers, which originally started from Hume, the most sceptical of phenomenologists, thus gradually passed over to Leibnitz and Fechner, the originators of panpsychistic noumenalism. The Spirit of the Universe contemplated by Romanes is identical with the World-soul contemplated by Fechner.

Karl Pearson, in *The Grammar of Science* (1892, 2nd enlarged edition 1900), starting from Hume's phenomenal idealism, has developed views so like Mach's universal physical phenomenology, that it is hardly necessary to repeat here what we have already said about Mach. What Hume called repeated sequence Pearson calls "routine" of perceptions, and, like his master, holds that cause is an antecedent stage in a routine of perceptions; while he also acknowledges that his account of matter leads him very near to John Stuart Mill's definition of matter as "a permanent possibility of sensations." He copies a picture from Mach's *Beiträge zur Analyse der Empfindungen*, designed to show that one's body, so far as visible, with its environment is part of the world of sense appearing to be outside. His views, in his chapter on the Laws of Motion, that the physicist forms a conceptual model of the universe by aid of corpuscles, that these corpuscles are only symbols for the component parts of perceptual bodies, and that force is a measure of motion, and not its cause, are the views of Mach. At the end of this chapter he says that the views put forward in it were reached when the author was studying the laws of motion for teaching purposes in 1882, and were developed for the purpose of college lectures in 1884, but that the only published work in which the author has found any indication of similar opinions, or from the perusal of which he has

received any help, is Mach's *Die Mechanik in ihrer Entwicklung* (1883). In point of fact, Mach had begun to put them forward in 1872, and Kirchoff in 1874. But they may very well have been developed independently in Germany and in England from their common source in Hume. Their point is to stretch Hume's phenomenalism so as to embrace all science, by contending that mechanism is not at the bottom of phenomena, but is only the conceptual shorthand by aid of which men of science can briefly describe phenomena, and that all science is description and not explanation. These are the views of Mach and of Pearson, as we read them in the latter's Preface. Nor can we find any difference, except the minute shade that Pearson takes up a position of agnosticism between Clifford's assertion of "mind-stuff" and Mach's denial of things in themselves. J. Ward, in *Naturalism and Agnosticism* (1899), starts from the same phenomenalistic views of Mach and Kirchoff about mechanics; he proceeds to the hypothesis of duality within experience, which we have traced in the phenomenalisms of Schuppe, Avenarius, and Wundt, and to the hypothesis of one consciousness, which appears variously in the German idealisms, not of Kant, as Ward thinks, but of Fichte, Hegel, and Schuppe; and somehow he manages to end with the noumenalistic conclusion that Nature is God's Spirit. Though this work evinces a thoroughly English love of compromise, yet it is not merely eclectic, but is animated throughout by the inspiration of his "old teacher, Lotze," as Ward affectionately calls him. Lotze, as we saw, rejected bodily mechanism, reduced known bodies to phenomena, and concluded that reality is the life of God. Ward on the whole follows this triple scheme, but modifies it by new arguments founded on later German phenomenalism. Under the first head, mechanics, according to Ward, can dispense entirely with "real categories." He means, in obedience to the views of Mach and Kirchoff, that mass and force are not substance and cause; that, while mass means "mass-points," force only means mass-acceleration which is not a cause but an event; and that mechanics, requiring not causality but only dependence, is merely descriptive, or kinematical. He also identifies mass with quantity of inertia, and concludes with Leibnitz that there is passivity but no activity in the physical world. He adds that mechanics, having gradually rid itself of the categories of substance and cause, begins and ends with abstractions; that it is clear of all induction; and that the application of abstract mechanics to real bodies is throughout hypothetical, while ether is "non-matter in motion," and inconsistent with realism. "Molecules, atoms, ether, *prima materia*—one and all," says he without making any distinctions, "are hypothetical." They are even less according to him; for he holds that whatever is inferred beyond "perceptual realities" in mechanics, or any other natural science, matter and force, "mass-points" and motions, time and space, are conceptions; ideas not facts; thoughts not things; not "perceptual realities," not "phenomena," but abstract ideal conceptions devised for the description of such; and conceptions not causes. All this attack on mechanics is pure Machism, and, if consistently carried out, would have carried Ward no farther than Mach. Under the second head, according to Ward, as according to Wundt, knowledge is experience; we must start with the duality of subject and object, or perceptual reality, phenomenon, in the unity of experience, and not believe, as realists do, that either subject or object is distinct from this unity; moreover, experience requires "conation," because it is to interesting objects that the subject attends; conation is required for all synthesis, associative and intellective; thinking is doing; presentation, feeling, conation are one inseparable whole;

and the unity of the subject is due to activity and not to a substratum. But, in opposition to Wundt and in common with Schuppe, he believes that experience is (1) experience of the individual, and (2) experience of the race, which is but an extension of individual experience, and is variously called, in the course of the discussion, universal, collective, conceptual, rational experience, consciousness in general, absolute consciousness, intelligence, and even, after Caird, "a perfect intelligence." He regards this universal experience as the result entirely of intersubjective intercourse, and concludes that its subject is not numerically distinct from the subject of individual experience, but is one and continuous with it, and that its conceptions depend on the perceptions of individual experience. He infers the corollary that universal experience contains the same duality of subjective and objective factors without dualism. He thinks that it is the origin of the categories of causality, which he refers to "conation," and substance, which he attributes to the interaction of active subjects with their environment and to their intercourse with each other. He applies universal experience, as Schuppe does, to explain the unity of the object, and its independence of individual but not of universal experience, holding that the one sun, and the whole world of intersubjective intercourse, or the "trans-subjective" world, though "independent of the individual percipient as such," is "not independent of universal experience, but the object of that experience" (ii. 196-197). He applies universal experience to explain how we come, falsely in his opinion, to believe that the object of experience is an independent thing; and he uses three arguments, which are respectively those of Schuppe, Avenarius, and Wundt. He supposes first, that we falsely conclude from the sun being independent of each to being independent of all; secondly, that by "introjection" we falsely conclude that another's experience is in him and therefore one's own in oneself, while the sun remains outside; and thirdly, that by "reification" of abstractions, natural science having abstracted the object and psychology the subject, each falsely believes that its own abstract, the sun or the subject, is an independent thing. What, then, could we know from this "duality in experience"? He hardly has a formal theory of inference, but implies throughout that it only transcends perceptions, and perceptual realities or phenomena, in order to conclude with ideas, not facts. When we combine his view of Nature under the first head that whatever is inferred in the natural sciences is ideas, with his view of knowledge under the second head that knowledge is experience, and experience, individual or universal, is of duality of subject and object in the unity of experience, it follows that all we could know from the data would be one experience of the race, one subject consisting of individual subjects, and in Nature single objects in the unity of this universal experience; and beyond we should be able to form conceptions dependent on the perceptions of individual experience in the unity of universal experience: that is all. There can be no doubt that Mach, Schuppe, and Wundt drew the right phenomenalistic conclusions from such phenomenalistic data. Not so Ward, who proceeds to a Natural Theology, on the ground that "from a world of spirits to a Supreme Spirit is a possible step." He had definitely confined universal experience to the one experience of the race. But perhaps Caird's phrase "a perfect intelligence" has beguiled him into thinking that the one subject of universal experience is not mere mankind, but God Himself. Under the third head, however, his guide is Lotze. The argument may be shortly put as follows:—As the Nature which is the object of mechanics and all natural sciences, is not natural substances, but phenomena and ideas; as mass is not substance, and force is not cause; as activity is not in the

physical but in the psychical world; as the laws of Nature are not facts but teleological conceptions, and Nature is teleological, as well as not mechanical but kinematical; as the category of causality is to be referred to "conation"; as, in short, "mind is active and matter inert," what then? One subject of universal experience, one with the subjects of individual experience, you would suppose, and that Nature as a whole is its one object. Not so, according to Ward; but "God as the living unity of all," and "no longer things, but the connecting conserving acts of the one Supreme." What, then, is the relation of God to the one universal experience, the experience of the race, which was under the second head the unity in duality of all knowledge? He does not say. But instead of any longer identifying the experience of the race and universal experience, he concludes his book by saying "our reason is confronted and determined by universal reason." This is his way of destroying Naturalism and Agnosticism.

(4) *Personal Idealism*.—Mechanics does not abstract from the essentials of bodies, but only from their accidents; for, as we saw in dealing with Mach, the third law of motion was generalized by induction from the collision of bodies, which, as triply extended and mutually impenetrable substances, by their inter-resistance reduce one another to a joint mass with a common velocity so as to avoid penetration. The essential extension, inertia, and mutual impenetrability of bodies constitute the negative instance to all idealism: unless these are the attributes of Spirit, Nature is not Spirit. Again, Nature is one, but not one system of one consciousness. There is no one consciousness; the supposition of it is a confusion of same and similar. Men's minds are alike, but different. Not only do men disagree and contradict one another, but also they differ more in their minds than in their bodies. What would I not give for the mind of Aristotle or of Bacon? Moreover, men know but little of one another's minds, and that indirectly; only through their bodies, as far as we know. Consciousness is personal. I am conscious of myself, but infer everybody else. Hence it is a healthy sign that, even among the idealists, a protest is beginning to be made against the hypothesis of one mind, in favour of the personality of individuals. That this protest should arise in England against Green, Caird, and Bradley is only what might be expected. The English have long believed in individuality, in private judgment, in freedom, in the individual conscience. English moral philosophy cannot long tolerate a metaphysics which, by merging all minds in one, would destroy personality, personal causation, and moral responsibility, as J. Martineau well said. Moreover, there are signs that Green would have agreed with Martineau; for, though he resolves the whole world into one eternal intelligence, yet, however inconsistently, he wanted to make out that this absolute reproduces itself in each of us, and even in connexion with an individual animal organism. But the rise of a personal idealism is not directed merely against the English Hegelians and their master. It is also opposed to the one substance of Spinoza, the pure ego of Fichte, the absolute of Schelling in his first philosophy, and the common consciousness of Schuppe and of Ward. It is a return to the idealistic theories of personality held by Descartes, Leibnitz, Berkeley, Kant, Schelling in his later philosophy, and Fechner. Indeed, we must not suppose that recent personal idealists form one school, or that they have mastered the nature of personality, or that they have as yet worked out great systems. They are only united by their consciousness of the existence of personality.

Andrew Seth Pringle Pattison is the protagonist of the movement in his books on *Scottish Philosophy* (1885), and

Hegelianism and Personality (1887). "The radical error," says he, "both of Hegelianism and of the allied English doctrine I take to be the identification of the human and the divine self-consciousness, or to put it more broadly, the unification of consciousness in a single self"; and immediately afterwards, "Each of us is a self"; and in another passage, "The real self is one and indivisible, and is unique in each individual. This is the unequivocal testimony of consciousness." What makes his vindication of conscious personality all the more interesting is that he has so much in common with the Hegelians; agreeing as he does with Hegel that self-consciousness is the highest fact, the ultimate category of thought through which alone the universe is intelligible, and an adequate account of the great fact of existence. He agrees also that there is no object without subject. It is difficult to see exactly where he begins to differ from Hegel; but at any rate he believes in different self-conscious persons; he does not accept the dialectical method, but believes in beginning from the personal experience of one's own self-consciousness; and, though he is not very clear on the subject, he would have to admit that a thing, such as the sun, is a different object in each person's consciousness. "Every Ego," says he, "carries in itself a Non-Ego, but that does not justify us in sweeping all existence without more ado into the circle of a single self-consciousness, identifying Nature with the Non-Ego of God, and simplifying the problem by extruding our own self-consciousness altogether" (*Hegelianism*, p. 162). He is not a systematic thinker, but is too much affected by the eclectic notion of reconciling all philosophies. Thus, he thinks, on the one hand, that the Berkeleyian analysis of Mill and Bain is absolutely true as psychology, but must not pass off as metaphysics, although, if any metaphysics but idealism is true, the Berkeleyian psychology is false; and he thinks, on the other hand, that Natural Realists who believe in an intuition of the external world can accept the Hegelian metaphysics that Nature is "the other" of thought, when the former believe that the external world is perceived as body resisting the organism. F. C. S. Schiller, in *Riddles of the Sphinx* (1891), is a more systematic thinker. He rejects the difference between matter and spirit. He agrees with Leibnitz in the analysis of the material into the immaterial, but with Lotze in holding that the many immaterial elements coexist and interact. At the same time he differs from Lotze's conclusion that their union requires one absolute substance. Again, he thinks that substance is activity; differing from both Leibnitz and Lotze herein, and still more in not allowing the existence of the many beyond experience. Hence his personal or pluralistic idealism is the view that the world is a plurality of many coexisting and interacting centres of experience, while will is the most fundamental form of experience. In connexion with these views, it is a pleasure to welcome the appearance of *Personal Idealism, Philosophical Essays by Eight Members of the University of Oxford* (1902), edited by H. Sturt, and numbering Schiller, as well as G. F. Stout, H. Rashdall, and others among its contributors. They do not all agree with one another, or perhaps even with the title. Nevertheless, there is a common tendency in them, and in the University of Oxford, towards the belief that, to use the words of the editor, "We are free moral agents in a sense which cannot apply to what is merely natural." There is indeed much more activity of thought at Oxford than the world suspects. Mansel and Jowett, Green and Caird, Bradley and Bosanquet have arisen in quick succession, and in 1902 are being succeeded by a generation which is the centre of a new movement in metaphysics. We may also notice that the same sort of antithesis between the one and the many has

appeared in the United States. J. Royce is a believer in the absolute like Green and Bradley, in "the unity of a single self-consciousness, which includes both our own and all finite conscious meanings in one final eternally present insight," as he says in *The World and the Individual* (1900). G. T. Ladd also believes in "a larger all-inclusive self," and goes so far as the paradox that perfect personality is only reconcilable with one infinite being. While Royce is Hegelian, Ladd prefers Lotze, but both believe in one mind. William James, on the other hand, in his psychological works shows that the tendency of recent psychology is to personality, interpreted idealistically; though without a very clear appreciation of what a person is, and personality means. By a curious coincidence, almost at the time of the appearance of the *Essays on Personal Idealism* in England, an American writer, G. H. Hewison, published *The Limits of Evolution, and other Essays illustrating the Metaphysical Theory of Personal Idealism* (1901). But lately there has been an increase of philosophical intercourse between English and American universities, which is a hopeful sign of progress in both: they have much to learn from one another.

The advent of personal idealism is a welcome protest against the confusion of God and man in one mind, and against the confusion of one man's mind with another's. But it has not passed as yet from negative to positive philosophy. As it advances, it will carry the new school in different and unexpected directions. It will end in realism. I am conscious only of myself as a person, and of my bodily signs. I know the existence of other human persons and minds only through their giving similar bodily signs. If the personal idealist consistently denies other bodies, then the bodily signs become, according to him, only part of his experience, which can prove only the existence of himself. To infer another mind he must infer another body, and the bodily environment including his and other bodies. Again, in being conscious of myself, I am not conscious of my mind in the abstract without my body. I cannot separate touching from my tactile organs, seeing from my eyes, or hearing from my ears. I cannot think my body away. Moreover, I am not conscious of my whole personal life at all. How do I know that I was born, though I cannot remember it, and that I shall die, though I am not now conscious of death? How do I know that I am the same person from birth to death? Not by my consciousness, but by knowing the bodies of others—of babies on the one hand, and of old men on the other hand. It is usual to say that the body has not enough unity to be part of the person: the objection is much more true of conscious mind. The truth is that not the unity of consciousness but the fact of its existence is the important point. The existence of my consciousness is my evidence for my soul. But it does not prove that I am nothing but soul. As a human person, I am body and soul; and the idealistic identification of the ego with soul or mind, involving the corollary that my body belongs to the non-ego and is no part of myself, is the *reductio ad absurdum* of idealism. Lastly, though the personal idealists are right in rejecting the hypothesis of one mind, they are too hasty in supposing that the hypothesis is useless for idealistic purposes. No idealism can explain how we all know one sun, except by supposing that we all have one mind. The difficulty of personal idealism, on the other hand, is to reconcile the unity of the thing with the plurality of thinkers. The unity of the sun can only be explained either idealistically by supposing it to be one object of one mind, or realistically by supposing it to be one thing distinct from the many minds which think about it. The former alternative is false, the latter true. Personal idealism, therefore, must end in personal realism.

§ 7. REALISM.

(1) *Metaphysical and Psychological Realism.*—Realism is the view that some known things are bodily, and some are mental. At its best, it is the Aristotelian view that both are substances. The modern misunderstanding of "substance" has been a main cause of the confusion of modern thought. Aristotle meant by it any distinct thing; *e.g.*, I, you, an animal, a plant, the earth, the moon, the sun, God. He calls each of these, as existing apart, a thing *per se* (*καθ' αὐτό*). It is true that, having divided a natural substance into form and matter, he called each element "substance." But these are not primary meanings; and matter, or supposed substratum, in particular, he says, is not actually substance (*Met. Z 3*) or is only potentially substance (*Met. H 1-2*). In modern times, Spinoza, by a mere mistake, changed the meaning of "substance" from "existing apart" to "existing alone," and consistently concluded that there is only one. Locke mistook it to mean "substratum," or support of qualities, and naturally concluded that it is unknown. Kant, taking it in the mistaken meaning of Locke, converted it into the *à priori* category of the permanent substrate beneath the changes of phenomena, and even went so far as to separate it from the thing in itself, as *substantia phenomenon* from *noumenon*. When it had thus lost every vestige of its true meaning, Kant's successors naturally began to speak of things as being distinct without being substances. Fichte began this by saying that ego is activity, and being is life. Hegel said that spirit is not substance but subject, which to Aristotle would have meant that it is not a distinct thing, yet is a distinct thing. Fechner, Wundt, and Paulsen have fixed the conclusion in psychology that soul is not substance but unity of mental life; and Wundt concludes from the modern history of the term that substance or "substrate" is only a secondary conception to that of causality, and that, while there is a physical causality distinct from that of substance, psychical causality requires no substance at all. The result of this confusion is that the moderns, who think themselves a thousand times wiser than Aristotle, have no name at all for a distinct thing, and, being mere slaves of abstract terms, constantly speak of mere attributes, such as activity, life, will, actuality, unity of mental operations, as if they were distinct things. Attributes, it may be said, are knowable things, and indeed are often objects of science: thus, arithmetic deals with unity and number; geometry, with extension and figures; mechanics, with motion, force, and energy; morals, with happiness, virtue, and conscience; and politics with government and taxes. But an attribute, though real, is not a distinct reality, but is only a determinant of a substance, and has no being of its own apart from the substance so determined; whereas a substance, determined by all its attributes, is different from everything else in the world. Though, for simplicity and universality of thought, even in science, we must use the abstraction of attributes, and, by the necessity and weakness of language, must signify what are not substances by nouns substantive, we must guard against the over-abstraction of believing that a thing exists as we abstract it. A thing, as it is known to exist *in rerum natura*, is never a single attribute, *e.g.*, unity; nor a sum of attributes, *e.g.*, humanity; nor a substratum beneath these attributes in the abstract; but is always a single thing, wholly determined by all its attributes in the concrete, and different from everything else, *e.g.*, a man, a body, God. The point of true realism is Aristotle's point that the world consists of such distinct, though related, things, and therefore of substances, natural and supernatural. Again, the method of true realism is that of Aristotle, and

consists in recognizing the independence of metaphysics. The contrary method is psychological metaphysics, which makes metaphysics dependent on psychology, on the ground that the origin of knowledge determines its limits. This is the method which, as we have seen, has led from psychological to metaphysical idealism, by the argument that what we begin by perceiving is mental, and, therefore, what we end by knowing is mental. Now, there is no principle of method superior to that of Aristotle—we must begin with what is known to us. If one could begin as a child to register a history of one's own operations, one might proceed from origin to limits. But the psychologist and the metaphysician is always a grown man—too late for this process from his psychology to his metaphysics. The things best known to him are the things which he now knows as a man. About these known things there is some agreement: about the beginnings of knowledge there is nothing but controversy. We do not know enough about the origin of knowledge to determine its limits. Hence, to proceed from psychology to metaphysics is to proceed from the less to the more known; and the paradoxes of psychological have caused those of metaphysical idealism. The realist, then, ought to begin with metaphysics without psychological prejudices. He must ask what are known things, and especially what has been discovered in the sciences; in mechanics, in order to find the essence of bodies which is neglected by idealism; in mental science, in order to understand consciousness which is neglected by materialism. With the conviction that the only fair way of describing metaphysics has been to avoid putting forward one system, and even to pay most attention to the dominant idealism, we have nevertheless been driven occasionally to test opinions by this independent metaphysical method. The chief results we have found against idealism are that bodies have not been successfully analysed except into bodies, as real matter; and that bodies are known to exert reciprocal pressure in reducing one another to a joint mass with a common velocity by being mutually impenetrable, as real forces. The chief results we have found against materialism are that bodies evolving account neither for the origin of themselves, their nature, and their fundamental order of resemblance and difference, nor for the nature and origin of consciousness, nor even as yet for their becoming good for conscious beings. Hence we come to the realistic conclusions, that among known substances some are bodies, others are souls; that man is body and soul; and that God is a pure soul or spirit. At the same time, while the independence of metaphysics leads us to metaphysical realism, this is not to deny the value of psychology, still less of logic. Besides the duty of determining what we know, there is the duty of determining how we know it. But in order to discharge it, a reform of psychology as well as of metaphysics is required. Two psychological errors, among many others, constantly meet us in the history of idealism—the arbitrary hypothesis of a sense of sensations, or of ideas, and the intolerable neglect of logical inference. The latter error we have endeavoured to correct in dealing with LOGIC. Logical inference from sense is a process from sensible to insensible existence. The former error needs something deeper than a Kantian critique of reason, or an Avenarian criticism of experience; it needs a criticism of the senses. We want an answer to this question—What must we know by the senses in order to enable us to know what we infer by reason in the sciences? Without here aiming at exhaustiveness, we may bring forward against the dominant idealism a psychological theory of sense and reason. By touch, I perceive one bodily member reciprocally pressing another in myself, *e.g.*, lip press-

ing lip; by touch again, I perceive one bodily member similarly pressing but not another member in myself, *e.g.*, only one lip pressing; by inference from touch, I infer that it is reciprocally pressing another body similar to my other bodily member, *e.g.*, another body similar to my other lip. Johannes Müller recognized this sense of resistance between one's own members, and its importance for knowledge, but confused it with the inference of external resistance (see his *Elements of Physiology*, translated by Baly, p. 1081). On this theory, then, founded on the conscious facts of double and single pressure in touch, and on the logic of inference, we have at once a reason for our knowledge of external bodies, and an explanation of the early appearance of that knowledge. The child has only to have its mother's nipple in its mouth in order to infer something very like the mutually pressing parts of its own mouth. Having thus begun by touch and tactile inference, we confirm and extend our inferences of bodies in Nature by using the rest of the senses. This is not to forget that the five senses are not our whole stock, or to confine inference to body. We have also the inner sense of consciousness which is inexplicable by body alone. By combining, moreover, our knowledge of Nature with our consciousness of our own works, we can infer that Nature is a work of God. Next, finding that He gives signs of bodily works, but no signs of bodily organs, we can infer that God is a Spirit. Finally, returning to ourselves, we can conclude that, while the conscious in God is Spirit without Body, in us it is spirit with body. This final distinction between bodily and spiritual substances we owe to Descartes.

(2) *The Undercurrent of Modern Realism.*—Coming after the long domination of Aristotelian realism, Descartes and Locke, though psychological idealists, were metaphysical realists. They were what Hamilton called cosmthetic idealists and hypothetical realists. Their position was so illogical that it was easily turned into metaphysical idealism. But their psychological method and idealism produced another mistake—the tendency to a modicum of realism, as much as seemed to this or that author to follow from psychological idealism. Thus we have Spinoza and Leibnitz, and then his disciple Wolff (1679–1754), who emphasized the realistic side of Leibnitz. In Germany, since the victory of Kant over Wolff, realism has always been in difficulties, which we can appreciate when we reflect that the Germans by preference apply the term “realism” to the paradoxes of Herbart (1776–1841), who, in order to avoid supposed contradictions, supposed that bodies are not substances, but show (*Schein*), while “reals” are simple substances, each with a simple quality, and all preserving themselves against disturbance by one another, whether physically or psychologically, but not known to be either material or spiritual because we do not know the simple quality in which the nature of the real consists. There have indeed been other realisms in Germany. Trendelenburg (1802–1872), a formidable opponent of Hegel, tried to surmount Kant's transcendental idealism by supposing that motion, and therefore time, space, and the categories, though *à priori*, are common to thought and being. Dühring, with a similar object, makes matter a common basis. While these realisms come dangerously near to materialism, that of the Roman Catholic A. Günther (1783–1863), “Cartesius correctus,” erected too mystical an edifice on the psychological basis of Descartes to sustain a satisfactory realism. Yet Güntherism has produced a school, of which the most distinguished representative is the Old Catholic Bishop in Bonn, Th. Weber, whose *Metaphysik*, completed in 1891, starting from the ego and the analysis of consciousness, aims at arriving at the distinction between spirit and nature, and at rising to the spirit of God the Creator.

Another realism is that of J. H. von Kirchmann (1802–1884), author, among other works, of *Die Philosophie des Wissens* (1864), and *Ueber die Principien des Realismus* (1875). His point was that being and knowing are identical in content, and are only different in the form in which the content appears. Hence he deduced, on the one hand, that being can exist without knowing, and on the other hand that the object of perception is an image of being. Further, according to him, perception is the sole way of knowing the content, while thinking does nothing but purify the perceived content from contradictions; and therefore there are two principles of truth, (1) "Das Wahrgenommene ist," (2) "Das sich Widersprechende ist nicht." When an author thus supposes that perception knows only an image of a thing, that thinking knows no more, and that therefore knowledge is a sort of imaging of being, one cannot wonder that the idealists object that realism is a false transition from ideas to things, and speak of what they call "naive realism" with contempt. Other realisms of our time are those of G. K. Uphues, directed against the scepticism of Shute's *Discourse on Truth*, and of H. Schwarz, who completes the psychological view of Uphues that we can know objects as they are, by the metaphysical view that they can be as we know them. But German realism lacks critical power, and is little better than a weed overshadowed by the luxuriant forest of German idealism.

In France, the home of Cartesian realism, after the vicissitudes of sensationalism and materialism, which became connected in the French mind with the Revolution, the spirit of Descartes revived in the 19th century in the spiritualistic realism of Victor Cousin (1792–1867). But Cousin's psychological method of proceeding from consciousness outwards, and the emphasis laid by him on spirit in comparison with body, prevented a real revival of realism. He essayed to answer Locke by Kant, and Kant by Reid, Maine de Biran, and Schelling. From Reid, whose works had been introduced by Royer-Collard, he adopted the belief in an external world beyond sensation, from Biran the explanation of personality by will, from Schelling the identification of all reason in what he called "impersonal reason," which he supposed to be identical in God and man, to be subjective and objective, psychological and ontological. We start, according to him, from a psychological triplicity in consciousness, consisting of sensation, personal will, and impersonal reason, which by *à priori* laws of causality and substance carries us to the ontological triplicity of oneself as ego willing, the non-ego as cause of sensation, and God as the absolute cause beneath these relative causes. So far this ontological triplicity is realism. But when we examine his theory of the non-ego, and find that it resolves matter into active force and this into animated activity, identifies law with reason, and calls God absolute substance, we see at once that this spiritual realism is not very far from idealism. About 1840, owing largely to the teaching of E. Saisset in the spiritualistic school, the influence of Descartes began to give way to that of Leibnitz, whose monadism literally taken was consistent with bodies and recognized a supramundane God, but nevertheless, through its endowing monads with mental perception and appetite, could easily pass into systems of idealism and pantheism, such as we have found in Germany. Leibnitz has been used both realistically and idealistically in France. He was taken literally by spiritual realists; as, for example, by Paul Janet, whose works on Materialism (1864) and Final Causes (1876) have become well known in England by translations. Their point is that matter and evolution are inexplicable without spirit and final causes, but that, guided by "une

volonté prévoyante," evolution could be the means of rising by a continuous process from the monad to humanity. Janet accepted the traditional ontological triplicity—God, souls, and bodies—and, in answer to Ravaisson, who called this realism "demi-spiritualisme," rejoined that he was content to accept the title. At the same time, like Cousin, his works show a tendency to underrate body, tending as they do to the Leibnitzian analysis of the material into the immaterial, and to the supposition that the unity of the body is only given by the soul. His emphasis is on spirit, and he goes so far as to admit that "no spiritualist is engaged to defend the existence of matter." So E. Thouverez says, "Réalisme et rationalisme sont tout un." The strength of Janet's position is his perception that the argument from final causes is in favour of an omnipresent rational will making matter a means to ends, and not in favour of an immanent mind of Nature working out her own ends. "Beaucoup d'esprits aujourd'hui," says he at the end of *Le Matérialisme Contemporain*, "voudraient se dissimuler à eux-mêmes la pente qui les entraîne vers l'athéisme, en prêtant à la nature une vie, un instinct, une âme, et à cette âme une tendance inconsciente vers le bien." Nevertheless, the psychological metaphysics of Cousin and of Janet was too flimsy a realism to withstand its passage into this very idealism of matter which has become the dominant French metaphysics. E. Vacherot deserted Descartes for Hegel. At first in *La Métaphysique et la Science* (1858) he said, in opposition to the Cartesian argument from the perfection to the being of God, that the ideal cannot be real. But, when Janet had rejoined that "to be is worth more after all than not to be," Vacherot reconsidered his position in *Le Nouveau Spiritualisme* (1884). He accepted from Hegel "the real is rational" without the Hegelian method, for which he substituted conscious experience as a revelation of the divine. Matter he held to be mind at the minimum of its action, and evolution the "expansion de l'activité incessante de la cause finale." God, according to his latest view, is the absolute being as first cause and final end. "Let us leave," says he in deference to Janet, "the category of the ideal, which applies to nothing real or living." But the most noticeable passage in *Le Nouveau Spiritualisme* is its contrast between the old and the new; where he says that the old spiritualism opposed spirit to matter, God to Nature, the new spiritualism places matter in spirit, Nature in God (p. 377). F. Ravaisson, by his *Rapport* (prepared for the Exhibition of 1867) on philosophy in France, gave a fresh impulse to the transition from spiritual realism to idealism, by developing the Aristotelian *ἕφεσις* of matter and the Leibnitzian appetite of monads into "l'amour" as the very being of things. J. Lachelier agreed with Ravaisson that beauty is the last word of things, but, under the influence of Kant and his successors, put his idealism rather in the form that all is thought. A. Fouillée rightly objects that we must not thus impute thought and intention to nature, and yet does not scruple to impute to it life, sensation, and want. Starting from consciousness, he argues that all known things are phenomena of consciousness. Then, agreeing with evolutionism, that things are necessarily determined by forces, but with Leibnitz that body is merely passive, he infers that force, being active, is psychical—a force, which he describes as "idée-force," and as "vouloir-vivre." In connexion with the "idées directrices et organisatrices," supposed by the French physiologist Claude Bernard, and the universal will supposed by German voluntarists, Fouillée concludes that the world is a society of wills. Meanwhile, more under the influence of Kant, C. Renouvier has worked out an idealism which he calls "Néo-criticisme," rejecting

the thing-in-itself, while limiting knowledge to phenomena constituted by *à priori* categories. Phenomena he identifies with "représentations représentatives et représentées." But he takes the usual advantage of this most ambiguous of terms, when he extends it to embrace God, freedom, and immortality required by the moral law. Latterly, he has published *La Nouvelle Monadologie* (1899), in which he maintains that each monad is a simple substance, endowed with representation, which is consciousness in form, phenomenon in matter as represented. In order to explain free-will, he supposes, contrarily to Fouillée, that the laws of phenomena are indeterminate, contingent, and liable to exceptions. Here we trace the influence of Leibnitz and Lotze, which is still more marked in *La Contingence des Lois de la Nature* (1874), by E. Boutroux. Fouillée meets the mechanics of evolution by the argument that will to live determines its necessary laws, Boutroux by denying the necessity. His point is, that the world only appears to be phenomena governed by necessary laws, and is really a spontaneity which makes new beginnings, such as life and consciousness, tending to good. We wish we could have given more space to these French spiritualisms, which, realistic and idealistic alike, spring from a genuine enthusiasm for the spirit of man and his liberty. But we have said enough to show that the psychological metaphysics of spiritual realism has not been able to withstand the rise and progress of spiritual idealism in France.

In England, the land of Bacon and Locke, the realistic tendency has been more active than on the Continent, and is exhibited in Bacon's *Novum Organum* and *De Augmentis Scientiarum*, as well as to a less degree in the Fourth Book of Locke's *Essay*. After the metaphysical idealism, begun by Berkeley, had eventuated in Hume's reduction of the objects of knowledge to sensations, ideas, and associations, the Scottish School, applying the Baconian method to the study of mind, began to inquire once more for the evidences of our knowledge, and produced the natural or intuitive realism of T. Reid (1710-1796), Dugald Stewart (1753-1828), and Sir William Hamilton (1788-1856), who, having been followed by H. L. Mansel (1820-1871), as well as by J. Veitch, H. Calderwood, and J. M'Cosh, prolonged the existence of the school, in which we may venture to place L. T. Hobhouse, and F. W. Bain, author of *The Realization of the Possible* (1899), down to our own time. Its main tenet, that we have an immediate perception of the external world, is roughly expressed in the following words of Reid: "I do perceive matter objectively—that is, something which is extended and solid, which may be measured and weighed, is the immediate object of my touch and sight. And this object I take to be matter, and not an idea. And, though I have been taught by philosophers, that what I immediately touch is an idea, and not matter, yet I have never been able to discover this by the most accurate attention to my own perceptions." No opposition to idealism could be more distinct. Reid, however, did not always express himself so distinctly. Moreover, he and his successors mixed up so many accidents with the essence of their realism that the whole system broke down under its own weight. Their psychology contained valuable points. It also contained much that was doubtful, and much that was ill-adapted to the metaphysics of realism. Yet they thought it the only avenue to metaphysics. It is full of appeals to common sense, and of principles of common sense, which Reid also called intuitive first principles, and self-evident truths. It is spoiled by Locke's hypothesis that we do not perceive things but qualities implying things. While it asserted a realism of individuals, it admitted a conceptualism of universals. Stewart also said that our knowledge of matter and mind

is merely relative. Hamilton went still farther than his predecessors; he tried to combine the oil of Reid with the water of Kant; and converting the intuitive into the *à priori*, he found a further reason for the relativity of knowledge. "Our knowledge is relative," said he, "first, because existence is not cognizable absolutely and in itself, but only in special modes; second, because these modes thus relative to our faculties are presented to and known by the mind, only under modification, determined by these faculties themselves." Not only so, but in his review of Cousin ("Philosophy of the Unconditioned," in *Discussions*, pp. 12-15), he made conception the test of knowledge, argued that "the mind can conceive, and consequently can know, only the limited, and the conditionally limited," that "to think is to condition," that all we know either of mind or matter is "the phenomenal," that "we can never in our highest generalizations rise above the finite," and concluded that we cannot conceive or know the unconditioned, yet must believe in its existence. Nevertheless, in spite of all this Kantism, which ought to have driven him to the conclusion that all we know is mental phenomena, he adhered to his natural realism. He vacillated a great deal about our mode of perceiving the external world; but his final view was contained in his edition of Reid's works (note D*), and consisted in supposing that (1) sensation is an apprehension of secondary qualities purely as affections of the organism viewed as ego; (2) perception in general is an apprehension of primary qualities as relations of sensations in the organism viewed as non-ego; while (3) a special perception of a so-called "secundo-primary" quality consists in "the consciousness of a resisting something external to our organism." Hamilton's views both on the absolute and on perception affected Mansel and Spencer. They were not, however, received without question even by his followers. H. Calderwood, in his *Philosophy of the Infinite* (1854), made the pertinent objection that, though thought, conception, and knowledge are finite, the object of thought may be infinite. Hamilton, in fact, made the double mistake of limiting knowledge to what we can conceive, and confusing the determinate with the finite or limited. We never know anything except as determined by its attributes; but that would not prevent us from inferring something determined as unconditioned whether infinite or absolute. J. M'Cosh again, in *The Prevailing Types of Philosophy: Can they logically reach reality?* (1891), rightly protests against Hamilton's combination of Scottish and German schools which will not coalesce, and exhorts the former "to throw away its crutches of impressions, instincts, suggestions, and common sense, and give the mind a power of seeing things directly." He has the merit of presenting natural or intuitive realism in its purity. The common tenet of the whole school is that without inference we immediately perceive the external world, at all events as a resisting something external to our organism. But is it true? There are three reasons against it, and for the view that we perceive a sensible object within, and infer an external object without, the organism. In the first place, there are great differences between the sensible and the external object; they differ in secondary qualities in the case of all the senses; and even in the case of touch, heat felt within is different from the vibrating heat outside. Secondly, there are so-called "subjective sensations," without any external object as stimulus, most commonly in vision, but also in touch, which is liable to formication, or the feeling of creeping in the skin, and to horripilation, or the feeling of bristling in the hair; yet, even in "subjective sensations," we perceive something sensible, which, however, must be within, and not outside, the organism. Thirdly, the external world and the senses always act on one another by cause and

effect, and by pressure, although we only feel pressure by touch. Now, when the thing with which touch is in a state of reciprocal pressure is external, *e.g.*, a table, we feel our organism pressed and pressing; we do not feel the table pressing and pressed, but infer it. The Scottish School never realized that every sensation of the five senses is a perception of a sensible object in the bodily organism; and that touch is a perception, not only of single sensible pressure, but also of double sensible pressure, a perception of our bodily members sensibly pressing and pressed by one another, from which, on the recurrence of a single sensible pressure, we infer the pressure of an external thing for the first time. Intuitive Realism is to be replaced by Physical Realism.

(3) *Reaction to Hypothetical Realism.*—The three evidences, which are fatal to intuitive realism, do not prove hypothetical realism, or the hypothesis that we perceive something mental, but infer something bodily. This illogical hypothesis, which consists of incautiously passing from the truth that the sensible object perceived is not external but within the organism to the *non-sequitur* that therefore it is within the mind, derived what little plausibility it ever possessed from three prejudices: the first, the scholastic dogma that the sensible object is a *species sensibilis*, or immaterial sensible form received from the external thing; the second, the Cartesian *à priori* argument that the soul as thinking thing can perceive nothing but its own ideas; the third, the common assumption of a sense of sensations. But notwithstanding its illogicality, its tendency to underrate Nature as inferred from such idealistic premisses, and its certain transition into a consistent idealism, hypothetical realism has, with little excuse, revived among us in the writings of Shadworth Hodgson, J. Martineau, and A. J. Balfour. The cause of this anachronism has been the failure of intuitive realism and the domination of idealism, which makes short-sighted men suppose that at all events they must begin with the psychology and the psychological idealism of the day, in the false hope that on the sands of psychological idealism they may build a house of metaphysical realism.

Shadworth Hodgson, after writing many laborious works, has recently put together his conclusions in *The Metaphysics of Experience*, in four volumes, 1898. Believing that philosophy is an analysis of the contents of consciousness, or experience, and that this is metaphysics, he begins, like Kant, with an analysis of experience. Like Kant, he supposes that experience is concerned with sensations, distinguishes matter and form in sense, identifies time and space, eternal time and infinite space, with the formal element, and substitutes synthesis of sensations of touch and sight for association and inference, as the origin of our knowing such a solid material object as a bell. Although he does not agree with Kant that either the formal element in sense or the synthesis of sensations is *à priori*, yet in very Kantian fashion, through not distinguishing between operation and object, he holds that, in synthetically combining sensations of touch and sight, we not only have a complex perception of a solid body, but also know this "object thought of" as itself the complex of these sensations objectified. Hence he concludes that "*matter* is the name for the sensation-elements derived from both senses, abstracting in thought, so far as possible, from the extension-elements of both" (i. 296). Here you would expect him to stop, as the German Neo-Kantism of Lange stops, with the consistent conclusion that all we know of Nature from such data is these complexes of sensation-elements, or phenomena in the Kantian meaning. Not so; like Kant himself, Hodgson supposes something beyond; not, however, an unknown thing in itself causing sensations,

but a condition, or *sine qua non*, of their existence, without being a cause of their nature. In order to make this leap he supposes that we have beyond perceptions a conception of condition. His account of the origin of this conception is puzzling. "Although," says he, "it is neither a Kantian *à priori* concept of the understanding, nor a Scholastic intellectual intuition of causal essences, nor yet, on the other hand, a mere record of *de facto* experience, it is nevertheless an idea which is thoroughly and completely justified as true by *de facto* experience, provided that it is frankly acknowledged to be a conception which needs justification; that is to say, a conception framed by our conscious reaction on the part of the subject, whereby he interprets facts of perception, &c." (i. 380). Whatever this origin of the conception of condition may be, it could not, any more than a Kantian category of cause, justify us in concluding anything more than a relation of perceptions as conditions of one another, seeing that they were supposed to be the whole data, and matter itself to be "sensation-elements." But what he proceeds to suppose is that, having the conception, and finding that the complex of perceptions needs accounting for, we infer a real condition, *e.g.*, the solid interior of a bell. What we know, however, of this condition, according to him, has two limits: on the one hand, it is the condition only of the existence of our perceptions; on the other hand, all we know of its nature is our perceptions. Matter thus, which had at first been defined as a complex of perceptions objectified, now turns out to be a condition without which perceptions would not exist, but whose nature is known only as a complex of perceptions. Finally, according to him, having inferred matter as the condition of our perceptions, we are entitled to infer that the condition of the existence of matter is God, whose nature, however, can be inferred only by practical reason from conscience. He avers that this "metaphysic of experience" is not idealism, or the tenet that consciousness is the only reality. It is realism—but inconsequent and inadequate realism, something like that of Spencer; according, indeed, more knowledge of the distinction between nature as condition of sensations and God as condition of Nature; but very like in holding that all we know of natural forces is our perceptions. We know more, however, about a body, such as a bell, than either Spencer or Hodgson allows. We know, from the concomitant variations between its vibrations and our perceptions, that its vibrations are not mere conditions but real causes of our perceptions; and that those vibrations are not our perceptions, because we cannot perceive them, but are real attributes of the bell. It will be objected that they are merely possible perceptions. But as they really produce our real perceptions, they are themselves not merely possible, but real or actual. A possible cause could not actually produce an actual effect.

James Martineau (1805–1900) in *A Study of Religion* (1888), like Shadworth Hodgson, started from Kant, and tried to found on transcendental idealism "a return to dualism." If there is one thing certain in the Kantian philosophy, it is its author's perception that what is contributed by mind must not be extended to things beyond mind. Hegel only extended *à priori* forms to things by resolving things into thoughts. Mill also, in answer to those who would assign an *à priori* origin to the uniformity of Nature, says: "I must protest against adducing, as evidence of the truth of a fact in external nature, the disposition, however strong or however general, of the human mind to believe it." Yet Martineau following Trendelenburg, whose lectures he had attended in Germany forty years before, adopted, as his view of the limits of human intelligence, that Kant was right in making space

and time *à priori* forms of sense, but wrong in limiting them to sensations. But in order to make space a form of external things, Martineau had to take the external in space, by which Kant meant one sensation out of another, in the very different meaning of the self here and the not-self there. He facilitated this awkward transition by adding to Kant's *à priori* forms of space and time an "*à priori* form of alternative causality," or, as he also called it, "an intuition of causality involved in the elementary exercise of perception," which is the key to his whole philosophy. He supposed that this intuition of causality arises when will is resisted, and, further supposing that causality requires decision between alternatives, concluded that the intuition of will resisted is an intuition of will against will, mine against other (i. 65). To pass over its confusion of *à priori* and intuitive, there are two fatal objections to this view. In the first place, the intuition of causality does not require will at all, because we often perceive one bodily member pressing another involuntarily; a man suffering from lockjaw neither wills nor can avoid feeling the pressure of his upper and lower jaws against one another. Secondly, though causality requires alternatives in the material cause, *e.g.*, wax may or may not be melted, the determination between them is not always a decision of will, but in physical causation depends on the efficient cause, *e.g.*, the fire: as Aristotle says, when the active and passive powers approach, the one must act and the other suffer, and it is only in rational powers that will decides (*Met.* © 5). Martineau's philosophy thus falls to the ground, or rather stumbles at the start. We perceive and infer other causes than will. If allowed, however, to proceed, by combining *à priori* forms of space, time, and causality consisting of will, and holding that they are not only subjective but also objective forms, he arrives at a theory of immediate perception of the external world, involving a knowledge of both phenomena and noumena, and a dualism of ego and non-ego, reciprocally cause and effect, here and there in space, will *vis-à-vis* to will. Founded on this theory of the limits of human intelligence is his theism. If, he said, we consider cause and effect as judged by the observer of nature, we find that, while the cause of a phenomenon is always a noumenon, the relation between phenomena is, as Hume said, not a real causality. He concluded that, in order to arrive at causality, one must throw oneself into the field as agent, and then one finds antagonist agents, other wills, and ultimately the will of God. All causality then is, according to him, our will and God's will. "By *self*," says he, "we mean the will internal; by 'God' we mean the will external; by *cause* we mean either; and as the two former come into our knowledge as terms of a relation under the category of the latter, it is impossible for either extreme to lapse into the other" (ii. 176). This theory reminds us at once of the Pantheism of Schopenhauer and the Panpneumatism of Hartmann. But it is superior to both, because it recognizes intelligence in all will, without confusing either with the unconscious. Martineau also justly claimed to have freed the human will from the Pantheistic absorption which is inherent in the Panlogism of Hegel. But, with all these merits, his own theory that all causality is "will *vis-à-vis* to will" leads to strange consequences. He spoke of the will to shut a door against a furious wind. But this on his theory could only mean will to shut the door against God's will, which is fate knocking at the door with a vengeance. In his eagerness to prove the causality of God's will he had to deny all secondary causes except our wills. He said that "however wide the sweep and durable the continuance of the laws of physical change, they are entrusted with no causality of their own, but are only the modes of the

Divine action. The whole external universe then (external, I mean, to self-conscious beings), we unreservedly surrender to the In-dwelling Will, of which it is the organized expression" (ii. 176). What then becomes of Nature? Like Spencer, Martineau used the term "phenomenon" in so many varieties of sense, that we cannot attach any definite meaning to his calling Nature "the assemblage of *phenomena*, *i.e.*, of what comes and goes." But we can understand what he meant when he said that no phenomenon causes any change in any other phenomenon; he meant that no body is a cause, and that God's will and ours are the sole causes. This belittling of Nature, to magnify God and ourselves, deserts truth and defeats its own object. On the one hand, to deny that Nature is a *vera causa*, and resolve it into a sequence of phenomena, is to desert the truth that bodies are real substances and real causes by their interresistant pressure: when, for example, I try to shut the door against the wind, the wind's pressure counteracts the door's pressure directly and mine indirectly. On the other hand, to set God's will *vis-à-vis* to man's will is to make both ridiculous. God is the primary cause of all secondary causes, voluntary and involuntary; and, the greater the involuntary power of Nature, the mightier the voluntary power of the Creator and Governor of the world. *Cœli enarrant Dei gloriam.*

A. J. Balfour in *The Foundations of Belief, being Notes Introductory to the Study of Theology* (1895), begins by maintaining that the evidence of the senses is not a foundation of belief, and then expects us to believe in Nature and in God. Aristotle said that without sense there is no science, because there is no proceeding from universals without induction nor by induction without sense; and, again, that perceiving nothing we could learn and understand nothing. Bacon said, "Nos vero non Acatalepsiam sed Eucatalepsiam meditamur et proponimus: sensui enim non derogamus sed ministramus; et intellectum non contemnimus sed regimus." But Balfour has revived that very "Acatalepsia" of the New Academy. In Part II., chapter i., he makes three assumptions about the senses, and, without stopping to prove them, or even to make them consistent, deduces from them his thesis that the evidence of the senses is not a foundation of belief in Nature. He first assumes an immediate experience of a body, *e.g.*, a green tree; and then deduces that the evidence of the senses proves now and then to be fallacious, because we may have an experience indistinguishable from that of a tree but incorrect; and further, that our perceptions are habitually mendacious, because all visual experiences are erroneous, as colour is a sensation while the thing consists of uncoloured particles. This argument from a pure assumption is a confusion of sense and inference. The sense of vision perceives a sensibly visible picture, *e.g.*, green, which is always really as perceived: inference, usually rightly, though sometimes wrongly, infers a tree, and always is wrong when it infers that a tree is green like sensible green, but right when it infers that a tree is green in reflecting corresponding undulations. In no case is the evidence of the senses fallacious or mendacious; the fallacy is in the inference. He next assumes that we have no immediate experience of independent things such as has been gratuitously supposed, and by himself, but that what is immediately experienced is mental facts; or in other words, that sense perceives sensations, feelings, or ideas; while all else, *e.g.*, a tree, is a matter of inference. On this quite new assumption of a sense of sensations he deduces that, from a perception of these mental facts, we could not infer material facts, *e.g.*, a tree; so that again the evidence of the senses does not afford trustworthy knowledge of the material universe. His deduction is logical; but he has

forgotten to prove the assumption, and now confuses sensory operation with sensible object. Vision does not perceive a sensation of colour; it perceives a visible picture, e.g., green, which is in the organism, but has never been proved to be a mental fact, or not to be a material fact. So touch perceives not a sensation of pressure, but a pressure which is a material fact in the organism. From a material pressure within we logically infer a material pressure outside. He thirdly assumes an appendix to the second assumption: he assumes that sense perceives mental sensations with succession but without causality, because no kind of cause is open to observation. On this assumption of a sense of sensations but not of causality he deduces that we could not from such data infer any particular kind of cause, or a bodily cause, e.g., a tree, or indeed any cause at all, or any event beyond perception, without assuming the principle of causation that Nature is uniform in cause and effect over great intervals of time and space, assuming it without experience ready-made, and believing it beforehand. But he gives absolutely no proof of the assumption that there is no sense of causality. There is none in the subsidiary senses, because none of them perceives the pressures exerted on them. But the primary sense of touch perceives one bodily member causing pressure on another, reciprocally, within the organism, from which we infer similar particular pressures caused between the organism and the external world; but without needing the supposed stupendous belief and assumption of the uniformity of Nature, which is altogether ignored in the inferences of the ordinary man. Finally, as touch perceives reciprocal pressure within, and tactile inference infers it without, touch is the primary evidence of the senses which is the foundation and logical ground of our belief in Nature as a system of pressing bodies. Balfour, however, having from unproved assumptions denied the evidence of the senses, and the rational power of using them to infer things beyond oneself, has to look out for other, and non-rational, foundations of belief. He finds them in the needs of man. According to him, we believe in Nature because it satisfies our material needs, and in God because He satisfies our spiritual needs. But bare need, e.g., a pang of hunger, is no cause of belief beyond itself; and desire, or need of something prospective, e.g., a desire of food, is effect, not cause, of a previous belief that there is such a thing, and of a present inference that it may again be realized. Moreover, when the belief or inference is uncertain, need even in the shape of desire is not in itself a foundation of belief in the thing desired: to need a dinner is not to believe in getting it; and, as Aristotle said, "there is a wish for impossibilities." It is fair, however, to add that Balfour has a further foundation for the belief in Nature, the survival of the fittest, by which those only would survive who possessed and could transmit the belief. But here he fails exactly as Darwin himself failed. Darwin said, given that organisms are fit, they will tend to survive; but he failed to show how they become fit. Balfour says, given that men believe in Nature, they will survive; but he fails to show how they come to believe in it. Inference from sense is the one condition of all belief in anything beyond oneself, whether it be Nature, or Authority, or God; and it is the one condition of all needs, which are not mere feelings, but desires of things. The result of undermining this sure foundation emerges in Balfour's attitude to the beliefs themselves. He holds that space, time, matter, motion, force, are all full of the insoluble contradictions supposed by Spencer; and that all our beliefs, in Nature and in God, stand on the same footing of approximations. Hence his really valuable arguments from Nature to God sink to the problematic form—there

may be Nature; if so, there is God. Such is the modern "Acatalepsia," which arises from denying the evidence of the senses, and from citing the transfigured realism of Spencer instead of the original realism of Aristotle, about whom Balfour speaks as follows: "It would be difficult, perhaps impossible, to sum up our debts to Aristotle. But assuredly they do not include a tenable theory of the universe."

(4) *The Past and Future of Metaphysics.*—Aristotelian realism is the strong point of Roman Catholic philosophy. As interpreted by Thomas Aquinas, it is now in danger of becoming a dogma. In 1879 Pope Leo XIII. addressed to the bishops the *Encyclica Æterni Patris*, which contained the words, *Sancti Thomæ sapientiam restituatis et quam latissime propagetis*. From the Roman Catholic point of view, this reaction to "Thomism" was a timely protest against modern metaphysics. It was founded upon a feeling of uneasiness at a growing tendency among Roman Catholic writers not only to treat theology freely, but to corrupt it by paradoxes. Thus the French philosophy of Cousin was suspected by the Vatican of pantheism; the German philosophy of Günther, "Cartesius correctus," was condemned at Rome in 1857; and in 1888 the Italian philosophy of Rosmini, which leaned towards German idealism, was condemned by Leo XIII. himself. The Jesuits regarded modern philosophy as the pathology of human reason, and they were at the bottom of the movement. Perhaps they were not altogether mistaken. One cannot but feel regret at seeing the Reformed Churches blown about by every wind of doctrine, and catching at straws now from Kant, now from Hegel, and now from Lotze, or at home from Green, Caird, Martineau, Balfour, and Ward in succession, without ever having considered the basis of their faith; while the Roman Catholics are making every effort to ground a Universal Church on a sane system of metaphysics. However this may be, the power of the movement is visible enough from the spread of Thomism over the civilized world, and in England from the difference between the freer treatment of metaphysics by some of our Roman Catholic writers and that which has arisen under the immediate influence of Thomism. J. H. Newman (1801–1890), maintaining the authority of conscience and the probabilism of the understanding, concluded to the necessity of a higher authority in the primitive Church. W. G. Ward was a philosophical critic of Mill. St George Mivart, in *The Ground-work of Science* (1898), maintained the reality of an active causative power underlying Nature, and the dignity of human reason, from an independent point of view. On the other hand, more under the influence of the Thomist reaction Thomas Harper has published *The Metaphysics of the School* (1879, &c.), describing scholasticism, as it appears in the works of Aquinas; and *The Manuals of Catholic Philosophy*, edited by R. F. Clarke, include *General Metaphysics* (1890), by J. Rickaby, who effectively criticizes Hegel by precise distinctions, which, though scholastic, did not deserve to be forgotten.

The Thomist reaction has had a good effect in the way of encouraging the study of Aristotelian philosophy, in itself and as modified by Aquinas. Nevertheless, the world cannot afford to surrender itself to Aristotle, or to Aquinas; the master had too many weak points, and the commentator has corrected too few of them. Aristotle could not know enough, physically, about Nature to understand its matter, or its motions, or its forces; and consequently he fell into the error of supposing a primary matter with four contrary primary qualities, hot and cold, dry and moist, forming by their combinations four simple bodies, earth, water, air, and fire, with natural rectilineal motions to or from the centre of the earth; to

which he added a quintessence of ether composing the stars, with a natural circular motion round the earth. Metaphysically, he did not, indeed, as is often supposed, think the nature of substance to be matter and form, because in his view God is a substance, yet with no matter; but he did think that every natural substance, or body, is a concrete whole, composed of matter and form different from matter. He thought that besides proximate matter, or one body as matter of another, there is a primary formless matter beneath all bodies, capable of becoming all in turn, but itself potentially, not actually, substance. He thought not only that a form, or essence, is something different from, and at most conjoined with, matter in a concrete body, but also that in all the bodies of one kind, *e.g.*, in all men, there is one undivided form or essence, *e.g.*, rational animal, communicated from one member to another member of the kind, *e.g.*, from father to son, by what we still call, though without any meaning, the propagation of the species. He thought, in consequence, that the *principium individuationis*, which differentiates two members of the kind, *e.g.*, Socrates and Callias, is their one form or essence only as conjoined with different matters, *e.g.*, different bones and flesh. He thought, moreover, that the one form of a kind is an original essence (τὸ τί ἦν εἶναι), which is uncreate; and, in order to avoid the "separate forms" supposed by Plato, he concluded that the world of Nature must be eternal, in order that each original essence may from eternity always be in some individual or another of its kind. On this assumption of the eternity of the world, God could not be a Creator. Aristotle thought that God is only prime mover, and that too only as the good for the sake of which Nature moves; so that God moves as motive. Psychologically, Aristotle applied his dualism of matter and form to explain the antithesis of body and soul, so that the soul is the form, or entelechy, of an organic body; and he applied the same dualism to explain sensation, which he supposed to be reception of the sensible form or essence, without the matter, of a body, *e.g.*, of the form of white, without the matter, of a white stone. He thought that in the soul (ἐν τῇ ψυχῇ) there is a productive intellect and a passive intellect, and that, when we rise from sense by induction, the productive causes the passive intellect to receive the universal form or essence, *e.g.*, of all white things; and he thought that this productive intellect is our immortal faculty. Lastly, he thought that, while other operations have, intellect (νοῦς) has not, a bodily organ; and hence he became responsible for the fancy that there is a break in bodily continuity between sense and will, while intellect is working out a purely immaterial operation of soul, resulting from the former and tending to the latter. It is evident that a philosophy containing so many questionable opinions is not fit to be made into an authoritative orthodoxy in metaphysics.

Now these, on the whole, are the very opinions of Aquinas (1225-1274), except so far as they were clearly inconsistent with the Christian faith. Aquinas thought, as an article of faith, that the world began, and that God is its Creator. This Christian difference from Aristotle involved a change of detail in the theory of essences and of universals generally. Aquinas thought that before the creation the one eternal essence of any kind was an abstract form, an idea in the intellect of God, like the form of a house in the mind of a builder, *ante rem*; that after the creation of any kind it is *in re*, as Aristotle supposed; and that, as we men think of it, it is *post rem*, as Aristotle also supposed. Of this view the part which was not Aristotle's, the state of "universalia ante rem," was due to the Neo-Platonists, who interpreted the "separate forms" of Plato to be ideas in intellect, and handed down their interpretation through St Augustine to the mediæval

Realists like Aquinas, who thus combined Neo-Platonism with Aristotelianism. Hence too Aquinas opposed essence to existence much more than Aristotle did. Lastly, as a Christian, he supposed the whole soul to be immortal, and to form for itself a new body after death. But, with these modifications he accepted the general physics of Aristotle, the metaphysical dualism of matter and form, and the psychology founded upon it. The Thomism, therefore, of our day is wrong, from a metaphysical point of view, so far as it elevates Aristotelianism, as seriously modified but not fundamentally corrected by Aquinas, into an authoritative orthodoxy in metaphysics.

Centuries elapsed after Aquinas before Galileo and his successors reformed natural science, and before Bacon destroyed the metaphysical dualism of matter and form by showing that a form in Nature is only a law of the action of matter, and that, as the action of a body is as individual as the body, the form is eternal only in thought (*ratione*). The psychology of Aristotle and Aquinas thus became impossible; for, if the form of a body is only a mode of matter, to call one's soul the form of one's body is to reduce it to only a mode of matter, and fall into materialism. Hence Descartes began the reform of psychology not only by the appeal to consciousness, "I think," but also by opposing body and soul, no longer as matter and form, but as different substances. These great improvements, due to the genius of Galileo, of Bacon, of Descartes, are the fresh beginnings of modern thought, from which we dare not turn back without falling into obscurantism. What, then, is the future of metaphysics? We must return not to the authority but to the study of Aristotle. The independence of metaphysics as the science of being, the principles of contradiction and excluded middle with their qualifications, the distinction without separation between substance and attributes, the definition of substance as a distinct individual thing, the discovery that the world consists of substances existing apart but related to one another, the distinction between material and efficient causes or matter and force, the recognition both of the natural and of the supernatural—all these and many other half-forgotten truths are the reasons why we must always begin with the study of Aristotle's *Metaphysics*. But their incompleteness shows that we must go forward from Aristotle to Bacon and modern science, and even pass through the anarchy of modern metaphysics, in the hope that in the future we may discover as complete an answer as possible to these two questions:—

1. What is the world of things we know?
2. How do we know it?

Meteor.—Meteors, or shooting stars, as they are familiarly called, are minute bodies which, moving through space, are raised to incandescence by encountering the atmosphere of the earth. Great swarms of these bodies move in streams along common orbits. The outburst of several meteors belonging to the same stream is called a shower, and every shower has a radiant point from which the paths of all its meteors are directed. During the last quarter of the 19th century a large number of radiant points of meteoric showers have been made out. The number of such points known in 1876 was 850, whereas in 1899 it had risen to 4400, but they do not all represent different systems. The great majority of meteoric streams are very feeble, but the displays arising from a few recur at intervals with brilliant effect. The following is a list of the dates and radiants of some of the principal showers:—

Date	Radiant R. A. Dec.	Date	Radiant R. A. Dec.
Jan. 2-3	230°+53°	Aug. 30-Sept. 2	47°+43°
Feb. 10-15	74 +43	Sept. 10-15	62 +37
March 1	166 + 5	Sept. 21-22	74 +41
March 28	263 +62	Oct. 2	230 +52
April 19-22	270 +33	Oct. 18-20	92 +15
May 2-6	338 - 2	Oct. 29-Nov. 1	43 +22
May 11-18	231 +27	Nov. 2	55 + 9
May 30	333 +27	Nov. 14-16	151 +22
June 3-7	250 -22	Nov. 20-23	63 +22
July 15-19	314 +48	Nov. 23-24	25 +44
July 28-30	339 -12	Nov. 25	154 +40
Aug. 10-12	45 +57	Dec. 6	80 +23
Aug. 12-15	292 +53	Dec. 10-12	108 +33
Aug. 21-23	291 +60	Dec. 12	119 +29

The August shower of Perseids is annually visible for several weeks (July 11 to August 20), the radiant having a daily motion of 1° to the E.N.E. The October Orionids are to be seen during three weeks from a fixed radiant. Some showers appear to be of short duration, while others continue for several weeks, if not months. Probably more than 100 meteor showers of very feeble character are in action on every night of the year. The Lyrids (April 19-22), Leonids (November 14-16), and Andromedids (November 23-24) are periodical, and sometimes make brilliant displays. The Quadrantids (January 2-3), Perseids (maximum, August 10-12), Orionids (October 18-20), Geminids (December 10-12), and other systems recur annually without any great variation of strength. Bright returns of the Leonids will probably be witnessed in November 1933, 1934, 1966, &c. The Andromedids should reappear in November 1905, in 1912-13, and 1918-19.

In the spectroscope most bright meteors show the green line of magnesium as a principal constituent. In a large meteor of 26th July 1873, Professor Konkoly remarked the lines of magnesium and sodium. Other lines in the red and green have been seen, and found by comparison identical with the lines of marsh gas. Bright meteors often emit the bluish white light suggestive of burning magnesium. In addition to magnesium and sodium, the lines of potassium, lithium, and also the carbon flutings exhibited in cometary spectra have been seen.

The movements of those meteorites which have actually been seen to fall upon the earth have been investigated by Professor Newton with a view to ascertaining the character of their orbits. In the great majority of cases he found that they had moved in direct orbits, inclined

less than 90°, and that their perihelion distances were between 0.5 and 1.0, the earth's distance from the sun being unity. His opinion was therefore that the large meteorites moving in our solar system are allied much more closely with the group of short-period comets than with parabolic comets. This is true also of the large, slow-moving fireballs which are consumed in our atmosphere and do not reach the ground. The writer, comparing a large number of observations of these objects which appeared during the 19th century, finds that the majority travelled slowly from radiant points near the horizon, and from directions in which they must necessarily have overtaken the earth in her orbit. This suggests a community of origin between stony meteorites which have been seen to fall, fireballs which are burnt up and dissipated in the air, and comets of short period.

Meteoritic observation has depended upon rough and hurried eye-estimates in past years, but the importance of ensuring greater accuracy by means of photography has recently been recognized. At Yale, Harvard, and Northfield observatories and at Vienna, photographic determinations were made of the radiant of the inconspicuous Leonid meteor-shower of 1898. They give a mean of R. A. 151° 33', Dec. +22° 12'. This is probably much more correct than the average place of 109 various eye-determinations of the same radiant, which put it at R. A. 149° 40', Dec. +22° 42'. In 1899 elaborate preparations were made in various places to observe the shower and to obtain photographic trails of as many meteors as possible, but the expected display failed to assume a striking character, and the photographic method resulted in practical failure. Calculations indicate that the group of meteors has been disturbed by the powerful attraction of Jupiter and Saturn, and that probably the swarm passed more than a million of miles inside the earth's orbit instead of nearly intersecting it as formerly. But as we do not know the exact width of the stream or the amount of the perturbations it has suffered, the display may yet recur with some of its former brilliancy.

About 1866 the orbit elements of four well-observed comets were found to present a great affinity to, if not actual identity with, the orbits of four of the best-known and most brilliant meteoric streams. More recent years have added few, if any, well-defined correspondences of similar character, though the orbit of a shower of Aquarids, occurring early in May, offers a suggestive resemblance to the path of Halley's comet. It may be thought surprising, when the large number of cometary and meteoric systems are considered, that so few accordanances have been detected, but the explanation is that really very few comets pass near enough to the earth to give rise to showers of meteors. Of eighty comets observed during the twenty years ending 1893, Professor Herschel found that only two, viz., Denning's comet of 1881 and Finlay's of 1886, approached comparatively near to the earth's path, the former within 3,000,000 miles and the latter to within 4,600,000. (See COMETS.)

METEOROLOGY.

PROPERLY speaking, meteorology is the study of all the phenomena of the gaseous atmosphere that surrounds the earth and extends to some unknown outer surface that marks the beginning of the so-called interstellar space. These phenomena may be studied either individually or collectively. The collective study has to do with statistics and general average conditions, sometimes called normal values, and is known as *Climatology*. The study of the individual items may be either descriptive, explanatory, physical, or theoretical. Physical meteorology is again subdivided according as we consider either the changes that depend upon the motions of masses of air or those that depend upon the motions of the gaseous molecules; the former belong to hydrodynamics, and the latter are mostly comprised under thermodynamics, optics, and electricities.

The general problems of climatology are best presented in the *Lehrbuch* of Dr Julius Hann (second edition, Strasburg, 1896). The general distribution of temperature, winds, and pressure over the whole globe was first given by Buchan in charts published by the Royal Society of Edinburgh in 1868, and again greatly revised and improved in the volume of the *Challenger* reports devoted to meteorology. The most complete atlas of meteorology is Buchan and Herbertson's edition of Bartholomew's *Atlas*, published in London in 1899. Extensive works of a more general character have been published by the London Meteorological Office, and the Deutsche Seewarte for the Atlantic, Pacific, and Indian Oceans. Daily charts of atmospheric conditions of the whole northern hemisphere were published by the U.S. Weather Bureau from 1875 to 1883 inclusive, with monthly charts for succeeding years. The physical problems of meteorology were discussed in Ferrel's *Recent Advances in Meteorology*, Washington, 1885. Mathematical papers on this subject will be found in the author's collection known as *The Mechanics of the Earth's Atmosphere*, second edition, Washington, 1893; the memoirs by Helmholtz and Von Bezold contained in this collection have been made the basis of a most important work by Brillouin, Paris, 1898, entitled *Vents Contigus et Nuages*. A general summary of our knowledge of the mechanics and physics of the atmosphere is contained in the Report on the International Cloud Work by F. H. Bigelow, Washington, 1900. The extensive treatise on meteorology by Dr Julius Hann (1901) is an authoritative work. The optical phenomena of the atmosphere are well treated by Mascart in his *Traité d'Optique*, Paris, 1891-98. Of minor treatises especially adapted to popular reading, or to school use, or collegiate courses of study, we may mention those by Sprung, Berlin, 1885; Ferrel, New York, 1890; Angot, Paris, 1898; Davis, Boston, 1893; Waldo, New York, 1898; Van Bebber, Stuttgart, 1890; Moore, London, 1893; Russell, New York, 1895.

I. FUNDAMENTAL PHYSICAL DATA.

Atmospheric air is a mixture of nitrogen, oxygen, aqueous vapour, carbonic acid gas, ammonia, argon, neon, helium, and possibly traces of free hydrogen and hydrocarbons. The proportions in which these gases are present are quite constant, except that the percentage of aqueous vapour is subject to large variations. In an atmosphere that is saturated at the temperature of 90° F., as may occur in such a climate as that of Calcutta, the water may be $2\frac{1}{2}$ per cent. of the whole weight of any given volume of air. When this aqueous vapour is entirely abstracted, the remaining dry gas is found to have a very uniform constitution in all regions and at all altitudes where examination has been carried out. In the so-called dry atmosphere the relative weights are about as follows:—Oxygen, 23.16; nitrogen and argon, 76.77; carbonic acid, 0.04; ammonia and all other gases, less than 0.01 in the lower half of the atmosphere, but probably in larger percentages at great altitudes. The two constituents, argon and neon, were discovered by Rayleigh and Ramsay in January, 1895; in 1898 Ramsay and Travers announced the presence of krypton. The density of argon is about 19.9, that of oxygen 16, and

that of nitrogen 14, when hydrogen is unity. Dewar has so perfected the process of reaching low temperatures that liquid hydrogen has been produced, and by its means all the more easily condensed gases contained in atmospheric air have been removed, so that there is left in the experimental tube a minute quantity of less condensable gases, such as helium. These exceedingly volatile components of the atmosphere cannot apparently be held down to the earth by the attraction of gravitation, but are continually diffusing through the atmosphere outwards into interstellar space, and possibly also from that region back into the atmosphere. There are doubtless other volatile gases filling interstellar space and occasionally entering into the atmosphere of the various planets as well as of the sun itself; even the hydrogen and hydrocarbons that escape from the earth into the lower atmosphere undoubtedly ascend to regions inaccessible to man and slowly diffuse into the outer space. The laws of diffusion show that for each gas there is an altitude at which as many molecules diffuse inwards as outwards in a unit of time. This condition defines the outer limit of each particular gaseous atmosphere, so that we must not imagine the atmosphere of the earth to have any general boundary. The only intimation we have as to the presence of gases far above the surface of the globe comes from the phenomena of the refraction of starlight, the morning and evening twilight, and especially from the shooting stars which suddenly become luminous when they pass into what we call our atmosphere. Such observations are supposed to show that there is an appreciable quantity of gas at the height of one hundred miles, where it may have a density of a millionth part of that which prevails at the earth's surface.

According to Professor E. W. Morley, of Cleveland, Ohio, the relative proportions of oxygen and nitrogen vary slightly at the surface of the earth according as the areas of high pressure and low pressure alternately pass over the point of observation; his remarkably exact work seems to show a possible variation of a small fraction of 1 per cent., and he suggests that the air descending within the areas of high pressure is probably slightly poorer in oxygen. The proportion of carbonic acid gas varies appreciably with the exposure of the region to the wind, increasing in proportion to the amount of the shelter; it is greater over the land than over the sea, and it also slightly increases by night-time as compared with day, and in the summer and winter as compared with the spring and autumn months. During the year 1896 Professor Arrhenius in the *L. E. D. Philosophical Magazine*, and in 1899 Professor Chamberlin in the *American Geological Journal*, published memoirs in which they argue that a variation of several per cent. in the proportion of carbonic acid gas is quite consistent with the existence of animal and vegetable life, and plausibly explains the cold climate of any glacial period. The question whether free ozone exists in the atmosphere is still debated, but there seems to be no satisfactory evidence of its presence, except possibly for a few minutes in the neighbourhood of, and immediately after, a discharge of lightning. In the case of still air the general proportions of the principal gases up to considerable altitudes can be calculated with close approximation by the laws of diffusion and elastic pressure; on the other hand, actual observations show that the rapid convection going on in the atmosphere changes these proportions and brings about a fairly uniform percentage of oxygen, nitrogen, and carbonic acid gas up to a height of ten miles. The quantity of aqueous vapour is controlled by temperature quite as much as by

convection, and has very little to do with diffusion; the law of its distribution in altitude has been well expressed by Hann by the simple formula: $\log e = \log e_0 - h/6517$ where h is the height expressed in metres and e and e_0 are the vapour tensions at the upper station and sea-level respectively. Thus, if the vapour tension is 10 millimetres at sea-level corresponding to saturation at a temperature of about 11° C. or 52° F., then the pressure and the dew-point at other altitudes should be about as follows:—

Altitude.	Vapour Pressure.	Dew-Point.
Kil.	Mm.	° C.
0	10·00	+11·4
5	6·87	+ 5·8
10	4·59	+ 0·1
15	2·98	— 5·0
20	1·86	—10·6
30	0·64	—22·0
40	0·18	—34·2
50	0·04	—48·0
60	0·00	?

In addition to the gases and vapours in the atmosphere, both meteorology and hygiene have come to consider the motes of dust as very important constituents. The aqueous particles that constitute cloud, fog, and haze are also important. As all these float in the air, slowly descending, but resisted by the viscosity of the atmosphere, their whole weight is added to the atmosphere and becomes a part of the barometric record. When the air is cooled to the dew-point and condensation of the vapour begins, it takes place first upon the atoms of dust as nuclei; consequently, air that is free from dust is scarcely to be found except within a mass of cloud or fog.

According to a calculation published in the *U.S. Monthly Weather Review* for February 1899, the total mass of the atmosphere is 1/1,125,000 of the mass of the earth itself, but, according to Professor R. S. Woodward (see *Science* for January 1900), celestial dynamics shows that there may possibly be a gaseous envelope whose weight is not felt at the earth's surface, since it is held in dynamic equilibrium above the atmosphere; the mass of this outer atmosphere cannot exceed $\frac{1}{1200}$ th of the mass of the earth, and is probably far less, if indeed it be at all appreciable.

There can be no proper study of meteorology without a consideration of the various physical properties of the atmosphere's gases and vapours, each of which plays an independent part, and yet also reacts upon its neighbours.

Physical properties.
Conductivity.—Dry air is a poor conductor of heat, its coefficient of conduction being expressed by the formula: $0\cdot000\ 0568 (1+0\cdot00190t)$ where the temperature (t) is expressed in centigrade degrees. This formula states the fact that a plate of air 1 centimetre thick can conduct through its substance for every square centimetre of its area, in one second of time, when the difference of temperature between two faces of the plate is 1° C., enough heat to warm 1 gram of water $0\cdot000\ 0568$ ° C., or 1 gram of air $0\cdot000\ 239$ ° C., or a cubic centimetre of air $0\cdot1850$ ° C., if that air is at the standard density for 760 millimetres of pressure and 0 degrees of temperature centigrade.

Diathermancy.—The air is extremely diathermanous or transparent to the general transmission of radiant heat. In general the coefficient of transmission increases as the heat waves become longer, but certain wave-lengths or kinds of heat are specifically absorbed. The general coefficient of transmission for a zenithal sun is 0·4 at the violet and 0·8 at the red end of the spectrum. By the specific absorption certain long wave-lengths are entirely cut off by aqueous vapour and others by the carbonic acid gas, so that in general the atmosphere appears to be more

transparent to the short wave-lengths. When the zenithal sun's rays fall upon a station whose barometric pressure is 760 millimetres, then only from 50 to 80 per cent. of the total heat reaches the earth's surface, and thus the general coefficient of transmission for the thickness of one atmosphere is usually estimated at about 60 per cent. Of course when the rays are more oblique, or when haze, dust, or cloud interfere, the transmission is still further diminished. In general one-half of the heat received by the illuminated atmosphere is absorbed by it, leaving the other half to reach the surface of the ground, provided there be no intercepting clouds. The thermal conditions actually observed at the immediate surface of the globe may therefore be of minor importance in the mechanism of the atmosphere.

Specific Heat.—The capacity of the air for heat varies according as the heat increases the volume of the air expanding under constant pressure, or the pressure of the air confined in constant volume. The specific heat under constant pressure is about 1·406 times the specific heat under constant volume. The numerical value of the specific heat under constant pressure is about 0·2377; that is to say, that number of calories, or units of heat, is required to change the temperature of 1 gram of air by 1° C. This coefficient holds good, strictly speaking, between the temperatures minus 30° and plus 10° C., and there is a very slight diminution for higher temperatures up to 200°.

Radiating Power.—The radiating power of dry air is so small that it cannot be measured quantitatively, but the spectroscopist and bolometer demonstrate its existence. The coefficient of radiation of the moisture diffused in the atmosphere is undoubtedly much larger than that of the particles of dust and cloud, and is nearly equal to that of a lamp-black surface, or unity. From the normal diurnal change in temperature at high and low stations, it should be possible to determine the general coefficient of atmospheric radiation for the average condition of the air in so far as this is not obscured by the influence of the winds. This was first done by Maurer in 1885, who obtained a result in calories that may be expressed as follows:—The total radiation in twenty-four hours of a unit mass of average dusty and moist air towards an enclosure whose temperature is 1° lower is sufficient to lower the temperature of the radiating air by 3·31° C. in twenty-four hours. This very small quantity was confirmed by the studies of Trabert, published in 1892. The direct observations of Hutchins on dry dusty air, as published in 1890, gave a much larger value—evidently too large. The investigation of this subject prosecuted by Professor F. W. Very at the Allegheny Observatory, and published as "Bulletin G" of the U.S. Weather Bureau, shows the character and amount of the radiation of several gases, and especially the details of the process going on under normal conditions in the atmosphere.

Density.—The absolute density or weight of a cubic centimetre of dry air at the standard pressure, 760 millimetres, and temperature 0° C., is 0·001 29305 grams; that of a cubic metre is 1·29305 kilograms; that of a cubic foot is 0·08071 pounds avoirdupois.

Expansion.—The air expands with heat, and the expansion of aqueous vapour is so nearly the same as that of dry air that the same coefficient may be used for the complex atmosphere itself as a whole. The change of volume may be expressed in centigrade degrees by the formula $V = V_0 (1 + 0\cdot000\ 3665t)$, or in Fahrenheit degrees $V = V_0 (1 + 0\cdot000\ 237t)$.

Elasticity.—The air is compressed nearly in proportion to the pressure that confines it. The pressure, temperature, and volume of a true gas are connected by the

equation $pv=RT$, where T is the absolute temperature or 273° plus the centigrade temperature; p is the barometric pressure in millimetres and v the volume of a unit mass of gas, or the reciprocal of the density of the gas. The constant R is 29.272 when the centimetre, the gram, the second, and the centigrade degrees are adopted as units of measure, and differs for each gas. The number just given relates to dry atmospheric air. For aqueous vapour in a gaseous state and not near the point of condensation R has the value 47.061. For ordinary air in which x is the mass of the aqueous vapour that is mixed with the unit mass of dry air, the above equation becomes $pv=(29.272+x47.061)T$. This equation is sometimes known as the equation of condition peculiar to the gaseous state. It may also be properly called the equation of elasticity or the elastic equation for gases, as expressing the fact that the elastic pressure p depends upon the temperature and the volume. The more exact equation demonstrated by

Van der Waals, *i.e.*, $\left(p + \frac{a}{v^2}\right)(v-b)=RT$, is not needed for the low pressures that occur in meteorology.

Diffusion.—In comparison with the winds, it may be said that it is difficult for aqueous vapour to diffuse in the air. In fact, the distribution of moisture is carried on principally by the horizontal convection due to the wind and the vertical convection due to ascending and descending currents. Diffusion proper, however, comes into play in the first moments of the process of evaporation. The coefficient of diffusion for aqueous vapour from a pure water surface into the atmosphere is 0.18 according to Stefan, or 0.1980 according to Winkelmann; that is to say, for a unit surface of one square centimetre, and a unit gradient of vapour pressure of one atmosphere per centimetre, as we proceed from the water surface into the still dry air, at the standard pressure and temperature, the quantity of moisture diffused is 0.1980 gram per second. This coefficient rises or increases with the temperature, and is 0.2827 at 49.5° C. But this rate of diffusion diminishes very rapidly at a small distance from the free surface of the water, so that the most important condition facilitating evaporation is the action of the wind.

Viscosity.—When the atmosphere is in motion each layer is a drag upon the adjacent one that moves a little faster than it does. This drag is the so-called molecular or internal friction or viscosity. The coefficient of viscosity in gases increases nearly in proportion to the absolute temperature, and its value is given by an equation like the following: $0.000\ 248 (1+0.003\ 665t)^{\frac{2}{3}}$, which is the value given by Carl Barus (*Ann. Phys.* 1889, xxxvi.). This expression implies that for air whose temperature is the absolute zero there is no viscosity, but that at a temperature of 0° C., or 273° on the absolute scale, a force of 0.000 248 gram is required in order to push or pull a layer of air 1 centimetre square past another layer distant from it by 1 centimetre at a uniform rate of 1 centimetre per second. In treating of the general motions of the atmosphere it is quite common to consider the viscosity of the air as a resisting force, but the above figures show that it exerts an exceedingly feeble resistance as compared with the obstacles encountered on the earth's surface and the inertia of the rising and falling masses of warm and cold air. The coefficient of friction usually deduced from the observations of the winds results essentially not from viscosity, but from the resistances of all kinds to which the motion of the atmosphere is subjected. The greater part of these resistances consists essentially in a dissipation of the energy of the moving masses by their division into smaller masses which penetrate the quiet air in all

directions. The loss of energy due to this process, if it must be called friction, should perhaps be called convective friction, or, more properly, convective loss of energy.

Gravity.—The weight of the atmosphere depends primarily upon the action of gravity, which gives a downward pressure to every particle. Owing to the elastic compressibility of the air, this downward pressure is converted at once into an elastic pressure in all directions. The force of gravity varies with the latitude and the altitude, and in any exact work its variations must be taken into account. Its value is well represented by the formula due to Helmholtz, $g=980.6 (1-0.0026 \cos 2L) \times (1-f/h)$, where L represents the latitude of the station and h the altitude. The coefficient f is small and has a different value according as the station is raised above the earth's surface by a continent, as, for instance, on a mountain top, or by the ocean, as on a ship sailing over the sea, or in the free air, as in a balloon. Its different values are sufficiently well known for meteorological uses, and are utilized most discreetly in the elaborate discussion of the hypsometric formula published by Angot in 1899 in the memoirs of the Central Meteorological Bureau of France.

The temperature of the air, at the surfaces of both the earth and ocean and throughout the atmosphere, is the fundamental element of both climatology and dynamic meteorology. As far as it is known from direct observation, it is best exhibited by means of isotherms or lines of equal temperature drawn on charts of the globe. It can also be expressed analytically by harmonic spherical functions, as was first done by Schöch. The normal distribution of temperature for each month of the year over the whole globe has been given by Buchan in his charts of 1868 and of 1888, also by the U.S. Weather Bureau "Bulletin A" of 1893, and again by Buchan in his new edition of Bartholomew's *Physical Atlas*, London, 1899. The temperatures, as thus charted, first receive a slight correction, called a reduction to sea-level, in order to reduce them to a homogeneous system. The actual temperature near the ground at any altitude on a continent or island may be obtained from these charts by subtracting 0.5° C. for each 100 metres of elevation of the ground above sea-level, or 1° F. for 350 feet. This reduction, however, applies specifically to temperatures observed near the surface of the ground, and cannot be used with any confidence to determine the temperature of points in the free air at any distance above the land or ocean. On all such charts the reader will notice the high temperatures near the ground in the interior of each of the continents in the summer season and the low temperatures in the winter season. In February the average temperatures in the northern hemisphere are not lowest near the North Pole, but in the interiors of Siberia and North America; in the southern hemisphere they are at the same time highest in Australia, and Africa, and South America. In August the average temperatures are unexpectedly high in the interior of Asia and North America, but low in Australia and Africa. The vertical distribution in the free air must also be studied in detail, in order to understand both the general circulation and the special systems that characterize the earth's atmosphere. Many observations on mountains and by aeronauts in balloons were made during the 19th century in order to ascertain the facts with regard to the decrease of temperature as we ascend in the atmosphere, but it is now recognized that both these classes of observations were largely affected by local influences due to the presence of the ground and the balloon. Later efforts have been directed to the elimination of these disturbing elements, and the determination of the temperature of the free

*Distribu-
tion of
tempera-
ture.*

air by means of delicate thermographs carried up to great heights by small free "sounding balloons," and to lesser heights by means of kites. Many international balloon ascents have been made since 1890, and a large amount of information has been secured. Reports upon these results have been published by Dr H. Hergesell for Europe in general, and by L. Teisserenc de Bort relative to that done at his private observatory for dynamic meteorology at Trappes, near Paris. Valuable work has also been done with kites, both at Trappes and by Mr A. Lawrence Rotch at his private meteorological observatory on Blue Hill, near Boston; but the principal work with kites has been that accomplished in 1898 at the seventeen kite stations of the U.S. Weather Bureau. The first results of all this latter work are published in a memoir, "Bulletin F," by Dr H. C. Frankenfield, of which a summary is given in the *U.S. Monthly Weather Review* for September 1899. Some of the more general results are given in the following table:—

Stations.	Altitude. Feet.	Temperature.	
		Gradient.	Reduction.
		Fahr.	Fahr.
		°	°
Washington	210	-3.00	-15.2
Cairo	315	-4.30	-25.6
Cincinnati	940	-5.15	-27.5
Fort Smith	527	?	?
Knoxville	990	-5.00	-21.5
Memphis	319	-3.50	-17.3
Springfield	684	-3.85	-17.7
Cleveland	705	-4.10	-18.8
Duluth	1197	-4.30	-17.6
Lansing	869	-3.85	-17.0
Sault Ste Marie	722	-3.45	-15.7
Dodge	2473	-4.10	-11.6
Dubuque	894	-3.30	-14.5
North Platte	2811	-5.40	-13.3
Omaha	1241	-3.20	-12.9
Pierre	1595	-3.90	-14.4
Topeka	972	-3.83	-16.5

In this table the second column gives the altitude of the ground at the reel on which the kite wire was wound. The third column shows the average gradient in degrees Fahrenheit per 1000 feet above the reel at the respective stations, up to a uniform surface 5280 feet above sea-level. The fourth column shows the total reduction to be applied to the temperature at the reel in order to obtain the temperature at the one-mile level above sea. These gradients and reductions are based upon observations made only during the six warm months from May to October 1898. At the observatory of Trappes free balloons and kites were used during eighteen months, in 1898 and 1899, with sufficient frequency to give us some knowledge of the monthly gradients of temperature in a vertical direction and a fair average for a whole year. The following results are taken from the *U.S. Monthly Weather Review*, September 1899:—

Decrease of Temperature in Free Air.

Altitude above ground.	Annual.	May-Oct.	Nov.-Apr.
Kil.	Cent.	Cent.	Cent.
10	-60.1	-63.7	-56.5
9	-51.4	-54.5	-48.3
8	-44.7	-47.2	-42.2
7	-37.7	-39.5	-35.8
6	-30.2	-31.1	-29.2
5	-24.2	-25.3	-23.2
4	-18.3	-19.9	-16.7
3	-13.2	-15.3	-11.0
2	- 8.6	-10.3	- 6.8
1	- 4.0	- 5.7	- 2.3
0	0.0	0.0	0.0

It is evident that the annual average vertical gradient of temperature is between 4° and 6° C. per thousand metres of ascent in the free air. In the summer months—May–October—the gradient up to 6000 kilometres agrees closely with the value 5° per thousand metres, which has come into extensive use since the year 1890 on the recommendation and authority of Hann. The winter gradients are apparently less than those for summer, possibly owing to the influence of the condensation into cloud and rain during the winter season in France; the same value may not result from the kite work in the United States, where the clouds and precipitation of winter do not so greatly exceed those of summer. The work at Trappes is therefore not necessarily representative of the general average of the northern hemisphere, but belongs to a region in which during the summer time, at great heights, the air is cooler than in the winter time, since during the latter season there is an extensive flow of warm air from the ocean over the cold air from the land. The isotherms at 5000 and 10,000 metres altitude over all Europe, on three special days when many ascensions were made, are published by Hergesell in the *Met. Zeit.* for January 1900, and show unexpectedly great diversities at those altitudes.

The distribution of aqueous vapour is best shown by lines of equal dew-point or vapour tension, though for some purposes lines of equal relative humidity are convenient. The dew-point lines are not usually shown on charts, partly because the lines of vapour pressure are approximately parallel to the lines of mean temperature of the air, and partly because the observations are of very unequal accuracy in different portions of the globe. In general we may consider any isotherm as agreeing with the dew-point line for dew-points a few degrees lower than the temperature of the air. The distribution of moisture is quite irregular both in a horizontal and in a vertical direction. On charts of the world we may draw lines based on actual observations to represent equal degrees of relative humidity, or equal dew-points and vapour pressures; but as regards the distribution of moisture in a vertical direction we are, in the absence of specific observations, generally forced to assume that the vapour pressure at any altitude h follows the average law first deduced from a limited number of observations by Hann, and expressed by the logarithmic equation, $\log. e = \log. e_0 - h/6517$, which is quite analogous to the elementary hypsometric formula, $\log. p = \log. p_0 - h/18400$. Therefore, in general, the ratio between the pressure of the vapour and the pressure of the atmosphere at any altitude is represented by the approximate formula, $\log. e/p = \log. e_0/p_0 - h/10091$. Of course these relations can only represent average or normal conditions, which may be departed from very widely at any moment. They have, however, been found to agree remarkably with all observations which have as yet been published. The average results are given in the following table, which is abbreviated from one published by Hann, but with the addition of the work done by the U.S. Weather Bureau, as reduced by Dr Frankenfield in 1899.

It is therefore evident that the formula first published by Hann in 1874 as the result of observations on fifteen balloon ascents and six mountains, by means of which the last line in the table was computed, is abundantly confirmed by the Weather Bureau work in the United States with kites and balloons. The distribution of vapour it indicates is wholly different from that assumed by Dalton and the physicists who followed him. It is not the law of diffusion, but it agrees so closely with actual observations up to altitudes of five miles that we may safely assert that the vapour constituent

Distribution of aqueous vapour.

of the atmosphere is not distributed according to the law of gaseous diffusion, but, like temperature and the ratio between oxygen and nitrogen, is controlled by other laws prescribed by the winds and currents, namely—convection.

Diminution of the Relative Vapor Pressure with Altitude.

Authority.	1500 feet.	2000 feet.	3000 feet.	4000 feet.	5000 feet.	6000 feet.	7000 feet.	8000 feet.	No. Obs.

Hann. Computed by Hann.	0.85	0.81	0.72	0.65	0.58	0.52	0.47	0.42	—

Note.—The vapour pressure at any altitude is supposed to be expressed as a fraction of that observed at the ground. When the altitudes are given in feet Hann's formula becomes $\log e/e_0 = -h/29539$.

The total amount of vapour in the atmosphere is between one-fourth and one-fifth of the amount required by Dalton's hypothesis, as is illustrated by the following table taken from an article by the writer in the Smithsonian Report for 1888, page 410:—

Total Vapour in a Vertical Column.

Altitude. Feet.	Relative Tension = e/e_0 .	Actual Weight Gr. per Cubic Foot.				Total Vapour in the Columns expressed as Inches of Rain.			
		80° F.	70° F.	60° F.	50° F.	80° F.	70° F.	60° F.	50° F.
0	1.000	10.95	7.99	5.76	4.09	0.0	0.0	0.0	0.0

18,000	0.144	1.58	1.15	0.83	0.59	2.5	1.8	1.3	0.9
24,000	0.075	0.82	0.62	0.43	0.31	2.7	2.0	1.4	1.0
30,000	0.040	0.43	0.32	0.23	0.16	2.8	2.1	1.5	1.1

We see that a heavy rainfall may result from the precipitation of only a small percentage of the water contained in the fresh supplies of air brought by the wind, and that consequently, if all moisture were abstracted from the atmosphere throughout the equatorial regions, it could only affect the barometer by 2.8/13.6 inches, or about two-tenths of an inch, while at the polar regions the diminution would be much less than one-tenth. Evidently, therefore, it is idle to argue that the fall of pressure in an extensive storm is to be considered as the simple result of the condensation of the vapour into rain.

The horizontal distribution of barometric pressure over the earth's surface is shown by the isobars, or lines of equal pressure; it can also be expressed by a system of complex spherical harmonics. As the indications of the mercurial barometer must vary with the variation of gravity, whereas those of the aneroid barometer do not, it has been agreed by the International Meteorological Conventions that for scientific purposes all atmospheric pressures, when expressed in barometric inches, must be reduced to one standard value of gravity, namely, its force at sea-level and at 45° of latitude. In this locality its value is such as to give an acceleration of 980.8 centimetres, or 32.2 English feet, per second. The effect of the variation of gravity with latitude is therefore to make the mercurial barometer read too high, between 45° and the equator; and too low, between 45° and the pole. The correction to be applied to any mercurial barometric reading at or near sea-level, in order to get the

Barometric pressure.

atmospheric pressure in standard units, should be given on the edge of a meteorological chart, unless the isobars shown thereon already contain this correction. On such charts it will be perceived that the barometric pressure at sea-level is by no means uniform over the earth's surface, and daily weather charts show very great fluctuations in this respect, the lowest pressures being storm centres and the highest ones areas of clear cold weather. But even the normal average charts show high pressures over the continents in the winter and low pressures over the oceans, these conditions being reversed in the summer time. Schouff (*Pogg. Ann.*, 1832) first demonstrated that the average pressure in the neighbourhood of the equator is slightly less than under either tropic, and that there is a still more remarkable diminution of pressure from either tropic towards its pole. The exact statement of these variations of pressure with latitude was subsequently worked out very precisely by Ferrel, and forms the basis of his explanation of the general circulation of the earth's atmosphere and its influence on the barometer. The series of monthly charts for the whole globe, compiled by Buchan and published by the Royal Society of Edinburgh in 1868, as well as Buchan's later and more perfect charts in the meteorology of the *Challenger* Expedition, Edinburgh, 1889, first revealed clearly the fact that the distinct areas of high and low pressure which are located over the continents and the oceans vary during the year in a fairly regular manner, so that the pressure is higher over the continents in the winter season and lower in the summer season, the amount of the change depending principally upon the size of the continent. A part of this annual variation in pressure is undoubtedly introduced by the methods of reduction to sea-level; indeed, if the data of the lower stations are reduced up to the level of 10,000 or 15,000 feet, we sometimes find the barometric conditions quite reversed. These annual changes are intimately connected as cause and effect with the annual changes of temperature, moisture, and wind, but it is quite erroneous to imagine that the observed pressures control the winds; there is a reaction going on between the wind and the barometric pressure, and the resistance of the earth's surface is such that the true relation between these factors is a complex but fundamental problem of theoretical meteorology.

The vertical distribution of pressure as deduced from observation shows a rate of diminution with increasing altitude very closely but not entirely accordant with the laws of static equilibrium, as first elaborated by Laplace in his hypsometric formula. The departures from the law of static equilibrium are sufficient to show that, if our atmosphere is really in a state of equilibrium, it must be a matter of dynamics and not of statics. The relation of the density of the air to the altitude and temperature, and the total pressure of the superincumbent atmosphere, are shown in the accompanying diagram (Fig. 1), which is taken from a paper by the late Joseph Cottier, published in the *U.S. Monthly Weather Review* for July 1897. The diminution of pressure with altitude, as shown in this diagram for average conditions, but not for the temporary conditions that continually occur, follows a logarithmic law, and can undoubtedly be extended upwards for the normal atmosphere to a height of 20 or 30 miles, but not much farther, owing to our uncertainty as to the actual temperature and pressure in the upper portions of the atmosphere. This diagram is based upon the assumption that the atmosphere is in a state of convective equilibrium; the ascending and descending masses expand and cool as they ascend, or contract and warm up as they descend, nearly but not quite in accordance with the adiabatic law of the change of temperature in pure gases. The limiting height of the atmosphere must be at some known elevation

above 20 or 30 miles, where the temperature would become absolute zero, according to the adopted law of diminution. But the uncertainty of the various hypotheses as to the physical properties of the upper atmosphere forbids us to entertain any positive ideas on this subject at the present time. If we define the outer limit as that point at which the diffusion of gases inwards just balances the diffusion outwards, then this limit must be determined not by the hypsometric formula, but by the properties of gases at low temperatures and pressures under conditions as yet uninvestigated by physicists.

It is evident that the clouds are formed from clear transparent air by the condensation of the invisible moisture therein into numerous minute globules of water or crystals of ice and snow. Notwithstanding their transparency, these individual globules and crystals, when collected in large masses, disperse the solar rays by reflexion to such an extent that direct light from the sun is unable to penetrate them, and partial darkness results. In a general survey of the atmosphere the geographical distribution of the amount of cloudy sky is important. When the solar heat falls upon the surface of the cloud it is so absorbed and reflected that, on the one hand, scarcely any penetrates to the ground beneath, while on the other hand the upper surface of the cloud becomes unduly heated. Even if this upper surface is completely evaporated, it may continually be renewed from below, and, moreover, the evaporated moisture mixing with the air renders it very much lighter specifically than it would otherwise be. Hence the upper surface of the cloud replaces the surface of the ground and of

Fig. 1.

the ocean; the air in contact with it acquires a higher temperature and greater buoyancy, while the ground and air beneath it remain colder than they would be in sunshine. The average annual cloudiness over the globe is therefore intimately related to the density and circulation of the atmosphere; it was first charted in general terms by L. Teisserenc de Bort of Paris about 1886. The manifold modifications of the clouds impress one with the conviction that, when properly understood and interpreted, they will reveal to us the most important features of the processes going on in the atmosphere. If the farmer and sailor can correctly judge

of the weather several hours in advance by a casual glance at the clouds, what may not the professional meteorologist hope to do by a more careful study? Acting on this idea, the author in 1868 asked from all of his correspondent observers full details as to the quantity, kind, and direction of motion of each layer of clouds; these were telegraphed daily for publication in the bulletin of the Cincinnati Observatory, and for use in the weather predictions made at that time. Since January 1872 similar data have been regularly telegraphed for the use of the U.S. Weather Bureau in preparing forecasts, although the special cloud maps that are compiled have not been published, owing to the expense. These data were also published in full in the *Bulletin of the International Simultaneous Meteorological Observations* for the whole northern hemisphere during the years 1875-84. The writer's work on the U.S. Eclipse Expedition to the West Coast of Africa in 1889-90 was wholly devoted to the determination of the height and motions of the clouds by the use of a special form of the marine nephoscope, whose use can easily be understood from an examination of Figs. 2, 3, and 4. It consists simply of a framework and mirror fitting upon the standard compass of the navigator, and removable at a moment's notice if necessary. The use of this instrument is to be strongly recommended, as it gives the navigator a means of determining exactly the bearing of a storm centre at sea by studying the lower clouds better than he can possibly do by the observations of the winds alone. The importance of cloud study has been especially emphasized by the International Meteorological Committee, which arranged for a complete year of systematic cloud-work by national weather bureaus and individual observatories throughout the world from May 1896 to June 1897. In this connexion Mr H. C. Clayton of Blue Hill Observatory has published a very comprehensive report on cloud forms. The complete report by Professor F. H. Bigelow on the work done by the U.S. Weather Bureau forms a part of the annual report for 1899, and constitutes a remarkable addition to our knowledge of the subject. Some preliminary account of this work was published in the *American Journal of Science* for December 1899.

In order to obtain the greatest benefit from the study of the clouds, we must understand the laws and processes involved in their formation; but as these constitute a study in mechanics and physics of great complexity, the results already obtained will be stated in a subsequent section of this article as a part of theoretical physical meteorology. Meanwhile the following brief remarks relative to the kinds of clouds will serve as an introduction to the subject. The name *stratus* implies a horizontal sheet of cloud having no special structure, except that it is a thin layer. It was first applied by Howard specifically to the thin layers that form within a short distance of the earth's surface in quiet places on a still evening, preliminary to the general formation of low fog at night; therefore it is sometimes called high or lifted fog. It is also applicable to thicker layers that form at considerable heights above the ground, and by cutting off radiation effectually prevent the formation of fog at the earth's surface. Again, the term is applied to layers of haze that may form even at the highest altitude. Near the observer's zenith such a layer usually appears as haze, but when seen in the distant horizon it appears as a horizontal layer of stratus. Finally the term is applied in various combinations to indicate, for instance, that the main cloud has a broad thin base, like a stratus, attached to its lower part or broad horizontal sheets overflowing at the top.

The presence of a stratus cloud indicates that there is no rapid or great vertical motion going on, such as would throw a thin layer of stratus into great rolls or heaps. *Cumulus* may be described as the direct result of rapidly ascending currents that have been started either by the buoyancy of the warm air at the surface of the earth or at the surface of a stratus cloud. But it is also formed by the direct action of moist winds, which, blowing against mountains or other obstacles, are forced to rise rapidly. In either case the ascending air must expand as it comes under the low pressure of greater altitudes, and as it does work in expanding, it must cool by an amount that is determined by the laws of thermodynamics. This cooling is distinctly not due to any great extent to mixture with cold air, the radiation of heat, or the so-called cold of altitude, but, as Espy first maintained in 1826, is a simple thermodynamic operation, by which heat is converted into work, or work that is done makes a draft upon the available heat that is contained in the air. At a certain point of its ascent the air thus cools sufficiently to form haze and cloud. Espy showed that the latent heat evolved in the formation of the cloud may become again apparent if the cloudy air is forced to descend, so that, except for a small loss by radiation, the air will return to the same temperature as that with which it started. If, however, rain or snow should fall from the clouds leaving the evolved latent heat behind, then when the cloudy air returns to the ground it is drier and warmer than in its initial condition, and thus gives rise to the hot waves known as chinooks and foehns; or if the process goes on over a large area of the earth, it causes regions of drought and even deserts. *Alto-cumulus* is a comparatively thin layer of clouds of the cumulus type, occurring in cases where the ascending currents are not strong enough, or do not continue long enough, to stimulate the formation of very high or thick cumuli. Sometimes these clouds represent the upper portions of a series of waves in the atmosphere. At other times they are formed between two layers of air, of which the upper one has a different velocity and direction of motion from the lower one; consequently, at the boundary surface a series of rolls or horizontal cylindrical vortices are produced, and the cloudiness is due partly to mixture and partly to the expansion of the air in the rising portion of the clouds. Systems of alto-cumulus rolls sometimes extend for several hundred miles in all directions, or in a straight line for a hundred miles to leeward of a mountain top. *Cirro-cumulus* is much smaller than the alto-cumulus, of a more delicate texture, purer white, and almost invariably arranged in rank and file or other very regular patterns. It is formed, like the alto-cumulus, in the mixing regions between two layers of air moving in different directions, but its typical peculiarities apparently arise from the fact that it is formed at such high altitudes and low temperatures that it can only consist of the finest crystals of ice and snow. It is so thin or contains so little water that it scarcely ever presents a dark side having an appreciable contrast to the bright side; in other words, the sunlight seems to illuminate it through and through. *Cirrus* clouds appear both singly and in large groups—generally of a pure white—sometimes in belts or bands, which converge by perspective in opposite points of the horizon, and whose actual length is therefore to be measured by several hundred miles. They are the highest and whitest of all the clouds; they may be formed by mixture, or even sometimes by mere contact and the conduction of their own heat to neighbouring cold air. More frequently they must be due to cooling of moist streaks in the upper atmosphere by expansion and radiation. As soon as these clouds are formed in daylight, the heat of the sunshine begins to dissipate them, and they

soon disappear if they are surrounded by very dry air; but, if the air be moist, the same process that formed the first cirrus will continue until the whole layer of air becomes filled with a thick haze which indicates the presence of conditions favourable to a storm.

II. APPARATUS AND METHODS.

The observational basis of meteorology is the frequent, and, if possible, continuous record of the temperature, moisture, and barometric pressure in the free atmosphere, the direction and velocity of the wind, the rain and snow fall, and the kind, amount, and motion of the clouds. For Europe these data have been furnished with more or less accuracy and continuity by thousands of observers ever since 1553, when Ferdinand II., grand duke of Tuscany, organized a system of daily observations in Italy under the general supervision of Luigi Antinori. During the 19th century great efforts were made to obtain equally full records from all parts of the land and ocean, and thousands of navigators were added to the great corps of observers. Other matters have also been investigated, the most important being the intensity of radiation from the earth at night-time and from the sun by day-time, the optical phenomena of the sky, the amount of dust in the air, the electrical condition and the chemical constitution of the atmosphere. Although all the instruments used belong to the category of physical apparatus, yet certain points must be considered as peculiar to their use in connexion with meteorology.

In using the thermometer to determine the temperature of the free air it is necessary to consider not merely its intrinsic accuracy as compared with the standard gas thermometer of the International Bureau of Weights and Measures at Paris, but especially its sluggishness, the influence of noxious radiations, the gradual change of its zero point with time, and the influence of atmospheric pressure.

Sensitiveness.—The thermometer indicates the temperature of the outside surface of its own bulb only when the whole mass of the instrument has a uniform temperature. Assuming that by appropriate convection we can keep the surface of the thermometer at the temperature of the air, we have still to remember that ordinarily this itself is perpetually changing both in rapid oscillations of several degrees and in diurnal periods of many degrees, while the thermometer, on account of its own mass or thermal inertia, always lags behind the changes in the temperature of its own surface. On the other hand, radiant heat passes easily through the air, strikes the thermometer, and raises its temperature quite independently of the influence of the air whose temperature we wish to measure. The internal sluggishness or the sensitiveness of the thermometer is usually different for rising and for falling temperature, and is measured by a coefficient which must be determined experimentally for each instrument by observing the rate at which its indications change when it is plunged into a well-stirred bath of water whose temperature is either higher or lower than its own. This coefficient indicates the rate per minute at which the readings change when the temperature of the surface of the bulb is one degree warmer or colder than the temperature of the bath. Such coefficients usually vary between $\frac{1}{10}$ th of a degree centigrade for sluggish thermometers, and one or two degrees for very sensitive thermometers. Suppose, for instance, that the coefficient is one-half degree, then when the rate of change in the temperature of the air is one degree per minute it is exactly the same as that which the thermometer itself undergoes when its own temperature is two degrees different from that of the air; consequently, the thermometer will lag behind the air temperature to that extent and by that amount of time, assuming that the air itself flows fast enough to keep the surface of the bulb at the air temperature. When the air temperature ceases to rise or fall, and begins to change at the same rate in the opposite direction, the thermometer will fail to record the true maximum or minimum temperature by an appreciable error depending upon the rapidity of the change, and will follow the new temperature changes with the same lag. For example, in the case just quoted, if a rising temperature suddenly changes to a falling temperature, the error of the thermometer at the maximum temperature will be two degrees, and yet the ther-

mometer may be absolutely correct as compared with the standard when it is allowed five or ten minutes' time to overcome the sluggishness. It is very difficult to obtain the temperature of the free air at any moment within $\frac{1}{10}$ of a degree centigrade, owing to the sluggishness of all ordinary thermometers and the perpetual variations in the temperatures of the atmospheric currents.

Radiation.—When a thermometer bulb is immersed in a bath of liquid all radiant heat is cut off, but when hung in the open air it is subject to a perpetual interchange of radiations between itself and all its surroundings; consequently its own temperature has only an indirect connexion with that of the air adjacent to it. One of the most difficult problems of meteorology is so to expose a thermometer as to cut off noxious radiations and get the true temperature of the atmosphere at that spot. The following are a few of the many methods that have been adopted to secure this end:—Melloni put the naked glass bulbs within open sheltering caps of perforated silver paper. Flaugergues used a protection consisting of a simple vertical cylinder of two sheets of silver paper enclosing a thin layer of non-conducting substance, like cotton or wool. The influence of radiation upon a thermometer depends upon the radiating and absorbing powers of its own surface; a roughened surface of lamp-black radiates and absorbs perfectly; one of chalk powder does nearly as well; glass much more but imperfectly; while a polished silver surface reflects with ease, but radiates and absorbs with the greatest difficulty. Fourier proposed to use two thermometers side by side, one of plain glass and the other of blackened glass; the difference of these would indicate the effect of radiation at any moment; but instead of plain glass he should have used polished silver. His method was quite independently devised and used by the writer in 1865 and 1866 at Pulkowa, where the thermometers were placed within a very light shelter of oiled paper. In order to use this method successfully, both the black and the silvered thermometers should be whirled side by side inside the thermometer shelters (see *Bulletin of the Philosophical Society of Washington* for 1883). Various forms of open lattice work and louver screens have been devised and used by Glaisher, Kupffer, Stevenson, Stowe, Dove, Renou, Joseph Henry, and others, in all of which the wind is supposed to blow freely through the screens, while the latter cut off the greater part of the direct sunshine and other obnoxious radiations by day, and also prevent obnoxious radiation from the thermometer to the sky by night. The Italian physicist Belli first proposed a special artificial ventilation drawing the fresh air from the outside and making it flow rapidly over the thermometer. Even before his day de Saussure, Espy, Arago, and Bravais whirled the thermometer rapidly either by a small whirling machine, or by attaching it to a string and swivel and whirling it like a sling. When this whirling is done in a shady place excellent results are obtained. Renou and Craig placed the thermometer in a thin metallic enclosure or shelter, and whirled the latter. Wild established the thermometer in a fixed louver shelter, but by means of a ventilating apparatus drew currents of fresh air from below into the shelter, where they circulated rapidly and passed out. In Germany, since 1885, Dr Assmann has developed the apparatus known as the ventilated psychrometer, in which the dry-bulb thermometer is placed within a double shelter of thin metallic tubing, and the air is drawn in rapidly by means of a small ventilating fan. In the observations made by the writer on the cruise of the *Pensacola* to the west coast of Africa, the dry- and wet-bulb thermometers were enclosed within bamboo tubes and rapidly whirled. The inside of the wet-bulb tube was kept wet, so that its surface being cooled by evaporation could not radiate injuriously to the thermometer. In the system of exposure adopted by the U.S. Weather Bureau the dry and wet bulbs are whirled by a special apparatus fixed within the louvered shelter, which is about $3\frac{1}{2}$ feet cube, and is placed far enough above the ground or building to ensure free exposure to the wind. In using the whirling and ventilating methods it is customary to take a reading after whirling one minute, and a second reading at the end of the second minute, and so on until no appreciable changes are shown in the thermometer. Of course in perfectly calm weather these methods can only give the temperature of the air for the exact locality of the thermometer. On the other hand, when a strong wind is blowing the indicated temperature is an average that represents the long narrow stream of air that has blown past the thermometer during the few minutes that are necessary in order that the bulb may obtain approximately the temperature of the air.

Change of Zero.—All thermometers having glass bulbs, especially those of cylindrical shape, are sensitive to changes of atmospheric pressure. The freezing-point, determined under a barometric pressure of 30 inches, or at sea-level, stands higher on the glass tube than if it had been determined under a lower pressure on a mountain top. Therefore delicate thermometers, when transported to great heights, or even during the very low pressure of a storm centre, read too low and need correction. The zero-point also changes with time and with the method of treatment that the bulb has received, owing to the slow adjustment of the molecules

of the glass bulb to the state of stable equilibrium. Their relations among themselves are disturbed whenever the bulb is freshly heated. At this time the freezing-point is depressed to an amount nearly proportional to the heating. The normal method of treatment consists in first determining the boiling-point of the thermometer, and, after a few minutes, the freezing-point. If this method is uniformly followed the two fiducial points will stay in permanent relation to each other. A thermometer that has been used for many years by a faithful meteorological observer has almost inevitably been going through a steady series of changes; in the course of ten years its freezing-point may have risen by 2° or 3° F., and, moreover, it changes by fully a tenth of a degree between summer and winter. The only way completely to eliminate this source of error from meteorological work is to discard the mercurial thermometer altogether; but, instead of adopting that course, the use is generally recommended of thermometers whose bulbs are made of a special glass, upon which heating and cooling have comparatively very little influence. Any argument as to secular changes in the temperature of the atmosphere is likely to be greatly weakened by the unknown influence of this source of error, as well as by changes in the methods of exposure and in the hours of observation.

The barometer indicates the elastic pressure prevailing in gas or liquid at the surface of the mercury in the open tube or cistern, provided that the fluid at that point is in a state of quiet relative to the mercury. Any motion of the air will have an influence upon the reading quite independently of the prevailing elastic pressure. The pressure within a mass of gas at any point is the summation of the effects due to the motions of the myriad molecules of the gas at that point; it is the kinetic energy of the molecules striking against each other and the sides of the enclosure, which in this case is the surface of the mercury in the cistern of the instrument. If the barometer moves with respect to the general mass of the gas there is a change in the pressure on the mercurial surface, although there may be none in the general mass of the free gas, and a barometer giving correctly the pressure of the air at rest within a room will give a different indication if the instrument or the air is set in rapid motion so that the air strikes violently against it. If the barometer moves with the air it will indicate the elastic pressure within the air. When the wind blows against an obstacle the air pressure is increased slightly on the windward side and diminished on the leeward side. It is thus obvious that in determining the pressure within the free atmosphere the exposure of the barometer must be carefully considered. The other sources of error that give rise to discrepancies in meteorological work relate to the temperature of the instrument, the sluggishness of the movement of the mercury, and the secular changes in the correction for capillarity, due principally to the changes in the condition of the surfaces of the glass and the mercury, especially those that are exposed to the open air. The international comparisons of barometers show that discrepancies exist between the best normals or standards, and that ordinary barometers must always be compared with such standards at the temperatures and pressures for which they are to be used. The influence of a gale of wind is to raise the elastic pressure within a room whose window faces to the windward, but to lower the pressure if the window faces to the leeward. The influence of the draught up chimney, produced by the wind blowing over its summit, is to lower the pressure within the room. The maximum effect of the wind in raising the pressure is given by the formula, $P - P_0 = 0.0000383 \times V^2$, where the pressure is given in inches and the velocity in miles per hour. This amounts to about one-tenth of an inch in a 50-mile wind, and to nearly four-tenths in a 100-mile wind. The diminution by a leeward window or a draught up chimney is usually less than this amount. This alteration in pressure, due to the local effect of wind, does not belong to the free atmosphere but to the method of exposure of the barometer, and can be eliminated only by

Barometer.

methods first described by the author in 1882: it is a very different matter from the general diminution of pressure in the atmosphere produced by the movement of the wind over a rotating earth and by the centrifugal force within a vortex. The latter is an atmospheric phenomenon independent of instruments and locality in hurricanes and tornadoes which may amount to several inches of the mercurial column. It is, however, quite common to find in the continuous records of pressure during a hurricane evidence of the fact that the low pressure due to the hurricane and the special diminution due to the exposure of the barometer are combined together, so that when the calm centre of a hurricane passes over a station the pressure temporarily rises by the amount due to the sudden stoppage of the local exposure effect.

The wind is measured either by means of its pressure against any obstacle or by revolving apparatus that gives some idea of the velocity of its movement. The pressure is supposed to interest the engineer and navigator, but the velocity is the fundamental meteorological datum; in fact, the pressure varies so much with the nature of the obstacle and method of exposure, and the density of the air, that it has no real importance in the study of the movements of the atmosphere. Pressure anemometers date from the pendulous tablet devised by Sir Christopher Wren about 1667, and such pressure plates continue to be used in an improved form by Russian observers. Normal pressure plates are used at a few English and Continental stations. The windmill anemometers devised by Schober and Woltmann were modified by Combes and Casella so as to make an exceedingly delicate instrument for laboratory use; another modification by Richard is extensively used by French observers. In the early part of the 19th century Edgeworth devised and Robinson perfected a windmill system in which hemispherical cups revolved around a vertical axis, and these have come into general use in both Europe and America. Many studies have been made of the exact ratio between the velocity of the wind and the rotations of the Robinson anemometer. The factor 3 is usually adopted and incorporated into the mechanism of the apparatus, but in ordinary circumstances this factor is entirely too large, and the recorded velocities are therefore too large. The whirling cups do not revolve with any simple relation to the velocity of the wind, even when this is perfectly steady. The relation varies with the dimensions of the cups and arms and the speed of the wind, but especially with the steadiness or gustiness of the wind. The exact ratio must always be determined experimentally for each specific type of instrument; in most instruments in actual use the factor for steady wind varies between 2.4 and 2.6. When the wind is gusty the inertia of the moving parts of the instrument necessitates an appreciable correction; thus, when the gust is at its height the revolving parts receive an impetus that lasts after the gust has gone down, so that the actual velocity of the cups is too high. For this reason, also, comparisons and studies of anemometers made in the irregular natural winds of a free air are unsatisfactory. For the average winds at Washington, D.C., and on Mount Washington, N.H., and the standard instruments used in the U.S. Weather Bureau service, Professor C. F. Marvin, however, deduced the following table for reduction from recorded to true velocity. This table involves the moment of inertia of the revolving parts of the instrument and the gustiness of the winds at Washington, and will therefore of course not apply strictly to other types of instruments or winds, for which special studies must be made.

Marvin's Table for the Reduction to True Velocities of the Data given by Robinson's Anemometer.

Indicated Velocity. Miles.	True Velocity.									
	0	1	2	3	4	5	6	7	8	9
0	5.1	6.0	6.9	7.8	8.7
10	9.6	10.4	11.3	12.1	12.9	13.8	14.6	15.4	16.2	17.0
20	17.8	18.6	19.4	20.2	21.0	21.8	22.6	23.4	24.2	24.9
30	25.7	26.5	27.5	28.0	28.8	29.6	30.3	31.1	31.8	32.6
40	33.3	34.1	34.8	35.6	36.3	37.1	37.8	38.5	39.3	40.0
50	40.8	41.5	42.2	43.0	43.7	44.4	45.1	45.9	46.6	47.3
60	48.0	48.7	49.4	50.2	50.9	51.6	52.3	53.0	53.8	54.5
70	55.2	55.9	56.6	57.3	58.0	58.7	59.4	60.1	60.8	61.5

90	69.2

About 1842 a committee of the American Academy of Arts and Sciences experimentally determined, for a large variety of chimney caps, or cowls, or hoods, the amount of suction that produces the draught up a chimney, and shortly afterwards a similar committee made a similar investigation at Philadelphia (see *Proc. Amer. Acad.* vol. i. p. 307, and *Journal of Franklin Institute*, vol. iv. p. 101). These investigations showed that the open end of the chimney, acting as an obstacle in the wind, is covered by a layer of air moving more rapidly than the free air at a little distance, and that therefore between this layer and the aperture of the chimney there is a space within which barometric pressure is less than in the neighbouring free air. The draught up the chimney is due to the pressure of the air at the lower end or fireplace pushing up the flue into this region of low pressure, quite as much as to the buoyancy of the heated air within the flue. From such experiments as these there has been developed the vertical suction-tube anemometer, as devised by Fletcher in 1867 and re-invented by Hagemann in 1876, and introduced into England by Dines. Two vertical tubes whose apertures are respectively directed to the windward and the leeward, and within which are two independent barometers, give the means of determining the barometric pressure plus the wind pressure and minus the wind pressure respectively, so that both the velocity of the wind and the true barometric pressure can be determined. If instead of a simple opening at the top of the tube we place there horizontally the contracted Venturi's tube, we obtain a maximum wind effect, which gives an accurate measure of the wind velocity, and is the form recommended by Bourdon as an improvement on that of Arson. In all anemometers of this class the inertia of the moving parts is reduced to a minimum, and the measurement of rapid changes in velocity and of the maximum intensity of gusts becomes feasible. On the other hand, these researches have shown how to expose a barometer so that it shall be free from the dynamic or wind effect even in a gale. It has only to be placed within a room or box that is connected with the free air by a tube that ends in a pair of parallel plane plates. When the wind blows past the end of this tube it flows between these plates in steady linear motion, and can produce no disturbance of pressure at the mouth of the tube if the plates are at a suitable distance apart. This condition of stable flow, as contrasted with permanent flow, was first defined by Sir William Thomson (Lord Kelvin) (see *Phil. Mag.*, September 1887). Such a pair of small circular plates can easily be applied to a tube screwed into the air-hole at the back of any aneroid barometer, and thus render it independent of the influence of the wind.

As to the exposure of the anemometer, no uniform rules have as yet been adopted. Since the wind is subject to exceedingly great disturbances by the obstacles near the ground, an observer who estimates the force of the wind

by noticing all that goes on over a large region, or about him, has some advantage over an instrument that can only record the wind prevailing at one spot. The practice of the U.S. Weather Bureau has been to insist upon the perfectly free exposure of the anemometer as high as can possibly be attained above buildings, trees, and hills; but of course, in such cases, the instruments give records for an elevated point, and not for the ground. They are therefore not precisely appropriate for use in hygienic and agricultural studies, but they yield the records needed for general dynamic meteorology and proper for comparison with the isobars and the movements of the clouds shown on the daily weather map.

Moisture floats in the atmosphere either as invisible vapour or as visible haze, mist, and cloud. The presence of the latter generally assures us that the air is fully saturated. The total amount of both visible and invisible vapour contained in a unit volume of cloud or mist is directly determined by the Schwackhofer or Svenson hygrometer, or it may be ascertained by warming a definite portion of the air and fog and measuring the tension of the vapour by Edelmann's apparatus. Both these methods, however, are in practice open to many practical sources of error. If only invisible aqueous vapour is present we may determine its amount by several methods—(a) the chemical method, by absorbing and weighing it; (b) the dew-point method, by cooling the air down to the temperature where condensation begins; (c) Edelmann's method, by absorbing the moisture chemically and measuring the change in vapour tension; (d) by adding vapour until the air is saturated and measuring either the increased tension or the quantity of evaporation; (e) the psychrometric method, by determining the temperature of evaporation. The wet-bulb thermometer, which is the essential feature of the last method, was used by Baumé in 1758 and de Saussure in 1787, but merely as giving an index of the dryness of the air. The correct theory of its action has been elaborated by many investigators—Ivory, 1822; August, 1825; Apjohn, 1834; Belli, 1838; Regnault, 1845. From the last date until recent years no important progress was made in our knowledge of the subject, and it was supposed that the psychrometer was necessarily crude and unsatisfactory, but in its modern form it has become an instrument of much greater precision, probably quite as trustworthy as the dew-point apparatus or other method of determining atmospheric moisture. In order to attain this accuracy the two bulbs must be of the same size, style, and sensitiveness; the wet bulb must be covered with thin muslin saturated with pure water; both thermometers must be whirled or ventilated rapidly, but at the definite prearranged rate for which the tables of reduction have been computed; and, finally, both thermometers must be carefully sheltered against obnoxious radiations. In order to attain these conditions European observers tend to adopt Assmann's ventilated psychrometer, but American observers adopt Arago's whirled psychrometer, set up within an ordinary thermometer shelter. By either method an accuracy of one-tenth degree C. or two-tenths Fahrenheit should be attained. As a crude approximation, we may assume that the temperature of the dew-point is below the temperature of the wet bulb as far as that is below the dry bulb. A greater accuracy can be attained by the use of Ferrel's or Marvin's psychrometric tables. Glaisher deduced empirically from a large mass of observations certain factors for computing the dew-point, but these do not represent the accuracy that can be attained with the whirled psychrometer, nor are they thoroughly satisfactory when used with Regnault's tables and the stationary psychrometer. Especially should their use be discarded when the wet

bulb is greatly depressed below the dry bulb and the atmosphere correspondingly dry. For occasional use at stations, and especially for daily use by travellers and explorers, nothing can exceed the convenience and accuracy of the sling psychrometer, especially if the bulbs are protected from radiation by a slight covering of non-conducting material or even metal, as was done by Craig in 1866-69 for the stations of the U.S. Army Surgeon-General. The hair hygrometer gives directly the relative humidity or the ratio between the moisture in the air and that which it would contain if saturated. The very best forms perform very well for a time, but in general the instrument is not considered so trustworthy as the ventilated psychrometer.

The simple instrument for catching and measuring the quantity of rain, snow, or hail that falls upon a definite horizontal area consists essentially of a vertical cylinder and the measuring apparatus. The receiving mouth of the cylinder is usually terminated by a cone or funnel, so that the water running down through the funnel and stored in the cylinder is protected from evaporation or other loss. The cylinder is firmly attached to the ground or building, so that the mouth is held permanently at a definite altitude. The sources of error in its use are the spattering into it from the ground or neighbouring objects, and the loss due to the fact that, when the wind blows against the side of the cylinder, it produces eddies and currents that carry away drops that would otherwise fall into the mouth, and even carries out of the cylinder drops that have fallen into it. As a consequence all the ordinary rain-gauges catch and measure too little rainfall. The deficit increases with the strength of the wind, and the smallness or lightness of the raindrops and snowflakes. If we assume that the correct rainfall is given by a gauge whose mouth is flush with the level of the ground, and is surrounded by a trench wide enough to prevent any spatter, then, on the average of many years and numerous observations with ordinary rain-gauges in western Europe, and for the average character of the rain in that region and the average strength of the attending winds, the deficit of rain caught by a rain-gauge whose mouth is 1 metre above the ground is 6 per cent. of the proper amount; if its elevation is 1 foot above ground, the deficit will be $3\frac{1}{2}$ per cent. This deficit increases as the gauges are higher above the ground in proportion to the square root of the altitude, provided that they are fully exposed to the increase of wind that prevails at those altitudes. It is evident that even for altitudes of 5 or 10 feet the records become appreciably discrepant from those obtained at the surface of the ground. The following table shows in the last column the observed ratio between the catch of a gauge at any altitude and that of the standard at the level of the ground. Unfortunately, there is no record of the force of the wind to go with these measurements; but we know that in general, and on the average of many years corresponding with those here tabulated, the velocity of the wind increases very nearly as the square root of the altitude. Although this deficit with increasing altitude has been fully recognized for a century, yet no effort has been made until recent years to make a proper correction, or to eliminate this influence of the wind at the mouth of the gauge. Professor Joseph Henry, about 1850, recommended to the observers of the Smithsonian Institution the use of the "pit-gauge." About 1858 he recommended a so-called shielded gauge, namely—a simple cylindrical gauge 2 inches in diameter, having a wide horizontal sheet of metal like the rim of an inverted hat soldered to it. This would undoubtedly diminish the

Rain- and snow-gauge.

obnoxious currents of air around the mouth of the gauge, but the suggestion seems to have been overlooked by meteorologists. In 1878 Professor Nipher of St Louis, Missouri, constructed a much more efficient shield, consisting of an umbelliform screen of wire-cloth having about sixty-four meshes to the square inch. This shield seems to have completely annulled the splashing, and to have broken up the eddies and currents of wind. With Nipher's shielded gauges at different altitudes, or in different situations at the same altitude, the rain catch becomes very nearly uniform; but the shield is not especially good for snow, which piles up on the wire screen. Since 1885 numerous comparative observations have been made in Europe with the Nipher gauge, and with the "protected gauge" devised by Boernstein, who sought to prevent injurious eddies about the mouth of the gauge by erecting around it at a distance of 2 or 3 feet an open board fence with its top a little higher than the mouth of the gauge. The boards or slats are not close together, but apparently afford as good a protection as the shield of Professor Nipher.

In general it is now conceded by several high authorities that the measured rainfall must be corrected for the influence of the wind at the gauge, if the latter is not annulled by Nipher's or Boernstein's methods. A practicable method of measuring and allowing for the influence of the wind was explained by the writer in 1888 (see *Symons's Meteorological Magazine* for 1889, or the *U.S. Monthly Weather Review* for 1899). This method consists simply in establishing near each other several similar gauges at different heights above the ground, but in otherwise similar circumstances. On the assumption that for small elevations the diminution of the wind, like that of the rainfall, is very nearly in proportion to the square root of the altitude, the difference between the records for two different altitudes may be made the basis of a calculation which gives the correction to be applied to the record of the lower gauge, in order to obtain the rainfall that would have been caught if there were no wind. It is only when the rainfall has been properly corrected for the effect of the wind on the gauge that we

obtain numbers that are proper to serve for the purpose of determining the variation of the rainfall with altitude, locality, or time.

It has been common to consider that the rain-gauge cannot be properly used on ships at sea, owing to the rolling and pitching of the vessel, and the interference of masts and rigging; but if gauges are mounted on gimbals, so as to be as steady as the ordinary mariner's compass, their records will be of great importance. Experimental work of this sort was done by Mohn, and afterwards in 1882 by Professor Frank Waldo; but the most extensive inquiry has been that of Mr W. G. Black (see *Journal Manchester Geographical Society*, 1898, vol. xiv.), which satisfactorily demonstrates the practicability and importance of the marine rain-gauge.

The moisture in the atmosphere comes from the surface of the earth or ocean by evaporation, a process which goes on continually, replacing the moisture that is precipitated as rain, hail, snow, and dew, and maintaining the total quantity of the moisture in the atmosphere at a very uniform figure. The rate of evaporation depends on the temperature, the dryness, and the velocity of the wind. It is not so important to meteorologists to know where the moisture comes from as to know its amount in the atmosphere, and in fact no method has yet been devised for determining how much moisture is given up by any specific portion of the earth, or ocean, or forest. Our evaporimeters measure the quantity of moisture given off by a specific surface of water, but it is so difficult to maintain this water under the same conditions as obtain in nature that no conclusions can be safely deduced as to the actual evaporation from natural surfaces. The proper use of these evaporimeters is as integrating hygrometers, to give the average humidity of the air, the psychrometer giving the conditions prevailing at any moment. Among the many forms of evaporimeter the most convenient is that devised by Piche, which may be so constructed as to be exceedingly accurate. Careful comparisons between the Piche and the various forms of absolute evaporimeters were made by Professor Thomas Russell, and the results were published in the *U.S. Monthly Weather Review* for September 1888, pp. 235-239. By placing the Piche apparatus upon a large whirling machine he was able to show the effect of the wind upon the amount of evaporation. This important datum enabled him to explain the great differences recorded by the apparatus established at eighteen Weather Bureau stations; based upon these results, he prepared a table of relative evaporation within thermometer shelters at all stations. The actual evaporations from ground and water in the sunshine may run parallel to these, but cannot be accurately computed. It is probable that Professor Russell's computations are smaller than the evaporations from shallow bodies of water in the sunshine, but larger than for deep bodies, like the great lakes and for running rivers. The Piche evaporimeter consists essentially of a glass tube, whose upper end is closed hermetically, whereas the lower end is covered by a horizontal disc of bibulous paper, which is kept wet by absorption from the water in the tube. As the water evaporates its descent in the tube is observed, whence the volume evaporated in a unit of time becomes known. So long as the paper remains clean, and the water is pure, the records of the instrument depend entirely upon the evaporating surface, the dryness of the air, and the velocity of the wind.

The direction and apparent velocity of the motion of the clouds, or other objects floating above us, are best observed by means of the nephoscope, which has now become a necessary item in the outfit of any first-class

Evaporometer.

meteorological station. Among the various forms of this instrument are the so-called nephoscope of Fornioni, the marine nephoscope of Fineman, the simple mirror with attachments used by Clayton, the cloud camera of Vettin, and the alt-azimuths of Mohn and Lettry. The most perfect form for use on

equally convenient for observing the positions of auroras, halos, meteors, and other special phenomena. For the international work undertaken during the year 1898, the photographic camera established upon an alt-azimuth mounting, or the so-called photogram-meter, was especially developed. In this apparatus photo-

graphs of the clouds are taken simultaneously at two or more stations, and in each case the centre of the photographic plate has its altitude and azimuth determined. From this centre one can measure on the plate the additional angles required in order to fix the altitude and azimuth of any point that is photographed, and thus the dimensions of the whole visible cloud and its internal or differential motions can be determined, as well as its general motion. During the year 1898 about twenty stations were occupied throughout the world for the purpose of determining accurately the altitudes and motions of every layer of cloud.

The ordinary meteorological record specifies the proportion of sky that appears to be covered with cloud, or the so-called cloudiness, usually expressed in tenths. The observer generally confines his attention to that portion of the sky within sixty degrees of the zenith, and ignores the lower zone, since the clouds that are found therein are often at so great a distance from him that their record is not supposed to belong to his locality. As the cloudiness—or its reciprocal, the sunshine

Sunshine recorder.

Fig. 2.—Marvin's Nephoscope.

land is that devised by Professor Marvin in 1896 for the U.S. Weather Bureau stations (see Fig. 2); while the most convenient for use at sea is that used in 1889 by the author on the cruise of the *Pensacola*, and first described in the report of the International Meteorological Congress held at Chicago in August 1893.

The construction of this instrument is shown in Figs. 3, 4, 5. In using it the observer looks down upon a horizontal mirror and observes the reflection of the cloud. By moving his eye he brings any cloudy point into coincidence with the reflection of a small fixed spherical knob above the mirror, and keeps the images of the knob and the cloud coincident as they pass from the centre of the mirror to its edge. This line of motion shows the azimuth of the horizontal component of the cloud's motion. The apparent angular velocity of the cloud, as it would be if the cloud started from the zenith, is obtained by counting the seconds that elapse between its passage from the centre to the edge, or to a small circle inscribed within the edge. With this instrument two observers a short distance apart may easily determine the apparent altitude, and azimuth, and motion of any cloud, whence its true altitude and velocity may be computed. When the observer uses the marine nephoscope on a vessel which is itself in motion, he observes the resultant of his own and the cloud's motions. If his vessel is under his own control, so that he may change its velocity or direction at will, he easily determines this resultant for two cases, and obtains data by which he is enabled to calculate the real altitude and velocity of the cloud in terms of his own velocity. As the nephoscope can be used on a waggon moving rapidly over a smooth road, or in a small boat on a smooth pond, almost as well as on a larger sea-going vessel, it becomes an instrument of universal application for cloud study. It is also

—is supposed to be the most important item in agricultural climatology, and is certainly also important for dynamic meteorology, it is usually considered desirable to obtain more complete records than are given by only one or two specified hours of observation. To this end apparatus for recording sunshine, or, rather, the effect of cloudiness,

is supposed to be the most important item in agricultural climatology, and is certainly also important for dynamic meteorology, it is usually considered desirable to obtain more complete records than are given by only one or two specified hours of observation. To this end apparatus for recording sunshine, or, rather, the effect of cloudiness,

is widely adopted. At least three forms are worth describing.

The *Jordan photographic sunshine recorder* consists of a cylinder enclosing a sheet of sensitive paper; the sun's

intensity prevails, or was prevented by cloudiness. Mr D. T. Maring, in the *U.S. Monthly Weather Review* for 1897, described an ingenious combination of the thermometer and the photographic register of cloudiness, which is worthy of further development. It gives both the quantity of cloudiness and intensity of the sunshine on some arbitrary relative scale.

The intensity of the sunshine, as sometimes employed in general agricultural studies, is also shown by Violle's conjugate bulbs, which are thin copper balls about 3 inches in diameter, one of them being blackened on the outside and the other gilded. When exposed to the sunshine the difference in temperature of the two bulbs increases with the intensity of the sunshine, but as the difference is dependent to a considerable extent on the wind, the Violle bulbs have not found wide application. The Arago-Davy actinometer, or bright and black bulbs *in vacuo*, constitutes a decided improvement upon the Violle bulbs, in that the vacuous space surrounding the thermometers diminishes the effect of the wind. The physical theory involved in the use of this instrument was fully developed by Ferrel, and he was able to determine the coefficient of absorption of the earth's atmosphere and other data, thereby showing that this apparatus has considerable pretensions to accuracy. In using it as contemplated by the inventor and by Professor Ferrel, we read simply the stationary temperature recorded by the bright and black thermometers at

HORIZONTAL PROJECTION OF COMPASS.

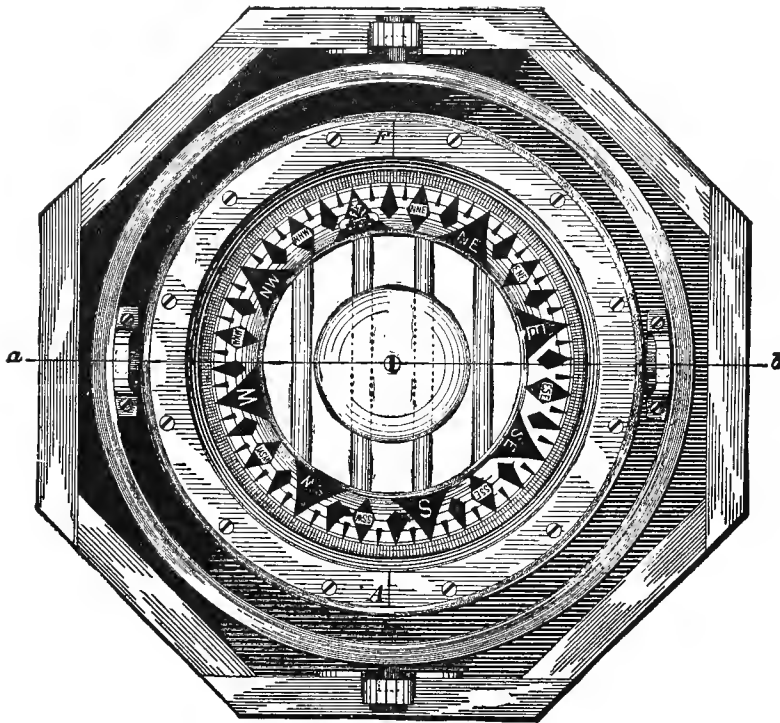

FIG. 4.—Marvin's Nephoscope.

rays penetrate through a small aperture, and describe a path from sunrise to sunset, which appears on this sheet after it has been properly washed with the fixing solution. Any interruption in this path, due to cloudiness or haze, is of course clearly shown, and gives at once the means of estimating what percentage of the day was clear and what cloudy. The form of the instrument constructed by Professor Marvin has been used for many years at about forty Weather Bureau stations, and the original construction is still employed by other observers throughout the world. The *Stokes-Campbell recorder* consists of a globe of glass acting as a burning-glass. A sheet of pasteboard or a block of wood at the rear receives the record, and the extent of the charring gives a crude measure of the percentage of full or strong sunshine. Many of these instruments are used at stations in Great Britain and the British colonies. The *Marvin thermometric sunshine recorder* consists of a thermometer tube, having a black bulb at the lower end and a bright bulb at the other. The excess of temperature in the black bulb causes a thread of mercury to move upwards, and for a certain standard difference of temperature of about 5° F., such as would be produced by the sun shining through a very thin cloud or haze, a record is made by an electric current. The record simply shows that during the day sunshine of a certain

any moment, whereas the best method in actinometry consists in alternately shading and exposing the apparatus so as to determine the total

SECTION ON LINE *ab*.

FIG. 5.—Marvin's Nephoscope.

effect of the solar radiation in one minute, or some shorter unit of time. This so-called dynamic, as distinguished from the static, method was first applied by Pouillet in 1838 in his use of his pyrheliometer, which was the first apparatus and method that gave

approximate measures of the radiation of heat from the sun. In order to improve upon Pouillet's work more delicate apparatus has been constructed, but the fundamental methods remain the same. Thus Ångström has applied both Langley's bolometer and his own still more sensitive thermoelectric couples and balance method, and Violle his absolute actinometer, consisting of a most delicate thermometer within a polished metal sphere, whose temperature is kept uniform by the flow of water, while Crova, with a thermometer within an enclosure of uniform temperature, claims to have attained an accuracy of one part in a thousand. Chwolson reviewed the whole subject of actinometry, and has shown the value of his own apparatus, consisting of two thin plates alternately exposed to and shielded from sunshine, whose differences of temperature are measured by electric methods.

As none of the absolute methods for determining the solar radiation in units of heat lend themselves to continuous registration, it is important to call attention to the possibility of accomplishing this by chemical methods. The best of these appears to be that devised by Marchand by the use of a device which he calls the Phot-antipimeter. In this the action of the sunlight upon a solution of ferric-oxalate and chloride of iron liberates carbonic acid gas, the amount of which can be measured either continuously or every hour; but in its present form the apparatus is affected by several serious sources of error.

The electric compensation pyrheliometer, as invented by Knut Ångström (*Ann. Phys.*, 1899), offers a simple method of determining accurately the quantity of heat received by radiation. He employs two blackened platinum surfaces, one of which receives the radiations to be measured, while the other is heated by electric current. The difference of temperature between the two discs is determined by a thermocouple, and they are supposed to receive the same amount of energy when their temperatures are the same. A Hefner lamp is used as an intermediate standard of radiation, and alternate observations on any other two sources of radiant heat give the means of determining their own relations to each other. By means of two such instruments observations were made simultaneously on the intensity of the solar radiation at two points, respectively 360 and 3352 metres above sea-level, to determine the amount of heat absorbed by the intermediate atmosphere. An accuracy of 1-1000 appears to be attainable.

The numerous forms of apparatus designed to keep frequent or continuous register of the prevailing pressure, temperature, moisture, wind, rainfall, sunshine, evaporation, and other phenomena are instruments that belong peculiarly to meteorology as distinguished from laboratory physics. The apparatus may be broadly divided into several classes according as the records are obtained by the help of photography, or electricity, or by direct mechanical action. The prevailing tendency at present is in favour of apparatus in which the work of the recording pen is done by a falling weight, whose action is timed and limited by the making and breaking of electric currents by the meteorological apparatus proper. The most serious defect in such instruments, even when kept in good working order, is a want of sensitiveness commensurate with the desired openness of scale. It is very important that a fraction of a minute of time should be recognizable, as also one-tenth of a degree of temperature; and one-thousandth of an inch of barometric pressure, and velocities of one hundred miles per hour, as well as rapid changes in all these elements, must be measurable. But instruments whose scales are large enough to record all these quantities are usually so sluggish

Meteoro-graph.

that the comparison of the records is very unsatisfactory. In order to study the relationships between temporary and fleeting phenomena, it is necessary that all instruments should record upon the same sheet of paper, so that the same time-scale will answer for all. The instruments that respond most nearly to the general needs of meteorology are the various forms of meteorographs devised by Wild for use at St Petersburg, by Sprung and Fuess for use at Hamburg and Berlin, and by Marvin for Washington. The photographic systems for pressure and temperature introduced many years ago at stations in Great Britain and the British colonies are not quite adequate to present needs. The portable apparatus manufactured by Richard Frères at Paris is in use at a very large number of land stations and on the ocean, and by giving special care to regular control-observations of time, pressure, and temperature, important results may be obtained; but in general the time-scales are too small, and the unknown sources of error too uncertain, to warrant implicit reliance upon the records.

The brightness of the sky light, and especially the amount of polarization, have been observed with increasing interest, as it seems possible from these two elements to ascertain something with regard to the condition and amount of the moisture of the air. With a simple Nicol's prism held in the hand and turned slowly about the axis of vision one can quickly recognize the fact that the sky light is polarized, and that the polarization is largely due to the air or dust lying between us and the clouds in the distant horizon. Arago with a more delicate form of polariscope determined the existence of a so-called neutral zone. Babinet located a neutral point or zone about as far from the anti-sun as was Arago's from the sun itself. Brewster discovered a neutral point near the sun and horizon, disappearing when the sun is more than 15° above the horizon. Finally, Brewster explored the sky sufficiently to draw lines of equal polarization, which he published in Johnston's *Physical Atlas*, and which were confirmed by Zantedeschi in 1849. Since those days far more delicate work has been done—first by Bosanquet of Oxford, afterwards by Professor Pickering of Harvard University and Professor Wright of Yale University. A later contribution to the subject is by Jensen (see *Met. Zeit.* for Oct.-Dec. 1899), who has observed the brightness as well as the polarization, and thus completed the data necessary for testing the various physical theories that have been proposed for the explanation of this phenomenon. We owe to Tyndall the capital discovery that when a beam of white light penetrates a mass of fine aqueous mist the latter sends off at right angles a delicate blue light, which is almost wholly polarized in a plane at right angles to the plane of reflection. As the particles of mist grow larger, the blue light becomes whiter and the polarization disappears. The original vapour particles are undoubtedly so small as to be comparable in size with a fraction of the wave-length of ordinary light, and Rayleigh was able to show that such minute particles must have a power of selection, and that the diffused sky light comes to us by selective reflection. On this basis we should expect that in the driest air at great heights, where the temperature is low and condensation has but just begun, and the dust particles are rare, there would occur the smallest aqueous particles, the feeblest intensity, and the largest amount of polarization. In his work on this subject (see *Phil. Mag.*, May 1899) Rayleigh has shown that it is quite possible that the atoms of oxygen and nitrogen constituting the atmosphere may themselves also exercise a diffuse selective reflection, and contribute to the brightness and polarization that are mainly due to aqueous vapour.

Photo-meter.

With these theoretical points in mind, we see the importance of adding photometry and polarimetry to the work of a meteorological observatory. The apparatus to be used in this connexion will vary somewhat with the exact character of the observations to be made. The most extensive researches that have yet been carried out in this line with a meteorological application in view are those of Jensen, Crova, Cornu, Pickering, and especially Rubenson, who in fact recommended that polarimetry and photometry should go hand in hand. In order to measure the position of the plane of polarization the Arago polariscope may be used, but, in order to measure the percentage of polarized light, Mascart's modification of the Savart is better. In order to measure the general brightness of a spot in the sky, Jensen has used a slight modification of the Weber photometer, and in fact Weber himself has applied the same method to the measurement of the daylight. The complete work of Jensen was published in the *Schriften* of the Scientific Association of Schleswig-Holstein in 1899, and, like the memoir published by Rubenson in 1863, it gives the meteorological conditions in full as a basis for the investigation of the connexion between sky light and the moisture in the atmosphere.

The cyanometer devised by Arago to measure the blueness of the sky consisted of an arbitrary scale of blues on a strip of porcelain, with which one could compare the blue of the sky. This comparison, however, is open to many subjective errors. A more satisfactory apparatus is Zollner's photometer or some equivalent, in which a patch of white surface is illuminated by any particular tint or combination that may be desired. In fact, Maxwell's colour-box admits of ready application to the analysis of sky light, and reveals at once the proportions of red, yellow, and blue that may be contained therein.

The importance of observing the dustiness of the atmosphere has been especially realized since the invention and use of various forms of apparatus for counting

Dust-counter.

the number of particles of dust in a small volume of air. These inventions are due to Mr John Aitken, of Edinburgh, and a short description of his results was presented by him to the Meteorological Congress in 1893 at Chicago. The latest form of his apparatus is very convenient, and is called the pocket dust-counter. In this the air contained in a small receiver is rendered dustless by repeated expansions, in each of which the cooling due to expansion forces the vapour to condense upon the dust, which, becoming heavy, falls to the bottom, so that in a short time all is removed. A small stop-cock is now turned, so as to allow a definite small quantity of air to enter and mix with the dustless air in the receiver. The natural and pure airs are now thoroughly mixed, and again the whole quantity within the receiver is expanded, and the dust nuclei fall down by the condensation of vapour upon them. Assuming that every particle of dust is represented by a minute droplet of water, we have but to count the latter; this is easily done by causing all the drops to fall upon a polished plate of black glass, which is divided into small squares by fine lines ruled with a diamond point. Usually each of these squares represents a small fraction of a cubic centimetre of air; thus in one case the number of fog particles averaged 2.6 per square millimetre of the glass plate, and, as the multiplying factor was 100, this corresponded to 260 particles of dust in a cubic centimetre of air. The purest air has been found in the West Highlands of Scotland, where 16 particles per cubic centimetre was once recorded as the minimum, while 7600 was the maximum. On the Rigi Kulm, in Switzerland, the purest air gave 210, and the dustiest 16,500. On comparing the records of the dust-counter with the record of the apparent state of the air, Mr Aitken found

that 500 particles per cubic centimetre corresponded to clear air, and 1900 to a thick haze in which distant mountain tops were hidden. In the cities the particles of soot and effluvia of all kinds act as dust, and both in London and Paris the numbers ran as high as 80, 116, 150, and 210 thousand per cubic centimetre.

The electrical phenomena of the atmosphere undoubtedly belong to meteorology, and yet the methods of observation have been so unsatisfactory and the difficulty of interpreting the results has been so baffling that regular observations in electricity are only carried out at a very few meteorological institutions. A general summary of our knowledge of the subject was prepared by J. Elster and H. Geitel for the International Congress held at Chicago in 1893, but the methods and apparatus of observation have not received any remarkable modifications. In general the water-dropping collector of Lord Kelvin, arranged for continuous record by Mascart, continues to be the best apparatus for continuous observation at any locality, and a portable form of this same apparatus is used by explorers and in special series of local observations. In order to explore the upper air the kite continues to be used, as was done by McAdie for the Weather Bureau in 1885 and by Weber at Kiel in 1889. The difference of potential between the upper and lower end of a long vertical wire hanging from a balloon has been measured up to considerable altitudes by Elster and Tuma. In general it is known that negative electricity must be present in the upper strata just as it is in the earth, while the intervening layer of air is positively electrified. The explanation of the origin of this condition of affairs is given in the recent researches of Professor J. J. Thomson (*Phil. Mag.*, December 1899), and his interpretation is almost identical with that now recognized by Elster (see *Terrestrial Magnetism*, January 1900, vol. iv. p. 213). According to these results, if positive and negative ions exist in the upper strata and are carried up with the ascending masses of moist air, then the condensation of the moisture must begin first on the negative ions, which are brought down eventually to the earth's surface; thus the earth receives its negative charge from the atmosphere, leaving a positive charge or an excess of positive ions in the middle air. The observations of atmospheric electricity consist essentially in determining the amount and character of the difference of potential between two points not very far distant from each other, as, for instance, the end of the pipe from which the water-drops are discharged, and the nearest point of the earth or buildings resting on the earth. The record has only an extremely local value, and the investigations of Professor Trowbridge, made in conjunction with the U.S. Weather Bureau in 1882-85, show that the differences vary so much with the winds, the time of day, and the situation of the water-dropper, that the mere comparison of records gives no correct idea of the general electrical relationships. It had been suggested that possibly daily telegrams of electric conditions and daily maps of equipotential curves over the North American continent would be of help in the forecasting of storms, but it was shown to be useless to attempt any such system until some uniform normal exposure could be devised. (See *ATMOSPHERIC ELECTRICITY AND ELECTRICITY*, V.)

The exploration of the upper atmosphere is to be regarded as the most important field of research at the present time, and the kite and the balloon enable observers and apparatus to be carried to considerable heights, though by no means so far as is desirable. The kite was first used by Alexander Wilson at or near Glasgow in 1749, and has since then been frequently used by English observers. The later revival of interest in the subject dates principally at least

Electrical apparatus.

Kites.

from the work done in England in 1882 by Archibald, who used the kite to carry up anemometers to very considerable heights, and thereby determined the relative movement of the air in the free atmosphere. In 1883

son, he left the further prosecution of this work to Mr Rotch, who has made this a prominent feature of the work at his observatory, having carried up meteorographs to the height of 12,000 feet by means of a series of kites flying in tandem. The officials of the U.S. Weather Bureau have developed an admirable cellular kite, invented by Hargrave of Australia, and Professor Marvin's works on the theory and construction of this form are well known. The general appearance of the Marvin or Weather Bureau kite, the reel and other apparatus that go with it, and the meteorograph it carries up, are shown in Figs. 6, 7, 8. The size ordinarily used carries about 68 square feet of supporting surface of muslin tightly stretched on a light wooden frame. The line, made of the best steel piano-wire, is wound and unwound from a reel which keeps an automatic record of the intensity and direction of the pull. The reeling in and out may be done either by hand or by a small gas-engine. The observer at the reel makes frequent records of the temperature, pressure, and wind, the apparent angular elevation of the kite, and the length of wire that is played

FIG. 6.—Marvin-Hargrave Kite, with Meteorograph in position.

Mr Alexander McAdie used the kite in his studies of atmospheric electricity, and the present writer proposed to use it for a complete exploration as to temperature, moisture, and wind; but Mr W. A. Eddy of New York

out. At the kite itself the Marvin meteorograph keeps a continuous record of the pressure, temperature, humidity, and velocity of the wind. The meteorograph with its aluminium case weighs about two pounds, and is so securely lashed behind the front cell of the kite that no accident has ever happened to one, although the kites sometimes break loose and settle to the ground in a broken country many miles away from the reel. On four occasions the line has been completely destroyed by slight discharges of lightning; but in no case has the kite, the observer, or

FIG. 7.—Marvin Kite Reel.

first forced it upon public attention, and accepted the suggestion of the present writer to employ it for meteorological work. Having flown his kites at Blue Hill, with the permission of Mr Rotch, and having carried up with them the self-registering apparatus devised by Mr Fergu-

son, he left the further prosecution of this work to Mr Rotch, who has made this a prominent feature of the work at his observatory, having carried up meteorographs to the height of 12,000 feet by means of a series of kites flying in tandem. The officials of the U.S. Weather Bureau have developed an admirable cellular kite, invented by Hargrave of Australia, and Professor Marvin's works on the theory and construction of this form are well known. The general appearance of the Marvin or Weather Bureau kite, the reel and other apparatus that go with it, and the meteorograph it carries up, are shown in Figs. 6, 7, 8. The size ordinarily used carries about 68 square feet of supporting surface of muslin tightly stretched on a light wooden frame. The line, made of the best steel piano-wire, is wound and unwound from a reel which keeps an automatic record of the intensity and direction of the pull. The reeling in and out may be done either by hand or by a small gas-engine. The observer at the reel makes frequent records of the temperature, pressure, and wind, the apparent angular elevation of the kite, and the length of wire that is played

out. At the kite itself the Marvin meteorograph keeps a continuous record of the pressure, temperature, humidity, and velocity of the wind. The meteorograph with its aluminium case weighs about two pounds, and is so securely lashed behind the front cell of the kite that no accident has ever happened to one, although the kites sometimes break loose and settle to the ground in a broken country many miles away from the reel. On four occasions the line has been completely destroyed by slight discharges of lightning; but in no case has the kite, the observer, or

on account of its great interest and importance, we quote the following from Dr Frankfield's bulletin and the summary in the U.S. Monthly Weather Review for September 1899:—

Mean Temperature Gradients in degrees Fahrenheit per 1000 feet from the ground up to the respective altitudes.

the reel been injured thereby. Of course, such flashes are preceded by numerous rapidly-increasing sparks of electricity from the lower end of the wire, which warn the observer of danger. During the six months from May to October 1898, seventeen kite stations were maintained by the U.S. Weather Bureau in the region of the lakes, the Upper Mississippi and the Lower Missouri valleys, in order to obtain data for the more thorough study of atmospheric conditions over this particular part of the country. During these months 1217 ascents were made, and as no

great height was attempted they were mostly under 7000 or 8000 feet. There was thus obtained a large amount of information relating to the air within a mile of the earth's surface. The general gradients of temperature,

and Biot at Paris in August and September of 1804. The next important ascent was that of Bixio and Barral in 1850 at Paris. The most remarkable high ascents have been those of James Glaisher, 2nd

Balloons.

September 1862, and Berson at Berlin in 1889; on both of these occasions the aeronauts attained altitudes of from 30,000 to 35,000 feet. Similar systematic ascents at many points in Europe simultaneously on pre-arranged dates have been made during the years 1895-99, and promise to be an important feature in the future study of the atmosphere. Owing to the great risk to human life in these high ascents, and especially to the fact that we desire records from still greater heights, efforts have been made to devise self-recording apparatus that may be sent up alone to the greatest heights attainable by free hydrogen balloons carrying the least possible amount of ballast. As these ascensions are made with great velocity, and therefore as nearly vertical as possible, they are called "soundings," because of their analogy to the mariner's usage at sea, and the balloon is called a "sounding balloon." Such balloon soundings have been made not only individually, but by pre-arranged system simultaneously in combination with the ascent of free-manned balloons above referred to; and at some places kites have been simultaneously used in order to obtain records for the lower atmosphere.

FIG. 8.—Marvin Kite Meteorograph.

which were promptly deduced and published by H. C. Frankenfield in 1899 in a bulletin of the Weather Bureau, gave for the first time in the history of meteorology trustworthy actual observations of air temperatures in the free atmosphere in numbers sufficient to indicate the normal condition of the air.

The kite and meteorograph have already been adopted for use by European meteorologists at Trappes, Hamburg, Brussels, Berlin, and Strasburg. Especially successful has been the work of Mr A. L. Rotch, the proprietor of the Blue Hill Observatory; and of Mons. Leon Teisserenc de Bort, the proprietor of the observatory for dynamic meteorology at Trappes.

The first experiments in simultaneous work were made in 1896 and in 1897, when ascents were made at eight or more points in France, Germany, and Russia.

FIG. 9.—Chart of Isotherms in Free Air above Trappes. This diagram shows the height at which the isotherms of 0°, -25°, -40°, -50° C. were encountered on the respective dates. Below the ground-line are given both the dates and the temperatures of the air observed at the ground when the balloon started on each ascent. The isotherms of -40° and -50° are not given for certain ascents, because in these the balloon did not rise high enough to encounter those temperatures.

The balloon was used for the scientific exploration of the atmosphere quite freely during the 19th century. The first important voyages were those of Gay-Lussac

and the discussions to which they gave rise have emphasized the importance of increasing the sensitiveness of the self-recording apparatus, and

as far as practicable the rapidity of the ventilation of the thermometers, and of providing more perfect protection against radiation from the sun or to the sky. It is believed that accurate records may be attained up to at least 30,000 metres, but as yet 20,000 has not been attained, and the records brought back are still under considerable criticism on account of instrumental defects. In general the wind that supports the kite also furnishes sufficient ventilation for the thermometer; but in the case of the sounding balloon, which as soon as it attains its summit-level (and its rapid rate of ascent diminishes) floats along horizontally in the full sunshine, a strong artificial ventilation must be provided. Moreover, the sluggishness of the best thermometers is such that during the rapid rise the records of temperature that are being made at any moment really belong to some altitude considerably below the balloon, and a most critical interpretation of the records is required.

The most enthusiastic work both with balloons and kites has been steadily pushed forward by Tiesserenc de Bort at Trappes; and from the results of about one hundred ascents during 1898-99, published by him in the *Comptes Rendus*, we quote the accompanying diagram (Fig. 9), showing the height at which the isotherms of 0° C., minus 25° C., minus 40° C., and minus 50° C. were encountered by the kites or balloons on the respective dates. As this diagram gives a fair picture of the conditions during the whole year—from April 1898 to July 1899—the present writer has deduced the average diminution with altitude, and the following table of results is quoted from the *U.S. Monthly Weather Review* for September 1899, p. 417:—

Average Diminution of Temperature in the Free Air above Trappes during 1898-99.

III. CLIMATOLOGY.

The climate of any locality is generally defined as the average condition in respect of atmospheric phenomena, meaning thereby not merely the general average of all values of the temperature, winds, rainfall, &c., but the extreme values and the averages of the extreme values for long periods of time. If we confined ourselves wholly to meteorology proper, we should necessarily define a climate by numbers and diagrams relating to these meteorological elements; but from time immemorial it has also been the custom to illustrate and even investigate climatic conditions by enumerating the plants and animals that flourish in different localities, and by tabulating the dates of sprouting, budding, leafing, fruiting, ripening, harvesting, and the dropping of the leaves. The study of plants from this point of view is called *phenology*; and in so far as plants depend upon the meteorological climate, it gives us a comprehensive view of both the present and the past climates of every portion of the earth since the ancient geological periods. But as the relations between plant life and meteorology are complex, and but little understood, we leave this field of study to the botanists and

palæontologists, and confine ourselves to the atmosphere proper. The most remarkable collection of data relative to phenology in its relation to meteorology is to be found in two essays by Dr Karl Linsser, published in 1864 and 1866 by the Imperial Academy of Sciences at St Petersburg. In these essays he has shown the nature of the dependence of the growth of the plant upon temperature, rainfall, the length and character of the growing season, and the latitude, and has given some important clues as to the natural process of the evolution of various species and varieties.

As to climatology proper, there are two classes of memoirs—those that confine themselves to numerical data, charts, and diagrams, and those that attempt by general descriptions to give a popular and vivid picture of the conditions that prevail in various localities. Of the latter we find an admirable illustration in Henry S. Blanford's work, *A Practical Guide to the Climates and Weather of India, Ceylon, and Burma, and the Storms of Indian Seas*, London, 1889. Of the works that combine both numerical tables and descriptive text, with a predilection in favour of the former, there is nothing to compare with the *Lehrbuch der Klimatologie* of Professor Hann, of which a second edition was published in 1897 in three volumes. But, in general, the climatological elements for any country, and especially for the whole world, can be well presented and comprehended by means of a few charts, and this is undoubtedly well done in Hann's *Atlas* of 1887, but most thoroughly in the third volume of Bartholomew's *Physical Atlas* (Constable and Company, London, 1899). This atlas of meteorology contains over four hundred maps illustrating the prominent features in the distribution of temperature, pressure, winds, clouds, sunshine, and rainfall, followed by a series illustrating storms and weather, which forms an admirable supplement to any textual presentation of the subject of meteorology. In the present article we shall only attempt some description of the general distribution and peculiarity of rainfall throughout the globe, taking advantage of the important memoir on this subject published by Supan in 1898, as "Supplementary volume No. 124 to *Petermann's Mitteilungen*."

The average condition of the atmosphere as to temperature and pressure over the whole globe is the climatological feature of fundamental interest for the student of theoretical meteorology. Professor Forbes was the first to attempt to define the relation between the mean temperature of any latitudinal zone and the mean ratio between the areas of land and water within that zone. His numerical determination of these ratios has been slightly changed by later authorities; but on account of the historical interest of the subject the following table is given, showing the temperatures, pressures, and ratios of land to water that served as the basis of important researches. The reader will perceive that the average temperature is decidedly affected by the presence of land; and the column of prevailing winds shows that these, as well as the barometric pressure, depend upon the temperature gradient, and therefore upon the presence of the land. In fact, in the study of the climate of a continent, the latter is considered as essentially the centre of a large area of disturbance in the midst of the ocean that covers four-fifths of the earth's surface. As we proceed from the shores of a continent inward we depart from the oceanic and approach the truly continental conditions. Ferrel has expressed these influences of land and water in a general formula, from which may be determined what the temperature and pressure would be if the earth were all land or water.

This subject has also been discussed by Forbes, Sartorius von Waltershausen, as well as Hann and Ferrel, and

the latest advance is found in the works of Zenker on "the distribution of heat and the fundamentals of climate." Formulæ representing the numerical relation between latitude and temperature or pressure on the one hand, and the ratio of land to water on the other, have been deduced. In the *Met. Zeit.* for January 1900 J. Liznar gives a slightly different treatment, somewhat as follows, of the questions discussed by Zenker and those who preceded him:—

The distribution of temperature on a hemisphere which is wholly land and wholly water can be deduced from a knowledge of the relative quantities of heat that fall upon the outer boundary of the atmosphere in different latitudes. Let this latter be indicated by I in arbitrary units; let the temperature of the surface of a land hemisphere be L, and that of a water hemisphere, W. Liznar gives the following formulæ connecting these qualities: $L = (I - 49) / 3395$ and $W = (I + 1208) / 5355$, and the temperatures computed by these formulæ are as follows:—

Lat.	L.	L.	W.	L - W.
0	3053	+ 33.7° C.	+ 27.7° C.	+ 8.0° C.
10	3011	32.6	24.9	+ 7.7
20	2886	29.3	22.7	+ 6.6
30	2683	23.8	19.0	+ 4.8
40	2412	15.8	13.7	+ 2.1
50	2038	+ 5.4	+ 7.1	- 1.7
60	1737	- 7.5	- 0.7	- 6.8
70	1446	- 19.7	- 7.6	- 12.1
80	1310	- 26.1	- 11.1	- 15.0
90	1267	- 28.3	- 12.2	- 16.1

From these figures for L and W we may compute the temperature of each zone of the earth's surface by taking into account the actual relation between land and water. The amount of land in any zone may be expressed as N, a fraction of the area of the zone,

and the amount of water will therefore be (I - N). Using the value of N, as measured by Dove, we obtain the computed temperatures (C) of the following table, and for comparison we add the observed mean annual temperatures (O), as deduced by Liznar from the measurements previously published by Spitaler and Batchelder, as shown in the following table:—

Latitude.	N. Land Area.	C. Temperature computed.	O. Temperature observed.
N. 70	0.543	- 14.1° C.	- 10.0° C.
60	.609	- 4.8	- 1.0
50	.587	+ 6.0	+ 5.6
40	.372	+ 14.4	14.0
30	.452	21.1	20.3
20	.315	24.8	25.2
10	.242	26.8	26.7
0	.216	27.4	26.2
- 10	.215	26.6	25.3
- 20	.235	24.3	23.0
- 30	.205	20.0	18.4
- 40	.041	13.8	+ 12.0
- 50	.019	+ 7.1	+ 5.6

Such studies, however, relate to an ideal earth and atmosphere, and have too little to do with the actual distribution of land and water, winds, temperature, and pressure in longitude, to justify their application to the real earth. Their results belong more properly to a globe whose surface is dotted with land and water, so uniformly intermixed that there can be no chance for the existence of distinct areas of continental and oceanic climates. We therefore hesitate to apply them to the elucidation of such climatic questions as that of the Glacial epoch and other problems suggested by geology.

The Distribution of Rain.—From a purely chronological point of view we have to consider the mean annual, seasonal, and monthly distribution of rain, and as a matter of less importance the diurnal distribution; we have also to consider the liability on the one hand to floods or excessive rains, and, on the other hand, to long periods of drought. From a geographical point of view we have to consider the rainfall both on the land and on the ocean, the increase or decrease of rainfall with altitude above the ocean, and the average variation of rainfall with the latitude of the place.

It has not been customary for observers on the ocean to keep records of the quantity of rain and snow, owing to the difficulty of finding a proper situation on the vessel for the rain-gauge, and also because of the supposed uncertainty of the observations themselves in adverse circumstances. Therefore, instead of the quantity of the rainfall, navigators have recorded only the time and duration of its occurrence and its general character as light or heavy, showery or steady. But even from these records it is possible to derive a rough approximation to the quantity, which is certainly more important than the mere duration, though both items serve scientific purposes. The depth of snowfall in inches is very important, as indicating the extent to which the soil and the roots of plants are kept warm during the winter season; but in the present text we consider only the equivalent depth of melted snow expressed in inches or millimetres of rainfall. Although twenty thousand stations are recording rainfall, only the records of perhaps five thousand are available for our study, because of the length of the individual series of observations; and these would not suffice as the basis of satisfactory general rainfall charts unless their indications were supplemented by a careful study of the shorter series, and especially of the general statements of explorers, agriculturists, and geographers as to the relation between wind and rainfall, and the results of general experience. The quantity of rain during the respective seasons of the year is very important from an agricultural point of view.

Up to a certain point the terms "wet" and "dry" as applied to a climate are entirely relative, and generally concern the influence of rainfall upon plant life. But the development of plants depends largely upon the character of the soil and its power to retain moisture during drought; it also depends upon the dryness of the air and the strength of the wind, and the consequent evaporation, and also upon the character of the precipitation, whether rain or snow, and therefore in part upon the temperature. However, we shall not go far wrong if we consider an annual rainfall of 250 millimetres as a dry climate, and one of 1000 millimetres or more, namely, 40 inches, as a wet one.

The isohyetal of 250 millimetres is the boundary of the Arctic basin on the north and the Antarctic on the south. Within these regions the undoubted deficiency in rain, added to the low temperature, forbids almost any form of vegetation. The greater part of Europe between latitudes north 35° and 65° has at least a moderate rainfall, namely, between 250 and 1000 mm.; the coast of Norway has two rainy regions, but the region east of the Scandinavian mountains shows a great falling-off. The British islands are more rainy and warmer than Scandinavia, and the contrast between the east and west sides of them is strongly marked, the contrast being due to the fact that the south-west winds laden with moisture from the Atlantic necessarily deposit more rain when they first strike the land and are driven upwards by its disturbing action. In the Bay of Biscay we find an increase of rainfall, which is heaviest along the north-western slope of the Serra da Estrella in central Portugal, though almost equally heavy rain falls on the higher mountain slopes in the interior of France. Throughout the region of the Mediterranean the western coasts have more rain than the eastern.

In general the heaviest precipitation occurs when the mountains are so disposed that moist air is rapidly forced up to a great height. The two regions having an average annual rainfall of over 4000 millimetres, or 160 inches, are located on the Dalmatian and Albanian coasts of the Mediterranean and in the north-eastern corner of India, where damp south-west winds are forced up over steep mountain gradients. It is quite possible that an equally heavy rain occurs on the north-east coast near the summits of the mountainous islands of the East Indies, as also on the mountain-tops of the lake region of Central Africa. Almost as heavy rains are found in the island of Jamaica, and especially in the upper portions of the valleys of the Orinoco and Amazon. In the interior of Europe, the higher portions of mountain slopes are rainy, although the low land near by may be relatively dry. In mountainous countries like Switzerland the greatest variety exists in the distribution of rain, and regions having the most opposite qualities in this respect often lie contiguous to each other. In northern Asia there is great uniformity in the quantity of rain, unless indeed our rainfall records are defective. From the Volga eastwards to the Lena the annual quantity averages between 500 and 750 millimetres, which may be called a moderate rainfall. In Manchuria and northern China the quantity is but little larger, and a decided increase is found only as we move south-eastwards along the coast of China, Korea, and

Siam, between latitudes N. 40° and N. 10°. Japan also belongs to this region of moderate rainfall; but Supan points out the fact that the island stations on the southern coast of China, on which light-houses are stationed, report decidedly less rain than the adjacent coast stations. He thinks that this is in agreement with the general principle that horizontal currents of air, such as the sea breezes, give no rain until they meet obstacles of considerable extent, such as the precipitous coast, when they begin to rise rapidly and cool, as in the ordinary process of rain-making. But the present writer would say that the study of rain-gauges exposed to severe winds on the east coast of the United States demonstrates that they catch less rain than they should, owing to the action of the wind at the mouth of the gauge. This effect of the wind at the gauge has undoubtedly influenced all records of rainfall in exposed situations, and plausibly explains the deficit just referred to. In the East Indian region British, and especially Dutch, meteorologists have made excellent rainfall records. In this region not only do land and water intermingle in fairly equivalent proportions, but the annual movement of the sun northwards and southwards, the annual changes of the monsoon, and the migration of the equatorial belt of calms, all combine to produce most decided seasonal variations in this rainy region. Thus, on the island of Luzon the easterly trade-winds cause an annual rainfall of 3000 millimetres on the eastward slope of the mountains, but the western side has only 1800. On the island of Sumatra, where the rain principally falls during the south-western monsoon, the south-western side has 4160 millimetres, but the north-eastern side 2700 millimetres; in the northern or peninsular part of the island of Celebes, which trends east and west, the northern slope has an annual rainfall of 2540, but the southern slope 1390 millimetres. In Hindustan the great south-west monsoon of the summer season is the rainy wind; hence the west or south-west coasts are generally rainier than the east coasts. This summer monsoon, when it reaches the head of the Bay of Bengal, divides into two branches; the main branch continues on to Burma and Siam, while the other turns to the north-west over the Ganges and along the south face of the Himalaya mountains. The rainiest station on the globe, Cherrapungi, lies in the midst of the main branch, and is also on the side of a moderate mountain; it is so situated that it seems to be exactly under the summit of the standing wave in the atmosphere due to the enforced flow of the monsoon over this mountain, like the waves on the surface of a stream of water flowing over a rocky bed. Doubtless the heavy rainfall at Cherrapungi is not experienced over a region of more than 10 square miles.

Among the regions that receive but little rain are some that are generally known as deserts, although there may be plenty of water stored away deep down in the soil. Thus on the western side of the Rocky Mountains and in the so-called plateau region, as also on the eastern slope farther southwards, and among the Andes in South America, are narrow zones containing many regions of small rainfalls. In Europe and Asia there are several such regions. Thus on the northern border of the Tian Shan is a large area whose annual rainfall is from 400 to 600 millimetres; but as we pass inwards to the desert of Gobi we come to small regions of less than 200 millimetres, such as we also find when we go far northwards over the Kirghiz Steppes. In general the regions of small rainfall are on the leeward sides of mountain ranges or in valleys and plateaux between such ranges. The great south-western monsoon that brings so much rain to southern India brings dryness to the interior of Asia; thus, at Leh in the valley of the Upper Indus the annual rainfall is less than 80 millimetres, and the snow-line is at a level of about 19,000 feet. Similar dry valleys occur in the Rocky Mountain region and the Andes, and several are known in Switzerland.

In both Africa and South America the interesting feature of the rainfall is the great extent and importance of the region of equatorial rains. In Africa this is bounded on the north by the light rain of the Sahara Desert and on the south by the almost equally light rains of the various South African states and colonies. Between these—namely, between latitudes N. 15° and S. 15°—is the region of heavy rain that supports such rivers as the Zambezi, the Congo, the Niger, and the Nile. Over the basins of each of these rivers the general average rainfall is about 1500 millimetres. The heaviest rains of Africa occur on the west coast, especially on the Gulf of Guinea, and from Sierra Leone to the Gold Coast. On the oceanic side of Cameroon mountains there appears to be a remarkable rainfall, but the report of over 9000 millimetres per year at Debnndji (latitude N. 4°, longitude E. 9°) has every appearance of being a numerical error on the part of the observer. The rainfall at all points on the coast of Africa is of the monsoon type—that is to say, it has a regular annual period; but of course the periods vary for the regions within and beyond the equatorial zone. Even the rainfall in the great African lake region has a monsoon character, being largely dependent upon the south-eastern monsoon from the South Indian Ocean, which, after striking the African coast, is during the northern summer deflected northwards, and not only crosses the equator, but becomes the south-western monsoon of India and China.

In Australia the distribution of rain is very sharply marked. The whole interior of this continent lies under the influence of the tropical belt of light rain, and is subject to severe droughts. On the south-western coast the south-eastern trade-winds penetrate sufficiently to give a considerable region a rainfall of 1000 millimetres annually, mostly in June, July, and August. At the opposite season of the year the north and north-eastern sides of the continent receive rather a large amount coming from the equatorial belt of rains, which then extend south of the equator. The eastern side of Australia receives a moderate amount, but over a larger area, from the south-eastern trades which in the summer season blow with increased force against this coast and cause abundant rain on the higher mountains. The western coast and interior of Australia receive on the average less than 250 millimetres, and are classed as desert, although artesian wells frequently bring up a copious supply of water from the reservoirs below.

In North America certain very dry regions known as the Rio Grande and Colorado deserts in the United States, and in South America the drier portions of Argentina and Peru, probably have about the same annual rainfall, viz., 100 to 200 millimetres. As we depart from these regions, either towards the equator or towards the Atlantic and Pacific Oceans, we come upon others that have more rain, the maximum being over 2000 millimetres on the southern and western coast of Alaska, and the western coast of Chile and Patagonia, and over a large region drained by the Amazon and Madeira rivers in Brazil. In the United States, those states bordering on the Atlantic and the Gulf of Mexico, from Louisiana to Newfoundland, have about the same rainfall as the interior of Siam and southern China.

Seasonal Rainfall.—The distribution of rain according to months and seasons, including periods of drought and flood, is quite as important as the amount of rainfall. In order to express in a few words the seasonal changes at all places on the globe, which have such great variety as to seem purely local in their character, we may perhaps deduce them all from a few general rules which should enable one to anticipate what the character of the rain must be at any place. In general, any cause that makes the air near the ground or ocean ascend rather rapidly will produce rain in proportion to the quantity of air that ascends, the quantity of moisture in the air, and the quickness with which the moisture condenses into cloud and rain. The last element, quickness, is approximately inverse to the height to which the air must ascend before becoming cloudy, and therefore inverse to the altitude of the lowest cloud surface. In general the north-eastern and south-eastern trade-winds of the northern and southern hemispheres, blowing towards the equator, combine with the intense action of the sun's heat to favour the formation of ascending currents and an equatorial rainy belt on the ocean without the special assistance of mountains or precipitous coasts. These oceanic equatorial rainy belts are very much displaced and distorted by the action of the continents and the larger islands. In this way is brought about the heavy rain over a wide area in Brazil, Central Africa, and the East Indian archipelago. Whatever causes the currents of air to descend retards or prevents the formation of cloud and rain, except in so far as the descent and dryness in one place must be accompanied by a corresponding ascent and rain in some other locality; thus the great south-western monsoon of India ascends and deposits rain on the southern side of the Himalaya, but, in so far as it descends on

the northern side, it brings extremely dry weather to Tibet, Turkestan, and Mongolia. Similarly, the strong westerly winds that ascend and form rain on the Alaskan and Patagonian coasts descend as dry air on the eastern slope of the Rocky Mountains and the Andes respectively.

Wherever great irregularities are absent from the earth's surface, as over the oceans and the plains, the ascending currents needed to form rain may be produced by the heating of the atmosphere near the soil under the influence of direct sunshine; but in some cases the same result is apparently produced by changes in barometric pressure going on in the upper layers of the atmosphere. These changes have been likened to great waves or billows in the atmosphere extending over large areas, and producing different effects according to the nature of the surface beneath them. When the trough by relieving the pressure over a large region of the lower air allows it to expand and cool, clouds may form and develop into a storm; the ascending air occurs primarily on the eastern side of the lowest pressure, and the rainfall accompanies it. In great contrast to the south-eastern trades of the southern hemisphere and the north-eastern trades of the northern are the anti-trades that prevail in the atmosphere a short distance above them, and that blow from the north-west and south-west respectively. These anti-trades may possibly have a slight descending tendency, and would therefore not form cloud and rain; but they are boisterous winds full of eddies, and therefore affect the trade-winds below them in such a way as to give rise to innumerable local rains and gusts. Moreover, when they eventually reach the surface of the ocean they strike the first coast that they meet, such as that of Great Britain or the Scandinavian peninsula, or Alaska, or southern Chile, and with great force are pushed upwards, giving plenty of cloud and rain. In the interior of Russia, Siberia, Australia, and North America the principal sources of local rains are the local eddies caused either by the heating of the ground in the sunshine or by the action of the strong winds overhead.

Over the ocean the regular migration of the trade-winds and equatorial zone northwards and southwards annually with the sun produces a regularity in the seasonal distribution of rain, according to the zones of latitude, which is expressed by Supan in the following table:—

Zone.	Limiting Latitudes.
I. Little rain in summer . . .	40° N. 27° N.
II. " " at all seasons . . .	27° N. 19° N.
III. " " in winter . . .	19° N. 7° N.
IV. Abundant rain at all seasons . . .	7° N. 1° N.
V. Little rain in winter . . .	1° N. 17° S.
VI. " " at all seasons . . .	17° S. 30° S.
VII. " " in summer . . .	30° S. 35° S.

These belts of dryness and rain are strongly marked on the windward coasts of the continents; they do not extend far inland, and are not clearly defined on the leeward coasts. As the winds are from either the north-east or south-east, the rainy regions must be on the easterly coasts. The changes in these belts depend on the changes of the wind, or what is frequently called the general circulation of the atmosphere; this latter is associated with the sub-tropical areas of high and low pressure, which shift their positions in summer and winter, about as shown by Supan in the following table:—

Maximum Pressure over	Winter Season.			Summer Season.			Semi-annual Movement, Winter to Summer.	
	Date.	Latitude.	Longitude.	Date.	Latitude.	Longitude.	Latitude.	Longitude.
North Atlantic .	Jan. 15	28° N.	44° W.	July 15	36° N.	34° W.	8° N.	1° E.
North Pacific .	Jan. 15	30° N.	138° W.	July 15	39° N.	147° W.	9° N.	9° W.
South Atlantic .	July 15	27½° S.	16° W.	Jan. 15	30° S.	4° W.	2½° S.	12° E.
South Indian .	July 15	31° S.	67° E.	Jan. 15	37° S.	91° E.	6° S.	24° E.
South Pacific .	July 15	34° S.	94° W.	Jan. 15	35° S.	104° W.	1° S.	10° W.

The general systematic movement of these areas northwards and southwards with the sun is better marked in the northern hemisphere than in the southern, undoubtedly owing to the larger percentage of land in the northern hemisphere, and the resulting contrasts between the temperatures and the resistances to motion over the land and water. In general, during the days and seasons when the barometric pressure is above the average for any region or season little or no rain falls therein.

The fundamental principle that rain falls only when there is a rapidly ascending moist current usually explains in a simple manner all the peculiarities of its geographical and chronological distribution. On the borders of areas of high pressure and within the areas of low pressure the air is ascending, but within the high areas it is descending. Hence the latter are dry and have a clear sky, but the former have cloudy skies and rain. As the sun moves north or south, returning to his first position within a year, so do the systems of winds and the regions of rain. Notwithstanding

the irregularities of local rainfall, the average of the rain on the land areas in any whole zone around the globe gives fairly homogeneous results. Such zones were first calculated by Murray (see *Scottish Geographical Magazine*, 1887, page 65) on the basis of the charts and data published by Loomis in 1882, and such zonal averages are embodied in the last column of the climatological table already given, where they can be compared with the mean annual temperature and pressure, but especially with the cloudiness and the ratio of the land and water. The large precipitation between 60° S. and 90° S., as compared with that between 60° N. and 90° N., is undoubtedly due to the presence of the Antarctic Ocean, which furnishes the moisture, and especially to the rapid westerly winds, which, by their action on the waves, and ice, and occasional islands, cause a sufficient vertical circulation to determine the formation of cloud, and rain, or snow. In general, the excessive precipitation in the equatorial regions both north and south must be ascribed to the abundant moisture in the air, and to

the rapid vertical circulation in the daytime, due to the action of the sunshine at the surface of the land and water, and especially to the character of the prevailing winds, which, by blowing from the north-east and south-east, must generally produce ascending currents in that region, except, possibly, in a few districts where they may glide past each other horizontally. In the Indian Ocean during the monsoon season the rainfall on the equator is not particularly large, owing to the absence of islands or opposing currents of air, and to the fact that the air of the south-western monsoon, having come rapidly from cooler regions to the south, has become warmed without being saturated, and has not yet attained the condition to form abundant rain. The hypothesis that any considerable quantity of air from either trade-wind region ever crosses the equator to the opposite region was considered untenable until John Eliot, director of the Meteorological Service for India, by means of his monsoon charts of the Indian Ocean, demonstrated that in the northern summer season the heated air over the eastern continent produces such a great disturbance of the ideal symmetrical system of trade-winds that the south-easterly trades of the southern Indian Ocean are drawn northwards, becoming southerly winds at the equator and south-westerly winds over the Persian Gulf, Hindustan, and the Bay of Bengal, while the feebler south-easterly trades north of Australia become the south-westerly winds of Siam and China. On the western continent, by a similar but feebler action, the north-eastern trades of the Gulf of Mexico become the south-eastern winds of a mild monsoon on the northern coast of the gulf; but owing to the small extent of the heated and elevated portion of the North American continent, this produces only monsoon rains in the valley of the Rio Grande, and has but slight influence apparently in disturbing the condition of affairs south of the equator in Brazil and Venezuela. In general, in both hemispheres, the amount of rain in the respective summers exceeds that in the winters; the summer rains are also more uniformly distributed over the general surface of the country, being, in fact, due to a special local action of the solar radiation, and not to the general action that produces the trade-winds and the monsoons. Rapidly ascending currents, and therefore cumulus clouds, may be formed either by the direct action of the solar heat or by the action of the wind upon obstacles at the earth's surface; the solar action produces the local summer rains, but both solar action and the obstacles to the wind contribute to produce the rains that attend the general monsoon winds. Condensation within a cloud, and especially that due to radiation from its upper surface, may be wholly counteracted by strong sunshine during the daytime if there be no supply of moist air to maintain the cloud, and, on the other hand, be greatly favoured by the absence of sunshine and by unobstructed radiation during night-time; in this way are explained the maxima of rain and cloud at 3 or 4 P.M., and about the same time in the early morning. On hot days, and within the tropics, one may see a growing cumulus cloud with its flat lower surface suddenly begin to expand at the top and rise so rapidly as to show that there is not a sufficient supply of moisture from below to maintain the flat base, whereupon the cloud assumes a balloon shape, larger at the top and tapering toward the bottom, and, becoming thinner and whiter, rises until it enters a stratum of overflow, where it is at once drawn out into a thin horizontal sheet of alto-cumulus or alto-stratus. This process may be again repeated, converting the alto-cumulus into cirrus, so that the same particles of moisture may appear successively as cumulus, alto-cumulus, and cirro-cumulus, and finally attain to the level of the most delicate cirrus cloud within a horizontal distance of one or two hundred miles. When this process is going on the rain falls from cumulus, if at all, and the cirri floating far in advance announce the presence of the distant storm. The supply of moisture for rain comes ultimately from the oceans; but the evaporation of this rain after it has fallen to the ground, and the repetition of precipitation and evaporation farther inland, form important steps in the distribution of this oceanic moisture. The wind that blows steadily until it has penetrated to the interior of the continent becomes drier because of its loss of moisture and its increase of temperature. It can only deposit rain when additions are made to its vapour by evaporation from the land or by mixture with moister air, but even then it must be cooled still further by higher ascensions and stronger radiations. In general the winter rains are due to a lower layer of moist air flowing from surfaces of warmer water inwards, sometimes to great distances over the continent, and at the same time rising slowly. The moisture for the summer rains comes from local evaporation and more rapidly rising currents, produced by the heat of the warmer part of the day. Therefore the diminution of rainfall as we pass from the coast to the interior is, relatively speaking, more decided in the winter season than in the summer. Supan gives a formula for this relation between the rainfall over the ocean and the land at different seasons and in different zones of latitude. Let L represent the aqueous vapour added to the atmosphere over the land, M the aqueous vapour carried by the winds from the ocean to the land, and K the efficiency of the conditions that favour condensation and rain; then in general we may have the rainfall

upon the land represented by the formula $(L + M)K$. This formula applies, for instance, to the west coasts of Europe and Canada, to the Asiatic and Australian monsoon regions. The various types of rainfall over the globe can be fairly represented by varying the three terms; for instance, in Egypt, especially in the delta of the Nile, the evaporation during the season of inundation is very large and the ocean breeze is also very strong, so that both L and M are large, but the conditions that favour the production of rain are so slight that K is practically zero, and therefore the rainfall is zero. In the polar zone L is nearly zero. In the temperate zone, as, for instance, over the continent of Europe and Asia, these conditions vary with the seasons. Thus in winter L is zero, but in summer L and M are both appreciable; in fact, L may be greater than M on the coast and M may be zero in the interior. In the sub-tropical rain zone L is small in winter, but in summer both L and M become large, while K becomes small and the rainfall may become zero. In the tropical zone L is always appreciable, and probably larger in summer than in winter. In the equatorial zone, on account of the light winds, M is inappreciable; but for coasts on which the trade-winds blow, L, M, and K are all appreciable.

Among the rainfall types are the following, in which it will be noticed that the distinguishing feature is not the geographical distribution, but the seasonal features or chronological distribution:—

(a) Permanently rainy regions, where 60 millimetres or 2.4 inches of rain or more falls during each season of the year. Such regions are found in general on the windward coasts of the continents, on the east coasts within the trade-wind region; also in the equatorial zone.

(b) Permanently dry regions, where less than 60 millimetres falls during each season of the year. Such regions may be found in the Arctic zones, the central portions of the continents of Asia and North America, the sub-tropical region on the west coasts of Africa and South America, the Sahara in northern Africa, and the Mohave Desert in Arizona.

(c) The variable rainy regions, where over 60 millimetres falls in certain special seasons.

(d) The variable dry regions, where less than 60 millimetres falls in special seasons.

Distribution of Rainfall with Altitude.—In the interior of an island or continent the increasing height of the land usually brings an increasing disturbance of the general currents of air that produce rain in mountainous regions; and although the wind may be too dry to produce rain over the low lands, yet it falls upon the high lands. We may thus, as we ascend within a continent, attain an elevation of nearly uniform rainfall throughout winter and summer, while the low land receives local summer rain, but little or no winter rain. On the island of Ascension the steady north-easterly trade-winds bring to the summit of Green Mountain uniform temperature, moisture, and rainfall, with an exquisite flora, while the lower flat portion of the island is almost rainless, subject to great evaporation, and destitute of plants. In Saxony and the Harz Mountains the general rainfall, according to Schreiber's *Klimatographie*, 1893, is distributed in altitude as follows:—

Altitude. Metres.	Absolute Rainfalls.			Relative Rainfalls.	
	Winter.	Summer.	Annual.	Winter.	Summer.
	mm.	mm.	mm.	Per cent.	Per cent.
100	221	351	572	38	62
300	280	398	678	41	59
500	337	444	781	43	57
700	396	490	886	45	55
900	454	536	990	46	54
1200	540	606	1146	47	53

Evidently, at some slightly higher elevation than 1200 metres, the winter and summer rainfalls would become equal. Above this elevation it is quite possible that the rainy and dry seasons would be reversed. Such inversion is known to occur on the summits of some high mountains and over some lofty plateau regions. The winds change with the seasons, but the rainfall depends upon the windward and leeward aspects of the wind relative to the mountains, and also on its dryness and its velocity, so that the altitude of the region of uniform annual distribution of rainfall has not yet been expressed by any simple rule. Not to go into too many details as to the numerous types of rainfall that have been described by Hann, Supan, and other climatologists, we may at least give the following interesting table by Supan, illustrating the features that most affect plant life and animal life, namely, the distribution of rainfall through the year according to three types:—(1) where the mean variability of rainfall is less than 10 per cent., so that the rainfall is uniform throughout the year; (2) where the mean variability lies between 10 and 19 per cent. inclusive, so that the rainfall may be said to have a very moderate periodicity; (3) where the rainfall has a mean variability of over 20 per cent. and shows a decided periodicity.

Distribution of Rainfall during the Year.

Year .	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0	100.0

In general the annual quantity of rainfall increases with the frequency with which rain falls; and we may also add that the annual quantity is in the inverse ratio to the annual variability, other conditions remaining the same, especially the geographical latitude.

Secular Change of Climate.—Geological study shows that the present distribution of rain, both geographical and chronological, did not prevail throughout the past history of the earth, but that the rainfall, snowfall, and fog or cloudiness have varied greatly as to place and time. The preceding tables and the text connected therewith show that these changes may easily have depended solely on corresponding great changes in the elevation of the continents, on the variations in their extent, and the distribution of land in latitude. On the other hand, the changes that have taken place within the past 3000 years—that is to say, since we have any historical or observational data—have been so small as to elude demonstration. A most careful comparison of the present climate with that prevailing during the earliest times in Greece and Asia Minor was published in 1898 by Eginitis, director of the observatory at Athens, from which we can only infer that there is no apparent difference in the climate, properly so called; and that if there be any difference in the flora and fauna, it must be due to a change in the latter produced by human interference or natural evolutions, but not by any change in climate.

Artificial Production or Prevention of Rain.—From time immemorial there have been those who believed that in some way or other man can influence the weather so as to avert disaster from droughts or storms. Even now this idea has a strong hold upon some who have not properly studied the advance of our knowledge in regard to the laws of nature. The matter would hardly be worthy of serious mention in this place were it not that there is abundant evidence that many are deceived and much money wasted by the so-called rain-makers and others. It is perfectly safe to maintain the general proposition that man cannot make any important change in the weather by means of noises, explosions, liberation of gases, erection of lightning rods, or any other device that has yet been suggested. We may learn to take advantage of the rain and the wind, or to defend ourselves from the lightning, the flood, and the storm, but we cannot alter them. Even in the case of the destruction of extensive forests and equally extensive reforestation, it has been satisfactorily shown that the measured quantity of rainfall is the same both with and without the forest, and both before and after its destruction; the numbers of local storms of wind are also the same, but the temperature near the ground and the evaporation from the surface of the ground are changed, so that the so-called climate within a forest is slightly different from that prevailing in an adjacent clearing. This is also true if we cover a piece of land with a house—the climate within the house is different from that outside; but these are plays upon the word climate and not meteorological changes properly so called. In Italy, Austria, and France a widespread delusion prevails as to the possibility of preventing hail by the bombardment of the clouds, analogous to the short-lived delusion promoted by Dyrenforth in the United States, to the effect that rain could be brought down by bombarding the clouds.

IV. PHYSICAL AND THEORETICAL METEOROLOGY.

The ultimate aim of those who are devoted to any branch of science is to penetrate beyond the phenomena observed on the surface to their ultimate causes, and to reduce the whole complex of observations and empirical rules based upon limited experiences to a simple deductive system in

which the phenomena observed shall be shown to flow naturally from the few simple laws that underlie the structure of the universe. A correct "theoria" or physical and logical argumentation deducing from primary laws all the phenomena constitutes the noblest achievement of man in science. It is by such works that Newton and Laplace distinguished themselves in astronomy. The development of the true physical and mechanical theories of atmospheric phenomena has made great progress, but is still inferior in completeness to astronomical work, owing to the great complexity of the meteorological problems. The optical and the thermal phenomena have been very satisfactorily elucidated, but the phenomena of motion or aerodynamics have only been elucidated to a limited extent, while the electrical phenomena have as yet no firm basis of explanation. We must, however, introduce the reader to some of the works that have been published on the subject, in the hope that thereby he will himself be persuaded to further study and induced to contribute to our knowledge.

Between the years 1853 and 1861 Professor William Ferrel published in *Gould's Astronomical Journal*, *Runkle's Mathematical Monthly*, and the *American Journal of Science* several treatises on the motions of solids and fluids relative to the earth's surface. His work resulted in the elucidation of the problems of the atmosphere, and in ingenious ways, applicable approximately to such complex cases, and analytically equivalent to the arithmetical method of quadratures or the graphic methods of geometry, he deduced important relations between the density of the air, the barometric pressure, and the attending winds. His essays seemed to show that it might be possible to treat the complex problems of meteorology logically and deductively by analytical, numerical, and graphic processes, and his memoirs were the first in which observed average meteorological conditions were properly coordinated with the fundamental formulæ of mechanics. Ferrel's ideas were made the basis of the system of daily weather predictions published by the present writer in 1869 in the *Bulletin of the Cincinnati Observatory*. This work was taken up by the Government, and greatly enlarged during 1871–91 by the chief signal officers of the army, and during subsequent years by the chiefs of the U.S. Weather Bureau. His works appear to have first attracted the attention of European mathematicians in consequence of reviews published by Hann in the *Zeitschrift* of the Austrian Meteorological Society in January 1875, but especially after they had been reprinted in a convenient form by the U.S. Signal Office as "Bulletin No. VIII." In 1881 Ferrel, after finishing his works on the tides for the U.S. Coast and Geodetic Survey, began a new and extensive series of meteorological contributions, three of which were published by the U.S. Coast Survey and the rest by the Signal Office. Stimulated by Ferrel's work, by the urgent needs of the modern weather bureaux throughout the world, and by the beauty of the mathematical problems presented, numerous mathematicians have lately taken up the study of the earth's atmosphere, so that the literature of the subject is now far more extensive than is generally supposed.

In addition to the purely mechanical problems, the numerous physical problems have also been carefully treated, both experimentally and mathematically. The problems of radiation have been elucidated by Langley, Hutchins, Ångström, Paschen, Violle, Maurer, Crova, Chwolson, and Very. The problems of thermo-

dynamics have been especially developed by Kelvin, Hertz, von Bezold, Ferrel, and Brillouin. The physical problems involved in the formation of rain-drops have been studied by an optical method by Carl Barus; and with brilliant success, from an electrical point of view, by C. T. R. Wilson and J. J. Thomson at the Cavendish Laboratory, Cambridge, England.

In a complete study of the mechanics of the earth's atmosphere we naturally begin by expressing in simple analytic formulae all the various conditions and laws according to which every particle of the air must move. Some of these are local matters, depending upon the resistances at various points of the earth's surface; others are of the nature of discontinuous functions, as, for instance, when the ascent of moist air above a certain level suddenly gives rise to condensation and clouds, to the evolution of latent heat, to the precipitation of rain, to the shading of the air and the ground below the clouds, and to the sudden interception of all the solar heat at the upper surface of the cloud. It seems, therefore, incredible that the problems of the atmosphere can ever be resolved by purely analytical methods; there must be devised combinations of numerical and graphical, and possibly even mechanical, methods to reproduce the problems and give us special solutions adapted to particular cases. But even these special methods can only be perfected in proportion as we attain approximate solutions of the simpler problems, and it is in this preliminary work that a good beginning has already been made, thanks to the homologies between the mathematics of hydrodynamics and of electricity.

The present state of theoretical meteorology, in which are included both physical and mechanical, cannot be fully presented in non-technical English text. It is imperatively necessary to employ algebraic formulae, or numerical tables, or graphic diagrams, the former being certainly the least cumbersome and the most generally available. The uniform system of notation devised by Professor F. H. Bigelow, of the U.S. Weather Bureau, is presented in the following lines taken from the *U.S. Monthly Weather Review* for May 1897:—

Professor Bigelow's notation is: R, radius of earth; r, any distance from the centre of the earth; θ , north polar distance; ϕ , north latitude; λ , east longitude; and $V = +\frac{m}{r}$, the potential; the positive normal is drawn from the surface outwards and the rotation is positive when right-handed, with translation along the positive direction. It is held by Professor Bigelow that terrestrial magnetism and meteorology must conform to these three last conventions, which have been uniformly adopted in modern physics. Developing the angle θ from the north pole and the angle λ towards the east, and the radius r towards the zenith, the system of co-ordinate becomes x positive towards the south, y positive towards the east, and z positive towards zenith. The corresponding velocities are u, v, w ; the corresponding accelerations, $du/dt, dv/dt, dw/dt$. Further details as to his notation and a very complete summary of the formulae of physical meteorology expressing the results of nearly all recent students will be found in chapters x. and xi. of Professor Bigelow's Report on the International Cloud Observations, published as vol. ii. of the annual report of the chief of the U.S. Weather Bureau for 1898-99.

The fundamental laws to which the atmosphere is subject are as follows:—

A. *The Equation of Elastic Pressure.*—The pressure shown and measured by the barometer is an elastic pressure acting in all directions equally at the point where it is measured. By virtue of this elastic pressure a unit volume of air will expand in all directions if not rigidly enclosed, but will cool in so doing. On the other hand, if forcibly compressed within smaller dimensions, it will become warmer. For a given temperature and pressure a unit volume of air of a prescribed chemical constitution will have a prescribed definite weight. The general relations between absolute temperature, pressure, and volume are expressed by the formula

$$pv = RT \quad \dots \quad (1)$$

where T expresses the absolute temperature, p the elastic pressure, v the volume, and R is a constant which differs for each gas, being 29.2713 for ordinary pure dry air and 47.060 for pure aqueous vapour, if we use as fundamental units the kilogram, metre, and centigrade degree. This equation is sometimes called the law of Boyle and Charles; it is also known as the equation of condition for true gases, meaning thereby that it expresses the fact that a true gas would change its volume directly in proportion to its absolute temperature and inversely in proportion to its elastic pressure. All gases depart from this law in proportion as they

approach the vaporous condition on the one hand, which is brought about by great pressure and low temperature, or the ultra-gaseous condition on the other hand, which obtains under high temperatures and low pressures. The more accurate law of Van der Waals would have no advantage in meteorological work. In place of the absolute temperature T we may substitute the expression $273^\circ \text{C.} \times (1 + \alpha t)$, where α is the coefficient of volumetric expansion of the gas for a unit degree of temperature = 0.00367 where t is the temperature expressed on the centigrade scale.

B. *Hypsometric Conditions.*—The pressure of the atmosphere at any place depends primarily on the weight of the superincumbent mass of air, and therefore diminishes as we ascend to greater heights. If the air is in motion, that and other considerations come in to affect the pressure; but if the air is quite relative to the earth's surface, then the pressure at any altitude is expressed by the so-called barometric or hypsometric formula

$$p = \int_{h_0}^h -\sigma g dh \quad \dots \quad (2)$$

where σ is the density and g the gravity for each layer of air whose vertical thickness is dh . The integral of this formula depends upon the vertical distribution of temperature, and moisture, and gravity; but under the simplest possible assumptions as to these vertical gradients, the following formula was deduced by Laplace and is generally known as his hypsometric formula:

$$h - h_0 = 18400 (1 + 0.00367t) \left(1 + 0.378 \frac{e}{p}\right) (1 + 0.0026 \cos 2\phi) \left(1 + \frac{h+h_0}{6370191}\right) (1 + 0.00157) \log \frac{p_0}{p} \quad 2a.$$

The modifications which this formula needs in order to adapt it to other hypotheses representing more nearly the actual distribution of temperature, moisture, and gravity, have been elaborately investigated by Angot in a memoir published in 1899 in Part I. of the *Memoirs of the Central Meteorological Bureau of France* for the year 1896. Angot, Hergesell, and Rykatcheff have also shown that for hypsometric work of any pretensions to accuracy it is simplest and best to use Laplace's formula for successive thin strata of air, and add together the individual results, rather than attempt a more complex single formula for the whole stratum; yet the latter seems to be essential for work in aerodynamics. In this formula t is the average temperature, e the average vapour tension of the layer of air, p the barometric pressure at the top of the layer, p_0 the pressure at the bottom, ϕ the latitude of the station, h the elevation above sea-level of the lower limit of the stratum, and h_0 that of the upper limit.

C. *Thermodynamic Relations.*—The temperature of the air is due to the quantity of molecular energy that is present in the form of heat, but usually there is also present a quantity of molecular energy that is spoken of as latent heat. This latent heat is said to do internal work, such as melting ice or boiling water, while the sensible heat does external work, such as expanding and pushing in all directions. These molecular energies can be transformed into each other over and over again without being sensibly diminished, and this power of transformation is expressed in the various equations of thermodynamics, of which the fundamental one for our purpose is

$$dQ = C_p dt + \Delta p dv = C_p dt + \Delta RT dv/v \quad \dots \quad (3)$$

This equation expresses the fact that when a quantity of heat measured in calories, dQ , is added to or taken from a volume of dry air, there may result both the change of temperature, dt , corresponding to one portion of the heat, $C_p dt$, and a quantity of external work corresponding to the remaining portion of the heat ($\Delta p dv$). It usually happens that the quantity of heat in a given mass of air does not remain the same for any length of time; it is diminished by radiation or is increased by absorption, and a certain quantity is lost when rain, snow, or hail drops down from the air, while a quantity is added to the atmosphere when moisture evaporates and mixes with the dry air as invisible vapour. The changes due to increase and diminution of moisture are usually small as compared with the great gain due to absorption and convection of solar heat, and with the loss by radiation. If these losses and gains are to be taken account of, then the quantity dQ in the above equation is finite and important. On the other hand, in some cases atmospheric processes go on so rapidly or in such peculiar circumstances—for instance, in the interior of a cloud—that the change in the quantity of heat may be considered as temporarily negligible. In these cases dQ is zero; the changes in temperature balance the changes in external work, and the thermal process is said to be adiabatic.

D. *The Condition of Continuity.*—When a mass of liquid or gas goes through several motions and changes without being disrupted or otherwise broken into smaller portions, and without the formation of bubbles or vacuous spaces in its interior, and when all the

changes that go on proceed by gradual continuous processes as to time, the mass of the fluid is subject to the law of continuity as to mass, and the motion of the fluid is continuous as to velocity. The latter condition is implied in the process of integration; the former is expressed by the equation of continuity

$$\frac{\partial \rho}{\partial t} + \frac{\partial(\rho u)}{\partial x} + \frac{\partial(\rho v)}{\partial y} + \frac{\partial(\rho w)}{\partial z} = 0 \quad (4)$$

where ρ is the density, t is the time, and ∂ the ordinary symbol for partial differentiation.

E. Conditions as to Energy and Motion.—When the total quantity of heat, both latent and sensible, remains constant or changes in a continuous manner, and when the motions are continuous, the mechanical and thermal processes are expressible by ordinary differentials and integrals. Motions of fluids involve both energy and inertia, and are subject to conditions expressed by the following equations of hydrodynamics:—

(a) Equations of energy. Let the kinetic energy be T , the potential energy V , the intrinsic energy W ; l, m, n , be cosines of the angle between the pressure p and the inwardly direct d normal to the boundary surface S . Then will

$$\frac{\partial(T+V+W)}{\partial t} = \iint p(lu+mv+nw)dS \quad (5)$$

(b) Equations of acceleration and inertia. Let P be the potential of the external forces acting on a unit mass of the atmosphere; μ , be the coefficient of viscosity or internal friction. Then will

$$\left\{ \begin{aligned} -\frac{\partial P}{\partial x} - \frac{1}{\rho} \frac{\partial p}{\partial x} &= \frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} + w \frac{\partial u}{\partial z} \\ &\quad - \mu \left[\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} \right] \\ -\frac{\partial P}{\partial y} - \frac{1}{\rho} \frac{\partial p}{\partial y} &= \frac{\partial v}{\partial t} + u \frac{\partial v}{\partial x} + v \frac{\partial v}{\partial y} + w \frac{\partial v}{\partial z} \\ &\quad - \mu \left[\frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} + \frac{\partial^2 v}{\partial z^2} \right] \\ -\frac{\partial P}{\partial z} - \frac{1}{\rho} \frac{\partial p}{\partial z} &= \frac{\partial w}{\partial t} + u \frac{\partial w}{\partial x} + v \frac{\partial w}{\partial y} + w \frac{\partial w}{\partial z} \\ &\quad - \mu \left[\frac{\partial^2 w}{\partial x^2} + \frac{\partial^2 w}{\partial y^2} + \frac{\partial^2 w}{\partial z^2} \right] \end{aligned} \right. \quad (6)$$

Approximate Assumptions and Solutions.—After introducing into the preceding system of fundamental equations (1-6) the actual conditions as accurately as they are known relative to gravity, solar radiation, the rotation of the earth, the viscosity of the air, its mass or inertia, its absorption and radiation of heat, its variable content of moisture, the precipitation of rain and cloud, the mutual interconversions of latent and sensible heat, a special difficulty occurs when we attempt to integrate these equations, because we have still to express analytically the initial conditions of the atmosphere as to pressure and temperature, and its boundary conditions as between the rough earth surface on the one hand and the unknown outward surface on the other. As the true earth's surface cannot possibly be represented by any algebraic formula, it is customary to assume simply that it is a uniform sphere, usually neglecting at least partially, if not wholly, the spheroidal shape. We next assume that there is no friction between the earth and the air. Thirdly, we assume that the power of the earth's surface to heat the air and to throw moisture by evaporation into the atmosphere is perfectly uniform. Finally, in many cases we go so far as to assume that the atmosphere is an incompressible rare liquid having a uniform density and a uniform depth of about 8000 metres, corresponding to the average standard density of dry air under a pressure of 760 millimetres and a temperature of 0° C. Even under these simplifications the analytic difficulties have been too great to admit of rigorous solutions, except in a few of the simplest cases. The treatment of atmospheric problems by Ferrel was followed by equally ingenious mathematical treatment by Professors Guldberg and Mohn, of Christiania, in two papers published by them in 1876 and 1880 respectively. These authors, like Ferrel, treat isolated portions of the atmosphere and obtain special solutions, which, however, have not the generality that must eventually be demanded in a rigorous and general discussion of the atmosphere as a whole. A more elegant mathematical solution of the subject was first given in 1882 by Oberbeck, of the University of Halle, in the *Annal. Phys.* xvii. p. 128. But even Oberbeck's solutions are obtained under various simplifying assumptions that restrict their satisfactory application to the daily weather maps. Oberbeck's first memoir treats of the mechanics of stationary cyclonic movements. Assuming that the isobars are concentric circles, and that in the outer portion of a cyclone the air has only horizontal movements, while in the inner portion it has only vertical movements, he solves his system of equations for the inner and outer

regions of the cyclone separately. He shows that in general the pressure increases on all sides outwards from the centre; the gradient also increases from the centre outwards to the limit of the inner region, whence it diminishes in the outer region and at a great distance becomes inappreciable. In both regions the paths of the wind are curved lines, logarithmic spirals, which cut the isobars or the radial gradient everywhere at the same angle; therefore, the movement of the air can be considered as a spiral inflow from all sides towards the centre. But the angle between the wind and the gradient follows different laws in the outer and inner regions, depending in the former on the rotation of the earth and the friction, but in the latter also on the intensity of the ascending current of air. In passing from the outer to the inner surface the wind experiences a sudden change of angle, so that the directions of the winds are not continuous, although the movement and the barometric pressures are assumed to be continuous. This latter peculiarity does not occur in nature, and is undoubtedly an analytical result peculiar to Oberbeck's method of treating the fundamental equations.

An improvement in the mathematical analysis was introduced by Dr F. Pockels of Göttingen in a memoir published in the *Met. Zeit.* for 1893, pp. 9-19. He deduces equations showing continuous changes of temperature, pressure, gradient, wind direction, and velocity from the centre of the cyclone to the outer edge of the anti-cyclone, or, more properly, the peri-cyclone; these, therefore, may reasonably be supposed to have their counterparts in nature. Such mathematical solutions, however, are based upon the assumption that we are dealing with a comparatively small portion of the earth's surface, which may be considered as a plane and as having a uniform diurnal rotation and a uniform coefficient of friction. Moreover, the cyclones and anti-cyclones are assumed to be stationary and permanent by reason of the perfect balance of all the forces involved therein. Of course these conditions are not exactly fulfilled, but in general Pockels shows that his theoretical results agree fairly well with the observed conditions as to wind and pressure. He computes the actual distribution of these elements under the assumption that the centre of the anti-cyclone is at latitude 55.5, and that the coefficient of friction is 0.00008.

Notwithstanding the fact that these difficult mathematical investigations still lead us to unsatisfactory results, they are yet eminently instructive as showing the methods of interaction of the various forces involved in the motions of the atmosphere. We must, therefore, mention the interesting attack made by Oberbeck upon the problem of the general circulation of the atmosphere. His memoir on this subject was published in the *Sitzungsberichte* of the Academy of Sciences at Berlin in 1888. The fundamental assumption in this memoir implies that there is a general and simple system of circulation between the equatorial and the polar regions, but the eventual solution of the problem leads Oberbeck to two independent systems of winds, an upper and a lower, without any well-defined connexion at the polar and equatorial ends of these two currents, so that after all they are not rigorously re-entrant. Among the hypotheses introduced in the course of his mathematical work, the most important, and perhaps the one most open to objection, is that the distribution of temperature throughout the atmosphere in both the upper and lower strata can be represented by the equation $T=A+B(1-3\cos^2\theta)$. Undoubtedly this equation represents observations in the lower strata near the surface of the earth, but the constants that enter into it, if not the form itself, must be changed for the upper strata. The solution arrived at by Oberbeck gives the following equations representing the movement of the components of the movement of the atmosphere towards the vertical V , towards the north N , and towards the east O :—

$$\begin{aligned} V &= C(1-3\cos^2\theta)f \\ N &= -6C\cos\theta\sin\theta\phi \\ O &= D[\sin\theta(1-3\cos^2\theta)g+6\cos^2\theta\gamma]. \end{aligned}$$

In accordance with these equations he deduces the general circulation of the atmosphere as follows:—In the lower current the air flows from the polar regions towards the south-east and north-east until it reaches the parallel of 30° or 40°; it then turns directly towards the equator, and eventually towards the south-west and north-west, until at the equator it becomes a strong easterly wind (or a so-called westerly current). In the upper layer the movement begins as an easterly wind, turns rapidly to the north at latitude 20° or 30°, and then becomes a south-westerly wind (or north-eastern current) in the northern hemisphere, but a north-westerly wind and south-eastern current in the southern hemisphere. Of course in the highest strata of air the currents must diminish in strength. In a second paper in the same year, 1888, Oberbeck determines the distribution of pressure over the earth's surface as far as it is consistent with his system of temperatures and winds. His general equation shows that as we depart from the equator the pressure must depend upon the square and the fourth power of the cosine of the polar distance or the sine of the latitude, and in this respect harmonizes with Ferrel's work of 1859, although more

general in its bearings. By comparing his formulæ with the observed mean pressure in different latitudes, Oberbeck obtains the general angular velocity of the air relative to the earth, *i.e.*, $0.0292 \left\{ \sin^2 \phi - 0.0836 \right\}$, which is quite small and is a maximum (4.6 metres per second) at latitude S. $56^\circ 27'$.

Contemporary with Oberbeck's are the admirable memoirs by Professor Dr Diro Kitao of the University of Tôkyô, who, as a student of mathematics in Germany, had become an expert in the modern treatment of hydrodynamic problems. In three memoirs published by the Agricultural College of the University of Tôkyô in the German language in the years 1887, 1889, and 1895, he develops with great patience many of the minutiae of the movement of the earth's atmosphere and cyclonic storms. The assumptions under which he conducts his investigations do not depart from nature quite so far as those adopted by other mathematicians. Like Ferrel, he adheres as closely as possible to the results of physical and meteorological observations; and although, like all pure mathematicians, he considers Ferrel as having departed too far from rigorous mathematical methods, yet he also unites with them in acknowledging that the results attained by Ferrel harmonize with the meteorology of the earth. The fact is that the solution of the hydrodynamic equations is not single, but multiplex. Every system of initial and boundary conditions must give a solution appropriate and peculiar to itself. The actual atmosphere presents us with the solution or solutions peculiar to the conditions that prevail on the earth. Entirely different conditions prevail on Jupiter and Saturn, Venus and Mars, and therefore a wholly new series of problems pertain to the various planets of the solar system. It matters not whether we attempt to resolve our equations by introducing terrestrial conditions expressed by means of analytical algebraic formulæ, and integrate the equations that result, or whether we adopt a graphic process for the representation of observed atmospheric conditions and integrate by arithmetical, geometrical, or mechanical processes. In all cases we must come to the same result, namely, our resulting expressions for the distribution of pressure and wind will agree with observations just as closely as our original equations represented the actual temperatures, resistances, and other attending conditions. In the last portion of Kitao's third memoir he gives some attention to the interaction of two cyclonic systems upon each other when they are not too far apart in the atmosphere, and shows how the influence of one system can be expressed by the addition of a certain linear function to the equations representing the motions of the other. He even gives the basis for the further study of the extension of cyclonic storms into higher latitudes where conditions are so different from those within the tropics. Finally, he suggests in general terms how the resistances of the earth's surface, in connexion with the internal friction or viscosity of the air, are to be taken into consideration, and shows under what conditions the assumptions that underlie his own solutions may, and in fact must, very closely represent the actual atmosphere.

The General Theory of the Circulation of the Atmosphere.—If the meteorologist had a sufficient number of observations of the motions of the winds and clouds to represent both the upper and lower currents, he would long since have been able to present a satisfactory scheme showing the average movement of the atmosphere at every point of its course, and the paths of the particles of air as they flow from the poles to the equator and return. This motion has been called the general circulation of the atmosphere; it would be a complex matter even if the surface of the earth were homogeneous and without special elevations, but the actual problem is far different. Something like this general circulation is ordinarily said to be shown by the monthly and annual charts of pressure, winds, and temperature, such as were first prepared and published by Buchan in 1868, and in Bartholomew's *Physical Atlas* of 1899. We must not, however, imagine that such charts of averages can possibly give us the true path of any small unit mass of air. The real path is a complex curve, not re-entrant, which is never described twice over, and would not be even if we had an ideal atmosphere and globe. It is a compound of vertical and undulatory movements in three dimensions of space, variable as to time, which cannot properly be combined into one average. The average temperatures, winds, and pressures presented on these charts suggest hypothetical problems to the student's mind quite different from the real problems in the mechanics of the atmosphere—problems that may, in fact, be impossible of solution, whereas those of the actual atmosphere are certainly solvable. The momentary condition presented on any chart of simultaneous observations belongs to the real, natural, and important questions of meteorology. The efforts of mathematicians and physicists have been devoted to these ideal conditions because of their apparent simplicity, whereas the practical problems offered by the daily weather chart are now so easily accessible that attention must be turned towards them. The most extensive system of homogeneous observations appropriate to the study of the dynamics of the atmosphere is that shown in the *Daily Bulletin of International Simultaneous Observations*, published by the U.S. Signal Service in

the years 1875–84, with monthly and annual summaries, and a general summary in "Bulletin A," published by the U.S. Weather Bureau in 1893. The study of these daily charts for ten years shows how the general circulation of the atmosphere differs from the simple problems presented in the idealized solutions based on monthly and annual averages. The presence of a great and a small continent, and a great and small ocean, and especially of the moisture, with its consequent cloud and rain, has complicated and altered the problem. Nevertheless, it is important for us to follow the historical development of our subject. The most prominent features of the general circulation of the atmosphere are the system of trade winds, north-easterly in the northern tropics, and south-easterly in the southern tropics, the system of westerly winds beyond the trade-wind region, namely, north-westerly in the north temperate and south-westerly in the south temperate zone, and again the system of upper winds shown by the higher clouds, namely, south-westerly in the northern hemisphere and north-westerly in the southern.

Halley in 1680, and Hadley in 1735, gave erroneous or imperfect explanations of the mechanical principles that bring about these winds. As some errors in regard to this subject are still current, it is necessary to say that it is erroneous to teach that atmospheric air weighs less on being heated, or by reason of the infusion of more moisture, and that therefore the barometer falls. The addition of more moisture must increase its weight as a whole; heat, being imponderable, cannot directly affect its weight either way. We are liable to disseminate error by the careless use of the word "lighter," since it means both a diminution in absolute weight and a diminution in relative weight or specific gravity. Heat and moisture may diminish the specific gravity of a given mass of air by increasing its volume, or of a given volume by diminishing its mass, but neither of them can of themselves affect the pressure shown by the barometer so far as that is due to the weight of the atmosphere. It is not proper to say that by warming the air, thereby diminishing its specific gravity and causing it to rise, so that colder air flows in to take its place, we thereby diminish the barometric pressure. It is easily seen that in the expression $p = RT/v$, which, as we have before said, is the law of elasticity, T and v may so vary as to counterbalance each other, and allow the pressure p to remain the same. Within any given room or other enclosure, as between the equator and the pole, hot air may rise on one side, flow over to the opposite, cool and return, and the circulation be kept up indefinitely without any necessary change in pressure. The problem of the relation between wind and pressure is more complex than this, and involves the consideration of the inertia of the masses of air that are in motion with the earth around its axis. The air is so extremely mobile that it moves quickly in response to slight differences in pressure that cannot be detected by ordinary barometric measurement. The gradients or differences of pressure that are shown on meteorological charts, whether daily, or monthly, or annual, are not directly, but only very indirectly, due to buoyancy, as caused by heat and moisture. The pressure gradients so-called are not merely the prime causes of the winds, but are equally and essentially the results of the winds. They are directly due to the fact that the atmosphere is rapidly revolving with the surface of the earth around the earth's axis, while at the same time it may be circulating about a storm centre. Inappreciable differences of pressure start the winds in motion, and the air moves towards the region of low pressure, just as in the pneumatic despatch tubes the flow of air towards the low pressure carries the packages along. But in the free air, where there are no important resistances to be overcome, the freedom of motion is greater than in these pneumatic tubes. No sooner is the atmosphere thus set in motion from all sides towards the central low pressure than it rapidly acquires a spiral circulation, and thereby, in addition to the slight diminution of pressure in the direction of the motion of the wind, there is superimposed a much more decided one towards the left hand from the wind, and an equally rapid increase towards the right hand. This gradient of pressure, perpendicular to the direction of the wind, is far greater than that in the direction of the wind, and is that which produces the areas of decided low and high pressures that appear as storm centres and fair-weather centres respectively on the daily weather map. Therefore, in general, the wind cuts across the chartered isobars in directions oblique to these curved lines, and at angles which are nearly 90° for the feeble winds far removed from the centres, but which are almost zero for the most violent winds near the low centre. The winds acquire this spiral circulation for two reasons—(a) all straight line gusts or jets in fluids, subject to any form of resistance, necessarily break up into rotating spirals whenever the velocity exceeds a certain limit, because the resistances of the viscosity deprive some particles of the fluid of a little more of their original velocity and energy than the other particles near by them, and thus the whole series is drawn away from linear into curvilinear paths; (b) in addition to their rectilinear motions the particles of air have a rapid circular motion in common with the whole atmosphere diurnally around the earth's axis. Therefore every particle of moving air comes

under the influence of a set of forces depending on its own rate of motion, relative to the earth's surface and its position relative thereto. If the particles are moving eastwards, viz., in the same direction as the earth's diurnal rotation, then the result is as though the atmosphere were rotating more rapidly than does the earth at present; consequently the particles of wind push towards the equator as though the atmosphere were trying to adopt a more flattened spheroidal figure corresponding to its greater velocity of rotation. If the particles are moving westwards, on the other hand, it is as though the atmosphere were revolving less rapidly than the earth, and as though the flattened spheroid of revolution due to the present rate of rotation were more decidedly flattened than need be; consequently the particles of air push towards the poles. If the winds blow towards either pole, then their initial moment of inertia about the earth's axis, due to the initial radius and the eastward movement of the air, must be retained; consequently, as the air advances into higher latitudes and to smaller circles of diurnal rotation its velocity must increase, and must carry the particles to the east of their initial meridians. If the wind blow towards the equator its initial moment of inertia must be applied to a larger radius, and its velocity correspondingly diminished, so that it is left behind or falls away somewhat to the west. "The reasoning, therefore, of those who in attempting to explain the trade winds assume that the atmosphere in moving towards or from the equator has a tendency to retain the same original linear velocity is erroneous" (Ferrel's *Movements of Fluids*, 1859). In general the winds tend to retain their moments of inertia, and in the northern hemisphere must necessarily always be deflected continuously towards the right hand. The exact amount of this deflection was first distinctly stated by Poisson, as applied to the movements of projectiles; it was also announced by Tracy of New Haven in 1843, but was first applied to the atmosphere by Ferrel, who deduced its meteorological consequences. This law is not to be confounded with that of Buys Ballot, who in 1861 deduced from the weather charts of western Europe the rule that the gradient of pressure shown on the weather map for any day would be followed in twenty-four hours by a wind perpendicular to that gradient, and having the lower pressure on the left hand. Buys Ballot's law was in the nature of a rule for prediction, and was modified by Buchan, who enunciated the following: "The wind blows towards the regions of low pressure, but is inclined to the gradient at an angle which is less than 90°." In this form Buchan's law was an improvement upon the laws current among cyclonologists, who had assumed that, in a rough way, the wind blew in circles around the low centre, and was therefore sensibly at right angles to the gradient. It ought, however, to be said that Redfield throughout the whole course of his studies, from 1831 to 1857, never gave adherence to this view, and in fact determined the average inclination of the movements of the lower clouds at New York City to be about 7° inwards as compared with the truly circular theory, at least for the severer portions of hurricanes. Now Ferrel's law explains mechanically the reason why the winds do not blow exactly radially or circularly, and gives the means for determining their inclination to the isobar in all portions of the cyclone, and for various degrees of resistance by the earth's surface. The general proposition that the barometric gradients on the weather map are not those that cause the wind, but are, properly speaking, the result of the combined action of the wind, the rotation of the earth, and the friction of the earth's surface, as first explained by Ferrel, seems to have been neglected by meteorologists until brought to their attention repeatedly by the present writer between 1869 and 1875. In 1874 Professor Hann published a review of Ferrel's work that rectified this important oversight. The independent investigations of Sprung, Koepfen, Finger, and especially Guldberg and Mohn, confirm in general the correctness of Ferrel's views.

It is quite erroneous to imagine that the low pressures in storm regions and in the polar regions, and especially the belt of low pressure at the equator, are due simply to the diminution of the density and weight of the air by the action of its warmth or its moisture, or to the abundant rainfall as relieving the atmosphere of the weight of water. It has been clearly shown that none of these operations can directly affect the barometric pressure to any appreciable extent, but that high and low pressure areas, as we see them on the weather map, owe their existence entirely to the mechanical interaction of the diurnal rotation of the earth and the motions of the atmosphere. Both Espy and Hann have abundantly shown that the formation and downfall of rain do not produce any low barometric pressure unless they produce a whirling action of the wind—that, in fact, the latent heat evolved by the condensation of vapour into rain may so warm up the cloud as to produce a temporary rise in pressure even at the surface of the ground, due to the downward push produced by the sudden expansion of the cloud, analogous to the backward kick of a gun when shot off. The force with which the wind presses to the right or tends to be deflected in that direction is $2n \sin \phi$, while the curvature of the path of the wind is measured by its radius of curvature, which is $v/2n \sin \phi$, where v is the velocity of the wind, n is the equatorial

velocity of the earth's rotation, and ϕ is the latitude. It will be seen from this that there is no deflection at the equator; therefore, as Ferrel stated, there is no tendency to the formation of great whirlwinds at the equator, hence hurricanes and typhoons are rarely found within 10° of the equator.

Ferrel frequently speaks of an anti-cyclone, whereby he means the area of high pressure just outside of a strong cyclonic whirl; the expression peri-cyclone would have been more appropriate and is sometimes substituted. The term *anti-cyclone*, as first introduced by Galton in 1863, is applied to a system of winds blowing out from a central area of high pressure, and this is the common usage of the term in modern meteorology. The term cyclone among meteorologists and throughout English literature, except only a few cases in the United States, is equivalent to the older usage of whirlwind, and it is unfortunate that misunderstandings often arise because local usages in America apply the word cyclone to what has for centuries been called a tornado. The mechanical principles discussed by Ferrel led him to an algebraic relation between the barometric gradient G , the wind velocity v , the radius of curvature of the isobar r , and the inclination i between the wind and the isobar, which is expressed by the following formula for the pressures that prevail at sea-level:—

$$G = [(2n \sin \phi + \cos i v/r) v \sec i] / [83,000,000].$$

A popular exposition of this and other results of Ferrel's work is given by Archibald in *Nature*, 4th May 1882, and still better in Ferrel's *Treatise on the Winds*, New York, 1897.

The charts of mean annual pressure, temperature, and winds above referred to show certain broad features that embrace the whole system of atmospheric circulation, viz., the low pressures at the equator and the poles, the high pressures under the tropics, the trade winds below and the anti-trades above, with comparative calms under the belts of equatorial low pressure and tropical high pressure. The first effort of the mathematician was to explain how these mean average conditions depend upon each other, and to devise a system of general circulation of the wind consistent with the pressures, resistances, and densities. But, as we have already said, such a system may be very far from that presented by the real atmosphere, and little by little we are being led to a different view of the question of the general circulation. The earlier students of storms generally accepted one of two views as to the cause of whirlwinds. They were either—(1) formed mechanically between two principal currents of air flowing past each other, the so-called polar and equatorial currents; or (2) they were due to the ascent of buoyant air while the heavier air flowed in beneath, the whirling motion being communicated by the influence of the rotation of the earth, or by the greater resistances on the one side or the other. In order to explain why hurricanes and typhoons exist continuously for many days, or even weeks, it is necessary that there should be a source of energy which would maintain a continued buoyancy and rising current at the centre, and this was supposed to be fully provided for by Espy's proof of the liberation of latent heat consequent on the formation of cloud and rain. To this latter consideration the present writer has added the even more important influence of the sun's heat intercepted at the upper surface of the cloud. At this stage of the investigation the whirlwind was but an incident in the general circulation of the atmosphere, but further consideration showed that it ought rather to be regarded as an essential portion of that circulation, and that when temperature gradients and density gradients exceeded a certain limit the formation of great whirlwinds was inevitable. Therefore, an atmosphere containing several whirlwinds is just as truly a system of general circulation in the one case as an atmosphere without a whirlwind is in the other. The formation of rain, the evolution of latent heat, and even the absorption of heat at the upper surface of the cloud really constitute a normal general circulation in this special case.

In 1890 Professor Hann published a careful analysis of the actual temperature conditions prevailing over an extensive area of high pressure in Europe, and showed that the temperatures of the upper strata in both high and low areas, namely, in anti-cyclones and cyclones, are often directly contrary to those supposed to prevail by Espy and Ferrel. This study necessitated a more careful examination into the radiation of heat from the dust and moisture of the atmosphere, and the present writer seems to have shown that in areas of high pressure and clear weather a very slow descending movement throughout each horizontal layer gives time for the radiation of heat that will fully explain the anomalies of temperature. On the other hand, von Helmholtz in several memoirs of 1888–91 showed that waves or billows may be formed in the atmosphere of great extent at the dividing surface between upper and lower strata moving in different directions and with different velocities. Under specific conditions these billows may become like the breakers and caps of waves of the ocean when driven by the wind. The hypothesis that these aerial breakers correspond to our storms and troughs of low pressure experienced in the lower atmosphere is very plausible. As these billows are

formed between upper and lower air currents of great extent, which themselves represent a large portion of the horizontal circulation between the poles and the equator, it results that if von Helmholtz's suggestion and Hann's hypothesis are correct then our storms must be considered as essentially incidents in the general circulation rather than as caused by the vertical circulation over any locality. It must occur to every one to adopt the intermediate view that, on the one hand, the local vertical circulation, with its clouds, rain, hail, and snow, and evolution of latent heat, and, on the other, the waves and whirls in the general circulation, mutually contribute toward our storms and fair weather. It only remains to allot to each its proper importance in any special case.

Undoubtedly aerial billows, and the clouds that must frequently accompany them, exist everywhere in the earth's atmosphere. Perhaps their extent and importance are not properly appreciated. A voyage around the Atlantic Ocean in 1889-90, made by the writer, specifically to study cloud phenomena, revealed many remarkable cases, such as the cumulus rolls that extend in a remarkably symmetrical series from the island of Ascension westwards for a hundred miles in the south-easterly trades, or the delicate fields of cirro-cumuli that extend from the islands of Santa Lucia and Barbados for two hundred miles eastwards under favourable conditions. The mixtures and vorticoose motions going on within aerial billows to form these clouds have been interpreted by Brillouin; but to a certain extent we must still agree with Ferrel, who could not accept the conclusion that the great storms, in which ascending currents and heavy rains are the most prominent features, depend to any extent on these phenomena of mixture, and therefore on the general circulation of the atmosphere.

Mathematicians have, almost without exception, assumed a so-called steady condition in the motion of the atmosphere in order to achieve a successful integration of the general equations of motion. The restrictions within which Helmholtz and others have worked, and the limits within which their results are to be accepted, have been analysed by Dr E. Herrmann in a memoir of which a translation is published in the bulletin of the American Mathematical Society for June 1896. Of course Herrmann's own investigation is also based upon certain simplifying hypotheses, such as the absence of outside disturbing forces and of viscosity and friction, a homogeneous ellipsoidal surface, and a uniform initial temperature and rate of revolution corresponding to an initial state of equilibrium. If now the initial static equilibrium be disturbed by introducing a different distribution of temperature, viz., one that varies with altitude and latitude, but is uniform in longitude along any circle of latitude, then the first question is whether the atmosphere can settle down to a new state of static equilibrium. Herrmann shows that in general it cannot do so, but that the new state and the future states can only be one of motion and dynamic equilibrium. If, however, there be no external forces acting on the atmosphere, then in one case static equilibrium relative to the earth can occur, namely, when the new temperatures are so distributed in the atmosphere as to satisfy the equation

$$\int \rho r^2 \omega dV = M,$$

in addition to the ordinary equations of elasticity, inertia, and continuity previously given, and to those representing the boundary conditions, M being the total amount of inertia of the atmosphere relative to the axis of rotation. In general, the movements in the atmosphere must consist not only of an interchange between the poles and the equator, but also of east and west motions, and there must therefore be a different rate of diurnal rotation for each stratum. The second step in this inquiry is, Can these movements become perfectly steady with this unvarying or steady distribution of temperature? In other words, Can the temperature and the movements be so adjusted to each other that each shall remain invariable within any given zone of latitude? The reply to this is, that the temperatures and the movements, if they are to become thus adjusted, must satisfy a certain differential equation which itself shows that steady motions and stationary temperatures cannot exist if there is any north or south component. Apart from the fact that Herrmann assumes no friction, it would seem that he has proved that steady motions and stationary pressures cannot exist in the atmosphere over a homogeneous globe, and presumably the same result would follow for the irregular surface of the actual globe. The motions of the real atmosphere must therefore consist of irregularities and periodic oscillations superimposed upon more uniform, regular progressions, but never repeating themselves. Consequently, the conclusions deduced by those who have assumed that stationary conditions are possible must depart more or less from meteorological observations. There is a general impression that the belt of low pressure at the equator and the low areas at the poles and the high pressures under the tropics are pseudo-stationary, and really represent what would be steady conditions if we had an ideal smooth globe; but Herrmann's researches show that the unsteady-

ness observed to attach to these areas under existing conditions would also attach to them under ideal conditions. They really have and must have irregular motions, and we, by taking annual averages, obtain an ideal annual distribution of pressure, temperature, and wind that does not represent any specific dynamic problem. The averages represent what is considered proper in climatology, but are quite improper and misleading from a dynamic point of view, and have no simple logical connexion with each other.

Closely connected with this study of steady motions under a constant supply and steady distribution of solar heat comes the further question as to whether regular seasonal variations in atmospheric pressure and wind can be produced by regular seasonal variations in the heat received from the sun; for instance, a variation in the earth's atmosphere corresponding to the periodic variations of the solar spots. The general current of Helmholtz's investigations seems to show that no periodic change in the earth's atmosphere can be maintained for any length of time by a given periodic influence outside of the atmosphere. On the other hand, it is barely possible that wave and vortex phenomena on the sun's surface may have the same periodicities as regular phenomena in the earth's atmosphere, so that there may be a parallelism without any direct connexion between the two.

An important paper on the application of hydrodynamics to the atmosphere is that by Professor V. Bjerknes, of Stockholm, Sweden, which was read in September 1899 at Munich, and is now published in English translation by the U. S. Weather Bureau. In this memoir Bjerknes applies certain fundamental theorems in fluid motion by Helmholtz, Kelvin, and Silberstein, and others of his own discovery to the atmospheric circulation. He simplifies the hydrodynamic conceptions by dealing with density directly instead of temperature and pressure, and uses charts of "isosteres," or lines of equal density, very much as was proposed by the present writer in 1889 in his *Preparatory Studies*, where he utilized lines of equal buoyancy or "isostaths." Bjerknes has thus made it practicable to apply hydrodynamic principles in a simple manner without the necessity of integrating the equations, at least for many ordinary cases. He also gives a criterion by which we may judge between the physical theory of Espy and Ferrel, according to which cyclones are perpetually renewed, and the mechanical theory according to which the cyclone is simply carried along in the general atmospheric current. Bjerknes's paper is illustrated by another one due to Mr Sandström, of Stockholm, who has applied these methods to a storm of September 1898 in the United States. The further development of Bjerknes's methods promises a decided advance in theoretical and practical meteorology. They are also applicable to the problems of oceanic circulation.

The Diurnal and Semi-diurnal Periodicities in Barometric Pressure.—For a long time attempts were made to explain the periodic variations of the barometer by a consideration of static conditions, but it is now evident that this problem, like that of the circulation of the atmosphere, is a question of aerodynamics. A most extensive series of researches into the character of the phenomena from an observational point of view has been made by Dr Julius Hann, who has also given a summary of the present condition of our knowledge of the subject in the *Met. Zeit.* for 1898, which has been translated by Mr R. H. Scott in the *Quarterly Journal of the Royal Meteorological Society* for January 1899 (see also an important addition by Hann and Trabert in the *Met. Zeit.* for November 1899). Professor Hann has shown that at the earth's surface three regular periodic variations are established by observation, viz., the diurnal, semi-diurnal, and ter-diurnal. On the higher mountains these variations change their character with altitude. (1) At the equator the diurnal variation is represented by the formula $0.30 \text{ mm.} \sin(5^\circ + x)$, where x is the local hour angle of the sun. In higher latitudes either north or south the coefficient $A_1 = 0.30 \text{ mm.}$ diminishes, but the phase angle, 5° , varies greatly, generally growing larger. It is therefore evident that this diurnal oscillation depends directly on the hour angle of the sun, and probably, therefore, principally on the amount of heat and vapour received by the atmosphere from the ocean and the ground at any locality and season of the year. It is apparently but little affected by the wind, but somewhat by altitude above sea; the amplitude diminishes to zero at a certain elevation, and then reappears and increases with the opposite sign; the phase angle does not change. (2) Superimposed upon this diurnal oscillation is a larger semi-diurnal one, which goes through its maximum and minimum phases twice in the course of a civil day. The amplitude of this variation is largest in equatorial regions, and is expressed by the formula $A_2 = (0.988 \text{ mm.} - 0.573 \text{ mm.} \sin^2 \phi) \cos^2 \phi$ as given by Hann, or $A_2 = (0.92 \text{ mm.} - 0.495 \sin^2 \phi) \cos^2 \phi$ as revised by Trabert. This amplitude also may be considered as variable along each zone of latitude having a maximum value on certain central local meridians. The times at which the semi-diurnal phases of maximum and minimum occur are subject to laws different from those for the diurnal period. Within the tropics the phase angle is 160°

and at 50° N. it is 147°, and between these limits it seems to be the same over the whole globe, so that the phase does not depend clearly upon the hour angle of the sun or on the local time. The amplitudes appear to depend on the excess of land in the northern hemisphere as compared with the water and cloud of the southern hemisphere. The amplitude also varies during the year, being greatest at perihelion and least at aphelion. Hann suggests that this is an indirect effect of the sun's heat on the earth, as the northern hemisphere is hotter when the earth is in aphelion than is the southern hemisphere when the earth is in perihelion, owing to the preponderance of land in the north and water in the south.

(3) The ter-diurnal oscillation has the approximate value shown by the formula $0.04 \text{ mm. sin } (355^\circ + 3x)$. The phase angle is sensibly the same everywhere, and the amplitude varies slightly with the latitude. Both phase and amplitude have a pronounced annual period which is as remarkable as that of the semi-diurnal oscillation; the maximum amplitude occurs in January in the northern hemisphere, and in July in the southern.

The dynamics and physics of the atmosphere have not yet been explored so exhaustively as to explain fully these three systematic barometric variations, but neither have we as yet any necessity for appealing to some unknown cosmic action as a possible cause of their existence. The action of the solar heat upon the illuminated hemisphere, and the many consequences that result therefrom, may be expected to explain the barometric periods. The variations of sunshine and cloud must inevitably produce periodic variations of temperature, moisture, pressure, and motion, whose exact laws we have not as yet fathomed. Among the many methods of action that have been studied or suggested in connexion with the barometric variations the most important of all is the so-called tidal wave of pressure due to temperature. Laplace applied his investigations on the tides to the gravitational tide of the ocean, and when he passed to the corresponding solar and lunar gravitational tides of the atmosphere he was able to show that they must be inappreciable, unless, indeed, certain remarkable relations existed between the circumference of the earth and the depth of the atmosphere. As these relations do not exist, it is generally conceded as certain that the gravitational tides, both diurnal and semi-diurnal, cannot exceed a few thousandths of an inch of barometric pressure. On the other hand, the same process of mathematical reasoning enables us to investigate the action of the sun's heat in producing a wave of pressure that has been called a pressural tide, due to the expansion of the lower layer of air on the illuminated half of the globe. The laws that must govern these pressural tides have been investigated by Kelvin, Rayleigh (*Phil. Mag.* February 1890), and especially by Margules (*Vienna Sitz. Ber.* 1890-93). The two latter have shown the truth of a proposition enunciated by Kelvin in 1882, without demonstration, to the effect that the free oscillation produced by a relatively small amount of tide-producing force will have an amplitude that is larger for the half-day term than for the whole-day term. They therefore explain the diurnal and semi-diurnal variations of the barometric pressure as simple pressural tides or waves of expansion, originally produced by solar heat, but magnified by the relation between forced and free waves in an atmosphere on a globe having the specific dimensions of our own. The analytical processes by which Laplace and Kelvin arrived at this special solution of the tidal equation were objected to by Airy and Ferrel, but the matter has been, as we think, most fully cleared up by Dr G. H. Ling, in a memoir published in the *Annals of Mathematics* in 1896. He seems to have shown that, although a literally correct result was attained by Laplace, his methods were at fault from a rigorous and analytical point of view, at least in so far as they are presented in the *Mécanique Céleste*. The process by which a diurnal temperature wave produces a semi-diurnal pressure oscillation, as explained by Rayleigh and Margules, may be stated as follows: The diurnal temperature wave having a twenty-four hours period is the generating force of a diurnal pressure tide, which is essentially a forced and small oscillation. The natural period of the free waves in the atmosphere agrees much more nearly with twelve than with twenty-four hours. In so far as the forced and the free waves reinforce each other, the semi-diurnal waves are reinforced far more than the other, so that a very small semi-diurnal term in the temperature oscillations will produce a pressure oscillation two or three times as large as the same term would in the diurnal period. These reinforcements, however, depend upon the elastic pressure within the atmosphere, just as does the velocity of sound. If the prevailing barometric pressures were slightly increased, the adjustment of the twelve-hours free wave of pressure to the forced wave of temperature could be so perfect that the barometric wave would increase to an indefinite extent. For the actual temperatures the periodicity of the free wave is about thirteen hours, or somewhat longer than the forced wave of temperature, so that the barometric oscillation does not become excessive. It would seem that we have here a suggestion to the effect that if in past geological ages the average temperature at any time has been about 268° C. on the absolute scale, then the pressure waves could have been so large as to produce

remarkable and perhaps disastrous consequences, involving the loss of a portion of the atmosphere.

The Thermodynamics of a Moist Atmosphere.—The preceding section deals with an incompressible gas, and therefore with simple, pure hydrodynamics. If now we introduce the conception of an atmosphere of compressible gas, whose density increases with altitude, so that rising and falling currents change their temperatures by reason of the expansion and compression of the masses of air, we take the first step in the combination of thermodynamic and hydrodynamic conditions. If we next introduce moisture, and take precipitation into consideration, we pass to the difficult problems of cloud and rain that correspond more nearly to those which actually occur in meteorology. This combination has been elucidated by the works of Espy and Ferrel in America, Kelvin in England, Hann in Austria, but especially by Hertz, Helmholtz, and von Bezold in Germany, and by Brillouin in France. A most complete study of the subject will be found in Prof. Bigelow's report on the cloud work of the U.S. Weather Bureau.

The proper treatment of this subject began with the memoir of Kelvin on convective equilibrium (see *Trans. Manchester Phil. Soc.* 1861). The most convenient method of dealing approximately with the problems is graphic and numerical rather than analytical, and in this field the pioneer work was done by Hertz, who published his diagram for adiabatic changes in the atmosphere in the *Met. Zeit.* in 1884. He considers the adiabatic changes of a kilogram of mixed air and aqueous vapour, the proportional weights of each being λ and μ respectively. In a subsequent elaborate treatment of the same subject by von Bezold in four memoirs published during 1889 and 1899, the formulæ and methods are arranged so as to deal easily with the ordinary cases of nature which are not adiabatic; he therefore prepares diagrams and tables to illustrate the changes going on in a unit mass of dry air to which has been added a small quantity of aqueous vapour, which, of course, may vary to any extent. Both Hertz and von Bezold consider separately four stages or conditions of atmosphere:—(A) The dry stage, where aqueous vapour to a limited extent only is mixed with the dry air. (B) The rain stage, where both saturated vapour and liquid particles are simultaneously present. (C) The hail stage, where saturated aqueous vapour, and water, and ice are all three present. (D) The snow stage, where ice vapour and snow itself, or crystals of ice, are present. The expressions aqueous vapour and ice vapour do not occur in Hertz's article, but are now necessary, since Marvin, Fischer, and Juhlin have been able to show that vapour from water and vapour from ice exert different elastic pressures, and must therefore represent different modifications of liquid water. According to Hertz, we may easily follow this mass of moist air as it rises in the atmosphere, if by expansion it cools adiabatically so as to go successively through the four preceding stages. For a few thousand feet it remains dry air. It then becomes cloudy and enters the second stage. Next it rises higher until the cloudy particles begin to freeze into snow, sleet, or hail, which characterizes the third stage. When the hail has fallen and the remainder of the cloud has ascended higher, it contains only ice particles and the vapour of ice, a condition which characterizes the fourth or snow stage. If in this condition we give it plenty of time the precipitated ice or snow may settle down, and the cloudy air, becoming clear, return to the first stage; but the ordinary process in nature is a circulation by which both the cloud and the air descend together slowly, warming up as they descend, so that eventually the mixture returns to the first stage at some level lower than the clouds, though higher than the starting point.

The exact study of the ordinary non-adiabatic process must be carried out by the help of Prof. Bigelow's tables, but the approximate adiabatic study is so helpful that in Fig. 10 we have traced a few lines from Hertz's diagram sufficient to illustrate its use and convenience. The reader will perceive a horizontal line at the base representing sea-level; near the middle of this line is zero centigrade; as we ascend above this line into the upper regions of the air we come under lower pressures, which are shown by the figures on the left-hand side. The scale of pressures is logarithmic, so that the corresponding altitudes would be a scale of equal parts. The temperature and pressure at any height in the atmosphere are shown by this diagram. If the air is saturated at a given temperature, then the unit volume can contain only a definite number of grams of water, and this condition is represented by a set of moisture lines, indicated by short dashes, showing the temperature and pressure under which 5, 10, or 20 grams of water may be contained in the saturated air. Let us now suppose that we are following the behaviour of a kilogram mass of air rising from near sea-level, where it has a pressure of 750 millimetres, a temperature of 27° C., and a relative humidity of 50 per cent. A pointer pressing down upon the diagram at 750 millimetres and 27° C. will represent this initial condition. A line drawn through that point parallel to the moisture lines will show that if this air were saturated it could contain about 22 grams of water; but inasmuch as the relative humidity is only 50 per cent., therefore it

actually contains only 11 grams of water, and an auxiliary moisture line may be drawn for this amount. If now the mass rises and cools by expansion, the relation between pressure and temperature will be shown by the line $\alpha \alpha$. When this line intersects the inclined moisture line for 11 grams of water we know that the rising mass has cooled to saturation, and this occurs when the pressure is about 640 millimetres and the temperature 13.2°C . By further rise and expansion a steady condensation continues, but by reason of the latent heat evolved the rate of cooling is diminished and follows the line $\beta \beta$. The condensed vapour or cloud particles are here supposed to be carried up with the cooling air, but the temperature of freezing or zero degrees centigrade is soon attained—as the diagram shows—when the pressure is about 472 millimetres. At this point the special evolution of latent heat of freezing comes into play; and although the air rises higher and more moisture is condensed, the temperature does not fall because the water already converted into vapour and now becoming ice is giving out latent heat sufficient to counteract the cooling due to expansion. This illustration from Hertz's diagram therefore shows that the curve for cooling temperature coincides with the vertical line for freezing, and is represented on the diagram by the short piece $\beta \gamma$. By this expansion due to ascent the volume is increased while the temperature is not changed; therefore, the quantity of aqueous

FIG. 10.—Diagram for Graphic Method of following Adiabatic Changes. (After Hertz.)

vapour has increased. When the ascending mass has reached the level where the pressure is 463 millimetres it has also reached the moisture line that represents this increase in aqueous vapour. As this shows that the aqueous particles have now all been frozen, and as the air is now continuously rising, while its temperature is always below freezing-point, therefore at levels above this point the vapour that condenses from the air is supposed to pass directly over into the condition of solid ice. Therefore from this point onwards the falling temperatures follow along the line $\gamma \gamma$, and continue along it indefinitely. From these considerations it follows that the clouds above the altitude of freezing temperatures are essentially snow crystals, and if the air rises slowly there may be time for the water and ice to settle down towards the ground; in this case the quantity of snow left within the clouds must be very small, and the cloud has the delicate appearance peculiar to cirrus. Hertz's original diagram is quite covered by these systems of α , β , γ , and δ lines, and the moisture lines. The lines show the density of the moist air at any stage of the process. An improved diagram by Neuhoff was published in 1900.

In von Bezold's treatment of this subject only illustrative diagrams are published, because the accurate figures, drawn to scale, are necessarily too large and detailed. He presents graphically the exact explanation of the cooling by expansion, the loss of both mass and heat by the rainfall and snowfall, and the warmth of the

remaining air when it descends as foehn winds in Switzerland and chinook winds in Montana. Even in the neighbourhood of a storm, and over low lands and the ocean, the warm moist air in front, after being carried up to the rain or snow stage, descends drier and warmer on the opposite side of the central low pressure. In order to have a convenient term expressive of the fact that two masses of air in different portions of the atmosphere having different pressures, temperatures, and moistures, would, if brought to the same pressure, also necessarily attain the same temperature, von Bezold introduced the expression "potential temperature," and devised a simple diagram by which the potential temperature may be determined for any mass of air whose present temperature, pressure, and moisture are known. In an ascending mass of air, from the beginning of the condensation onwards, the potential temperature steadily increases by reason of the loss of moisture, but in a descending mass of air it remains constant at the maximum value attained by it at the highest point of its previous path. In general the potential temperatures of the upper strata of the atmosphere are higher than of the lower. In general the so-called vertical temperature gradient is smaller than would correspond to the adiabatic rate for the dry stage. This latter gradient is 0.993°C . per hundred metres for the dry stage, but the actual atmospheric observations give about 0.6° . Apparently this difference represents primarily the latent heat evolved by the condensation of vapour as it is carried into the upper layers, but it also denotes in part the effect of the radiant heat directly retained in the atmosphere by the action of the dust and the surfaces of the clouds. Passing from simple changes due to ascent and descent, von Bezold next investigated the results of the mixture of different masses of air, having different temperatures and humidities, or different potential temperatures. The importance of such mixtures was exaggerated by Hutton, while that of thermodynamic processes was maintained by Espy, but the relative significance of the two was first clearly shown by Hann as far as it relates to the formation of rain, and further details have been considered by von Bezold. The practical tables contained in Prof. Bigelow's report on clouds complete our methods of studying this subject.

A most important application of the views of von Bezold, Hertz, and Helmholtz was published by Brillouin in his memoir of 1898. Just as we have learned that the motions of the atmosphere are not due either to the general distribution of heat or to local influences exclusively, but in part to each, and just as we have learned that the temperature of the air is not due either to radiation and absorption or to dynamic processes exclusively, but to both combined, so in the phenomena of rain and cloud the precipitation is not always due to the cooling by mixture, or to the cooling by expansion, or to radiation, but is in general a complex result of all. The effect of the evaporation of cloudy particles in the production of descending cold currents has always been understood in a general way, but was first brought to prominence by Espy in 1838, and perhaps equally forcibly by Faye in 1875. Helmholtz, in his memoirs on billows in the atmosphere, showed how contiguous currents may interact on each other and mix together at their boundary surface; but Brillouin explains how these mixtures produce cloud and rain—not heavy rains, of course, but light showers, and spits of snow and possibly hail. He says: "When the layers of clear or cloudy air are contiguous, but moving with very different velocities, their motion, relative to the earth because of the rotation of our globe, assumes a much more complicated character than that which obtains when the air has no horizontal but only a vertical motion. We know in a general manner what apparent auxiliary forces must be introduced in order to take into account this rotation, and numerous meteorologists have published important works on the subject since the first memoirs by Ferrel. But their points of view have been very different from mine. The subjects that I desire to study are the surfaces of discontinuity as to velocity, temperature, and cloudiness in one special case only. Analytical methods permit us to resolve complex questions only for limited areas in longitude and for contiguous zones within which the movements are steady, but not necessarily uniform nor parallel. But it is evident that one can learn much as to the condition of permanence or destruction of annular zones having uniform and parallel movements. Thus simplified, the questions can be treated by elementary geometric methods, by means of which we at once rediscover and complete the results given by Helmholtz for zones of clear air and discover a whole series of new results for zones of cloudy air." Among Brillouin's results are the following theorems:—

A. If the atmosphere be divided into narrow zonal rings, each extending completely around the globe, thus covering a narrow zone of latitude, and if each is within itself in convective equilibrium so that the surfaces of equal pressure shall be surfaces of revolution around the axis of rotation, then within any such complete ring in convective equilibrium the angular velocity of any particle of the air will vary in inverse ratio of the square of its distance from the axis of rotation, or av^2 is constant; that is to say, the air will not move like a rotating solid, but will have a variable angular velocity, smaller far from the axis and greater near to it.

B. The surfaces of equal pressure are more concave towards the centre than is the surface of the globe itself, and they are tangent to the latter only along the parallel where calms prevail.

C. A heavy gaseous atmosphere resting upon a rotating frictionless globe divides itself into concentric rings whose angular movements increase as we pass from the polar region towards the equatorial ring; the central globe rotates more rapidly than the equatorial atmospheric ring.

D. The surface of separation between two contiguous concentric rings must be such that the atmospheric pressure shall have the same value as one approaches this surface from either direction, and the surface of separation is stable if the differences of pressure in different parts of this surface are directed towards the surface of equilibrium. As the distribution of pressure along a line parallel to the axis of rotation is independent of the velocity of rotation, the ordinary condition of stability, viz., that the gas of which the lower ring is composed shall be denser than that above, will hold good for this line. In general, any inclination of the surface of separation to the horizon amounting to 10° must be associated with very small differences of density and large differences of velocity; in practice the inclinations are far less than 10° .

E. If the surfaces of equal pressure or isobars are nearly horizontal, as in ordinary cases, the calculations are comparatively easy to make. Let the inclination of the isobaric surface ascending towards the pole be ϕ ; let h_1 be a distance counted along the axis of the earth, and H_1 the distance measured in the direction of the attraction of gravity; then the angle of inclination of the isobaric surface is given by the equation

$$\text{tang. } \phi = - \frac{H_1 - h_1 \sin \lambda}{h_1 \cos \lambda}$$

where λ is the complement of the angle between the direction of gravity and the line drawn to the poles, or the axis of rotation of the earth. The surface of separation is that over which the pressure is the same in two contiguous masses or zones, and is identical with a vertical plane only when the densities and velocities in the two layers have certain specific relations to each other. It can never lie between the isobaric surfaces that Brillouin designates as 1 and 2. In order that the equilibrium may be stable, it is necessary that when ascending in the atmosphere along a line parallel to the polar axis one should traverse layers of diminishing density. In the midst of any zone there cannot exist another zone of limited altitude; it must extend upwards indefinitely. Whenever there is any zone of limited altitude it must necessarily have, near its highest or lowest point, an edge by which it is attached to the surface of separation of two other neighbouring zones. In other words, the surfaces of separation of the three zones, of which one is limited and the other two are indefinite, must all run together at a common point or edge, very much as in the problem of the equilibrium of thin films.

F. When the contiguous zones are cloudless the mixtures take place under the following conditions:—Starting from the stable conditions, the cloudless mixture ascends on the polar side when the west wind which prevails on the equatorial side of the surface of separation is warmer, but descends between the pole and the equatorial side of the horizon when the west wind which prevails on the equatorial side of the surface of separation is colder. The mixtures of cloudless air rapidly occupy the whole height of the two layers that are mixing. When they form along a surface that becomes unstable the whirlwind that is thus engendered is sensibly cylindrical at first, but finally becomes extremely conical. This whirlwind may be limited as to height when the two contiguous masses that are mixing are surmounted by a third clear or cloudy layer which intersects the other two and whose lower surface is stable. (Brillouin suggests that possibly this corresponds to the formation of water-spouts and tornadoes.)

G. When the contiguous zones are cloudy and the mixtures produce decided condensations, and sometimes even precipitation, the study of these must follow closely in the train of thought followed out by von Bezold. When the contiguous winds are feeble, but the temperatures are very different and the zones are near the equator, then the position of the mixture can be inverted by condensation, since the influence of difference of pressure becomes predominant. At the equator, whatever may be the difference of temperature, a mixture that is accompanied by condensation always rises if the surface of separation is stable. The condensation increases by the expansion, each zone of mixture being an outburst of ascending cumuli. At the equator, whatever may be the difference of temperature, a mixture accompanied by condensation always descends when the surface of separation is unstable; moreover, the adiabatic compression rapidly evaporates the mixture.

In the last three chapters of his memoir, Brillouin applies these

principles and other details to almost every observed variety of mixtures due to the pressure of one current of air against another. Fig. 11, prepared for the *U.S. Monthly Weather Review*, October 1897, gives five of the cases elucidated by Brillouin. In each of these the left-hand side of the diagram is the polar side, the air being cold above and the wind from the east, while the right-hand side is the equatorial side, the air being warm above and the wind from the west. The reader will see that in each case, depending on the relative temperatures and winds, layers of cloud are formed of marked individuality. As none of these clouds appear in the *International Cloud Atlas* or the various systems of notation for clouds, one is all the more impressed with the importance of their study and the success with which Brillouin has opened up the way for future investigators. "We have no longer to do with personal and local experience, but with an analytical description of a small number of characteristics easy to comprehend and applicable at every locality throughout the globe."

The Formation of Rain.—Not only has dynamic meteorology made the progress delineated in the previous sections, but one of the most important questions in molecular physics is in rapid process of being cleared up. The formation of rain, from a physical point of view, is the ultimate step in the formation of cloud. The cloud consists, like fog, of extremely small particles, so light that they float indefinitely in the air; rain and snow represent those particles that have grown to be too large and heavy to be any longer sustained by the air—that is to say, their rate of fall through the air is greater than the ascending component of the air in which they float. The process by which such larger rain-drops are formed out of the lighter particles that constitute a cloud has not yet been satisfactorily explained. It is probable that either one of several processes contributes to bring about this result, and that in some cases all of these conspire together. The following paragraphs represent the hypotheses that have marked the gradual progress of our knowledge:—

A. Cloud particles may be driven together by the motions imparted to them by the wind, and may thus mechanically unite

FIG. 11.—Diagram illustrating Clouds due to Mixture. (After Brillouin.)

into larger ones, which, as they descend more rapidly, overtake the smaller ones and grow into rain-drops.

B. The particles on the upper boundary of a cloud may at night-time, or in the shade, cool more decidedly than their neighbours below them, either by radiation or by mixture; then the air in their immediate vicinity becomes correspondingly cold, the particles and their envelopes of cold air sink more rapidly, overtaking and therefore uniting with other particles until the large rain-drops are formed.

C. Some cloud particles may be supposed to be electrified positively and others negatively, causing them to attract each other and run together into larger ones, or, again, some may be neutral and others charged, which may also bring about attraction and union.

D. When any violent agitation of the air, such as the sound

waves due to thunder, or cannonading, or other explosions, sets the particles in motion, they may be driven together until brought into contact, and united into larger drops.

E. The air—or, properly speaking, the vapour—between cloudy particles, that is to say, within fog or cloud, is generally in a state of supersaturation; but if it is steadily rising to higher altitudes, thereby expanding and cooling, the supersaturation must increase steadily until it reaches a degree at which the molecular strain gives way, and a sudden violent condensation takes place, in which process both the vapour and the cloud particles within a comparatively large sphere are instantaneously gathered into a large drop. The electricity that may be developed in this process may give rise to the lightning flash, instead of the reverse process described in the preceding paragraphs (C and D), by which the lightning and the thunder either change the electrical conditions or cause noises and concussions that lead to the formation of rain.

F. However plausible the preceding five hypotheses have seemed to be, it must be confessed that no one has ever yet observed precipitation actually formed by these processes. The laborious observations of Mr C. T. R. Wilson of Cambridge, England, probably give us our first correct idea as to the molecular processes involved in the formation of rain. After having followed up the methods inaugurated by Aitken showing that the particles of dust floating in the air, no matter of what they may be composed, become by preference the nuclei upon which the moisture begins to condense when air is cooled by expansion, Wilson then showed that in absolutely dustless air, having therefore no nuclei to facilitate condensation, the latter could only occur when the air is cooled to a much greater extent than in the case of the presence of dust; in fact, dustless air requires to be expanded more than dusty air in the ratio of 4 to 3, or $1\frac{1}{3}$ times more. The amount of this larger expansion may vary somewhat with the temperature, the moisture, and the gases. More remarkable still, he showed that dustless air, having no visible or probable nuclei, acquired such nuclei when a beam of ultra-violet light, or of the Röntgen rays, or the uranium radiation, or of ordinary sunlight (which possibly contains all of these radiations), was allowed to pass through the moist air in his experimental tube. In other words, these rays produce a change in the mixed gas and vapour similar to the formation of nuclei, and condensation of aqueous vapour takes place upon these invisible nuclei as readily as upon the visible dust nuclei. Further, the presence of certain metals within the experimental tube also produces nuclei; but the amount of expansion, and therefore of cooling, required to produce condensation upon these metallic nuclei is rather larger than in the case of dust nuclei. The nuclei thrown into the experimental tube by the discharge of electricity from a pointed metal wire produced very dense fogs by means of expansions slightly exceeding those required for ordinary dust. Finally, Wilson has been able to show that when dust particles are electrified negatively their tendency to condense vapour upon themselves as nuclei is much greater than when they are electrified positively, and he suggests that the descent of the rain-drops to the ground, carrying negative electricity from the atmosphere to the earth, may perhaps explain the negative charge of the earth and the positive electricity of the atmosphere.

At this point we come into contact with the views developed by J. J. Thomson as to the nature of electricity and the presence of negative and positive nuclei in the atmosphere. According to him, "The molecules made up of what chemists call atoms must be still further subdivided, and the atoms must be conceived as made up of corpuscles; the mass of a corpuscle is the same as the mass of the negative ion in a gas at low pressure. In the normal atom this assemblage of corpuscles forms a system which is electrical and neutral. Though the individual corpuscles behave like negative ions, yet when they are assembled in a neutral atom the negative effect is balanced by something which causes the space through which the corpuscles are spread to act as if it had a charge of positive electricity equal in amount to the sum of the negative charges on the corpuscles. I regard electrification of a gas as due to the splitting up of some of the atoms of the gas, resulting in the detachment of a corpuscle from such atoms. The detached corpuscles behave like negative ions, each carrying a constant negative charge which we shall call the unit charge, while the part of the atom left behind behaves like a positive ion with the units positively charged, but with a mass that is large compared with that of the negative ion. In a case of the ionization of the gas by Röntgen or uranium rays, the evidence seems to be in favour of the view that not more than one corpuscle can be detached from any one atom. Now the ions by virtue of their negative charges act as nuclei around which drops of water condense when moist dust-free gas is suddenly expanded. . . . Mr C. T. R. Wilson has shown that it requires a considerably greater expansion to produce a cloud in dust-free air on positive ions than on negative ones, when the ions are produced by Röntgen rays." It would therefore appear that the moist atmosphere above us may, through the action of sunlight, as well as by other means, become ionized. The negative ions attract moisture to themselves more readily than the positive; they grow to be larger drops, and

descending to the earth with their negative charges give it negative electricity, while the atmosphere is left essentially either positive or neutral. (See also ATMOSPHERIC ELECTRICITY.)

METEOROLOGICAL ORGANIZATIONS.

During the latter half of the 19th century the prosecution of work in meteorology gradually passed out of the hands of individuals into the control of large national organizations. This was the natural result of the discovery that, by the spread of the electric telegraph and ocean cables, it had become possible to compile daily weather maps for large portions of the globe and make predictions of the weather and the storms for a day or two in advance, of sufficient accuracy to be of the greatest importance to the material interests of civilized nations. One by one every civilized nation has established either a weather bureau or a meteorological office, or a bureau of hydrography and marine meteorology, according as its special interests demanded. These governmental bureaux usually pursue both climatology and theoretical meteorology in addition to their daily practical work of telegraphy, forecasting, and publication of charts. Although, of course, in most cases, the so-called practical work absorbs the greater part of the labour and the funds, yet everywhere it is recognized that research and the development of a correct theory of the motions of the atmosphere are essential to any important progress in the art of forecasting. Among other important works in which the official weather bureaux have united, we may enumerate the International Meteorological Congresses, of which the first was held in 1853 at Brussels, the second in 1873 at Vienna, and others more frequently since that date; the establishment of an International Committee, to which questions of general interest are referred; the organization of a systematic exploration of the polar regions in the years 1882 and 1883; the general extension of the meteorological service to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the general co-operation with the U.S. Weather Bureau in the contribution of data for its international bulletin and its daily map of the whole northern hemisphere. The hydrographic offices and marine bureaux of the principal commercial nations have united so far as practicable in the daily charting of the weather, but have especially developed the study of the climatology of the ocean, not only along the lines laid down by Maury and the Brussels Conference of 1853, but also with special reference to the tracks of storm centres and the laws of storms on the ocean. The present condition of these governmental organizations is well presented in the annual address of the Hon. F. Campbell Bayard, delivered before the Royal Meteorological Society of London in January 1899, and in the text accompanying Bartholomew's *Physical Atlas*, vol. iii.

The development of meteorology, in both its scientific and its practical aspects, is intimately dependent upon the progress of our knowledge of physics, and its study offers innumerable problems that can be solved by proper combinations of mathematical theory and laboratory experimentation. The professors in colleges and universities who have hitherto lectured on this subject have not failed to develop some features of dynamic meteorology, although most of their attention has been given to climatology. In fact, many of them have been engrossed in the study of general problems in molecular physics, and could give meteorology only a small part of their attention. The early text-books on meteorology were frequently mere chapters or sections of general treatises on physics or chemistry. The most prominent early cases of university professorships almost wholly devoted to meteorology are

those of the eminent Prof. Quetelet at Brussels and Prof. Kaemtz at Dorpat, Russia. In modern times we may point to Prof. von Bezold at Berlin, Prof. Hann at Vienna and Gratz, Prof. Pernter at Linz and Vienna, Prof. Woeikof at St Petersburg, Profs. Hildebrandsson at Upsala, Mohn at Christiania, Loomis at New Haven, and Davis and Ward at Cambridge, Mass. With these and a few other exceptions, the great universities of the world have as yet given but little special encouragement to meteorology; it has even been stated that there is no great demand for higher education on the subject. On the other hand, the existence of thousands of voluntary observers, the profound interest in the weather actually taken by every individual, and the numerous schemes for utilizing our very limited knowledge of the science through the activities of the large weather bureaux of the world demonstrate that there is a demand for knowledge perhaps even higher than the universities can offer. It would be very creditable to a nation or to a wealthy patron of science if there should be established meteorological laboratories in connexion with several important universities, at which not only instruction but especially investigation might be pursued, as is done at the magnificent astronomical observatories that are to be counted by hundreds throughout the world. The great difficulties inherent in meteorology should stimulate the devotion of the highest talent to the progress of this branch of science. The practical value of weather predictions justifies the expenditure of money and labour in order to improve them in every detail.

(C. A.)

Method of Differences. See INTERPOLATION.

Methodism.—Since 1882 there have been two Methodist movements of world-wide importance: the "Forward Movement," and Methodist Reunion. The forward movement originated in the fact that sanctuaries in the crowded centres of modern cities were being gradually abandoned, while the majority of the people were outside all churches. The problem was solved in Manchester, where an almost abandoned sanctuary was reconstructed and immediately filled. The Manchester example has been followed in London, Leeds, Birmingham, Hull, Glasgow, and Edinburgh, and will be followed in the principal cities in the United Kingdom. The agencies are adapted to the actual human environment, great

variety of method exists, and marked features of the work are the combination of social enterprises with individual evangelism, and the organization of sisterhoods. The second notable movement is the growing tendency towards the reunion of the various Methodist churches. The true inwardness of the terrible struggles which so greatly injured British Methodism in the first half of the 19th century had never been clearly stated to the public until 1898, when Dr Benjamin Gregory published *Side Lights on the Conflicts of Methodism* (Cassell and Co.), which must determine the attitude of all future historians of Methodism. The possibility of such conflicts has now passed away. In 1878 laymen were admitted into the Conference, and from that time have taken an equal share in the settlement of all questions of "policy and finance." By the wish of the laymen themselves, doctrinal issues, the appointment of ministers, and all questions of discipline are left to the pastoral session. After much further controversy, it was resolved in 1900 that the representative session should henceforth meet before the pastoral session, and also be enlarged to 300 ministers and 300 laymen. This growing liberalism of the parent Conference has brought Methodist reunion, even at home, within the range of possibility. In Canada all branches of Methodism have been united. A similar movement is being consummated throughout Australasia. The British and American Methodist Churches in Germany, Switzerland, Austria, and Hungary have also been united. The day is evidently not very far distant when Great Britain will follow the example of her colonies. The present ideal of most enlightened Methodists is one Methodist Church in every country, and an oecumenical conference every ten years to bind them all together. Three such conferences have already been held: in London in 1881, in Washington in 1891, and in London in 1901. The quadrennial general conference of the Methodist Episcopal Church in 1900 reached three ecclesiastical decisions of importance—for the future there will be an equal number of ministerial and lay representatives, the time limit has been abolished, and women as well as men may be elected lay representatives. The most authentic available statistics of Methodism are those presented to the second oecumenical conference in Washington in 1891. A special statistical committee collected the facts from all Methodist Churches throughout the world. The following is a summary:—

Summary of Geographical Distribution.

Continents.	Ministers.	Local Preachers.	Churches.	Other Preaching Places.	Members.	Sunday Schools.	Sunday School Teachers.	Sunday School Scholars.	Adherents.
Europe	4,488	39,748	15,584	3503	915,896	14,405	243,748	1,781,612	4,212,601
Asia	602	356	326	34	35,314	282	1,944	47,430	118,968
Africa	365	2,146	571	1264	77,234	450	2,669	28,267	295,376
America (<i>see also below</i>)	39,042	51,578	57,465	...	5,382,375	62,323	593,246	4,579,539	19,784,293
Australasia and Polynesia	786	5,375	3,250	2138	93,140	3,828	19,785	197,314	488,183
Total for churches represented at the Conference as far as reported	45,283	99,203	77,196	6939	6,503,959	81,288	861,392	6,634,162	24,899,421

As the advance during the decade 1880 to 1890 amounted to 30 per cent., and as the ratio of growth continually increases, the total number of Methodist adherents throughout the world must in 1900 have exceeded thirty millions.

(H. P. H.)

United States.—The first oecumenical Methodist Conference, held in London in 1881, greatly broadened the views of its members, and especially increased the spirit of fraternity among American Methodists. This found expression in the centennial Methodist Conference, which in 1884 celebrated the one hundredth anniversary of the

organization of American Methodism into a church. The second oecumenical Conference, in Washington in 1891, equalled its predecessor in influence and interest. These events materially modified the extent and form of the development of American Methodism. The spirit of fraternity has been illustrated and increased by the establishment of the Epworth League, which was formed in May 1889 by representatives of five of the largest Young People's societies in the Methodist Episcopal Church, and has spread to other Methodist denominations until there are 1,860,000 members. The Woman's Home Missionary Society, which was formed in 1881, has greatly increased

its membership, enlarged its revenue, and expanded its work. In the conduct of a training-school in Chicago the need of a deaconess was felt; the office had been introduced into the Methodist Church in Germany; and memorials from the Conference, including Chicago and other cities near it, were sent to the general Conference asking for the authorization of deaconesses. These memorials were greatly reinforced by a similar memorial from Bengal in India, showing the imperative necessity of deaconesses to the highest success of the mission. Provision was made for their establishment in 1888. The same institution has been established in other Methodist denominations, especially in the Methodist Episcopal Church, South, and with it are connected prosperous hospitals; and generous bequests and benefactions have been made to that class of institutions which also exist independently. Philanthropic institutions, such as orphan asylums, children's homes, and homes for the aged, have relatively absorbed a large part of the energies and beneficence of Methodism, particularly of its women. The first Methodist Episcopal hospital in American Methodism, founded some years before, was opened in Brooklyn, and the next in Philadelphia in 1892. So rapidly has this movement spread that there are more than thirty general hospitals under Methodist auspices.

The Methodist Episcopal Church, South, established equal ministerial and lay representation in 1866, in the general Conference, and lay representation in the annual Conference, in the proportion of four for each presiding elder's district. The Methodist Episcopal Church in 1872 introduced lay representation, limiting the number of laymen to one for each Conference having but one ministerial delegate, and in all other Conferences to two, whatever the number of ministerial delegates. From time to time efforts have been made to remove this limitation so as to make the representation equal. This involved a change in the constitution, which can be accomplished only by a vote of three-quarters of the members of the annual Conferences and a two-thirds vote of the general Conference. The first condition having been complied with by the ministers, and the second by the general Conference in May 1900, the restrictive rule was altered, and laymen, selected to be in readiness, were admitted to seats. The Methodist Episcopal Church, South, has largely increased its contributions for missions, for Church extension, and for denominational education. Since the overthrow of Spanish rule in Cuba it has established a mission in that island, and in the spring of 1900 had a number of workers in the field. The contributions for missions of the Methodist Episcopal Church have increased since 1884 from \$813,269 per annum to \$1,864,325 in 1901, and its missions, in number of societies and members, in proportion. The missionary enterprises of all Methodist denominations in nearly all pagan lands have prospered, prejudices melting away and converts becoming so numerous as to outrun the provisions for their training and organization. The Woman's Foreign Missionary Societies have contributed in very large measure to these results. In the Methodist Episcopal Church a controversy has prevailed on the eligibility of women to membership in the general Conference. Several in 1888 and 1896 appeared with credentials in due form; thus far the question is unsettled, some opposing on principle and expediency, more on the ground that the constitution must first be changed. Two ineffectual efforts have been made to do this. The constitution of the Methodist Episcopal Church has been entirely revised since 1900, and women are now eligible to seats in the general Conference. The changes made in the polity of the Methodist Episcopal Church, South, in 1866, were so radical that there has been no disposition since, or at most no widespread desire, to do more. Occasionally a few, who meet with little support, advocate the abolition of the life tenure of the bishops, or propose radical modifications in the presiding eldership. The Methodist Protestant Church, the largest non-episcopal body, is constantly raising the standard of its ministerial qualifications and the grade of its preparatory schools and colleges. It has revised its hymnal and its discipline, restricted its church boards, and has had the satisfaction of seeing lay representation (the chief reform advocated by its founders) adopted by those who rejected their propositions. At the general Conference of 1884 the rule limiting a continuous pastorate to five years was abolished, and a rule adopted giving each annual Conference authority to decide for itself whether there should be any limit, or, if any, what it shall be. The overture sent down to the Conferences authorizing the ordination of women to the ministry, after much discussion and agitation, was rejected. The Wesleyan Methodist body, formed in 1843, though small, has a strong denominational spirit, and is true to its fundamental and somewhat exclusive

principles. These were tested in 1895, when the Church refused to modify the rules relating to secret societies, dress, and furniture, though an important Conference threatened disloyalty if it was not done. They declared that on this question as a unit they would survive or perish, and decided that, however few the members that adhered to a Church in case of a rebellion, they should constitute the Church and hold the Church property.

The African Methodist Episcopal Church has extended its missions into British, French, and Dutch Guiana, Trinidad, St Thomas, Hayti, Liberia, and Sierra Leone. This body has devoted itself to education with extraordinary zeal and success, and for this purpose it has raised within a few years above \$1,000,000. At the Conference of 1884 of the African Methodist Episcopal Zion Church the word "male" was struck out from the Discipline, so that the sexes are equally eligible to all positions, lay and clerical. It has been constantly growing in numbers and in zeal for missions, education, and churchly order.

Statistics of American Methodists (1899).

Methodists.	Ministers.	Churches.	Communicants.
1. Methodist Episcopal	16,771	26,424	2,762,691
2. Union American Methodist Episcopal	175	200	16,200
3. African Methodist Episcopal	6,179	5,715	698,354
4. African Union Methodist Protestant	63	73	2,608
5. African Methodist Episcopal Zion	3,475	2,955	537,337
6. Methodist Protestant	1,647	2,401	184,097
7. Wesleyan Methodist	699	506	16,496
8. Methodist Episcopal, South	6,166	14,479	1,477,180
9. Congregational Methodist	345	350	21,000
10. Congregational Methodist (Coloured)	5	5	319
11. New Congregational Methodist	192	366	4,000
12. Zion Union Apostolic	30	32	2,346
13. Coloured Methodist Episcopal	2,061	1,433	204,972
14. Primitive	68	100	6,834
15. Free Methodist	1,003	1,034	27,487
16. Independent Methodists	8	15	2,569
17. Evangelist Missionary	48	13	2,010
Total Methodists	38,935	56,101	5,966,500

(J. M. BU.)

Metković, or **МЕТКОВИЧ**, a market-place and seat of the administration of the government district of the same name in the Austrian crownland of Dalmatia. It is situated near the frontier of Herzegovina, on the Narenta river, navigable thus far, and has since the Austrian occupation been the chief depôt for imports to Herzegovina. It is a railway and steamship station. Population (1890), 4198; (1900), 4878, chiefly Serbo-Croatians.

Metz, a town, first-class fortress, and episcopal see of Germany, in Alsace-Lorraine, capital of (German) Lorraine, on the Moselle, 99 miles north-west of Strasburg by rail, and 10½ miles east of the French frontier. The strength of the fortifications now lies chiefly in the ring of detached modern forts, two to three miles distant from the town. Its garrison, a mixed body of Prussians, Saxons, and Bavarians, numbers 22,000 men. The cathedral (Roman Catholic) has been undergoing restoration since 1875. The town hall (1771) contains a small museum (this is in addition to the library museum). A fine equestrian statue of the Emperor William I. (1892) adorns the esplanade, and a bronze statue of Prince Frederick Charles (1898) the adjacent Boufflers garden; and there are also statues to Generals Ney (1855) and Fabert. The noteworthy public buildings and institutions include also the law courts, episcopal palace, provincial administrative offices, the arsenal, military school, music school, teachers' seminaries, theological seminary, deaf and dumb asylum, glass-painting school, &c. Except for tanneries, leather factories, and ironworks, there is relatively little industry. Since

the war of 1870-71 Metz has been visited annually by great numbers of people desirous of seeing the famous battlefields of the former year—that is, Gravelotte, St Privat, Rezonville, and Vionville, on the west (battles of 16th and 18th August), Colombey and Nouilly on the east (14th and 31st August and 1st September), and Woippy, where Bazaine made his last attempt to break through on 7th October. The capitulation was signed at the château of Frescati, about three miles south of Metz. Population (1885), 54,072; (1900), 58,424.

Meudon, a town in the arrondissement of Versailles, department of Seine-et-Oise, France, 6 miles east of Versailles by rail. The remains of a castle, burned by the Germans in 1871, have since been adapted for an observatory of astronomical physics, connected with which is an important magnetic observatory, installed in a modern high tower. The handsome Galliera Institutions, on the hill of Fleury, were founded by the duchess of Galliera for the reception of 100 aged persons and 350 orphans. The buildings were completed in 1885 at a cost of £560,000, and provided with an endowment of £400,000. Meudon is the seat of extensive manufactures of munitions of war for the artillery, and in the neighbouring park of Chablais is the Government establishment of military ballooning. Population (1891), 7258; (1901), 9702.

Meurthe-et-Moselle, a department of the east of France, bordering on German Lorraine, watered by the two rivers naming it.

Area, 2037 square miles. The population, 419,317 in 1881, had increased to 484,002 in 1901. Births in 1899, 11,044, of which 1054 were illegitimate; deaths, 9888; marriages, 3479. There were in 1896, 1055 schools, with 66,000 pupils, the illiterate forming 2 per cent. of the population. Out of 1,218,272 acres in 1896 of cultivated land, 635,084 acres were plough-land and 39,530 acres vineyards. The produce of wheat in 1899 was valued at £814,000; oats, £524,000; potatoes, £432,000, mangold-wurzel, £121,000. The natural pastures returned the value of £368,000; hops, £51,000. The live stock of 1899 included 51,240 horses, 91,590 cattle, 115,100 sheep, and 88,620 pigs. Meurthe-et-Moselle takes precedence of all the other departments of France for iron-mining, its production in 1898 amounting to 3,804,000 metric tons, of the value of £445,000, and constituting four-fifths of the total production of France. It further extracted 508,000 metric tons of rock-salt, valued at £202,000. Metallurgy is highly advanced, forming the chief wealth of the department. In 1898 it produced 1,645,000 metric tons of cast-iron, 50,500 tons of iron, and 158,000 tons of steel, totalling altogether the value of £4,410,000. Distilleries manufactured, in 1896, 110,048 gallons of alcohol. Glass-works, peltry, and spinning also occupy many lands. Nancy, the capital, had 102,463 inhabitants in 1901.

Meuse, a department in the north-east of France, watered by the Meuse.

Area, 2409 square miles. Population, 289,861 in 1881; 283,136 in 1901. Births in 1899, 5477, 324 of them illegitimate; deaths, 5985; marriages, 1821. There were in 1896, 900 schools, with 40,000 pupils, the illiterate composing 2 per cent. of the population. Out of 1,457,300 acres of cultivated land in 1896, 810,160 acres were plough-land and 22,230 acres vineyards. The wheat crop of 1899 amounted to the value of £981,000; barley, £104,000; oats, £640,000; vines, £268,000; potatoes, £342,000; mangold-wurzel, £108,000. The live stock in 1898 included 47,000 horses, 103,480 cattle, 124,680 sheep, and 75,210 pigs. The department is not rich in minerals, yet its industry in metals produced in 1898, 9000 metric tons of iron and 8700 tons of steel, valued at £108,000. Distilling yielded 101,000 gallons of alcohol. There is also a brisk industry in sugar-refining. Bar-le-Duc, the capital, had 17,693 inhabitants in 1901.

Meuse (Dutch *Maas*; Flemish, *Maes*), a river rising in the department of Haute-Marne, France, 16 miles north-east of Langres, and after pursuing an extraordinary course through France, Belgium, and Holland, falling into the North Sea about 52°. In the department of Vosges the river disappears underground between Bazeilles and Noncourt, a distance of 3½ miles. In Belgium it has been

canalized from Liège to Visé, close to the German frontier, as has also the lower course of the Ourthe, which joins the Meuse at Liège. In Holland the distance between Maas-tricht and Eindhoven has been reduced from 144½ to 75½ miles by means of the South Willems canal; and below Mook, where the banks are low, the Meuse is confined by dykes. But, as a means of safety, portions of the river are left undyked, so that at high flood the water overflows the low lands of Grave, Bois-le-Duc, and the Langstraat. To obviate the inconveniences of these inundations, the mouth of the Maas was diverted in 1883 into a new channel. Starting at Hedikhuizen, the new course runs westwards, follows the line of the Old Maas, and issues into the Amer, and thence into Hollandsch Diep, where the level is lower than that of the confluence of the Waal and the Maas at Loevenstein. By this new regulation the Maas will discharge its waters by mouths nearly identical with those of its earlier history. The new channel thus provided has a breadth of 1640 feet. Total area of river basin, 18,530 square miles; length, 500 miles; breadth at Verdun, 213 feet; at Namur, 426 feet; at Liège, 656 feet; at Gorinchem (Gorkum), 1066 feet. (See also HOLLAND: *Rivers and Canals*, and ROTTERDAM.)

Mexborough, a town in the Doncaster parliamentary division of Yorkshire, England, on the Don, 5½ miles north-north-east of Rotherham, and on the Great Central railway. It has potteries and ironworks. Population (1881), 6319; (1891), 7734; (1901), 10,417.

Mexico, or the UNITED STATES OF MEXICO, lying between the United States of America on the north and Guatemala on the south, extending from 14° 30' 42" to 32° 24' N., and from 86° 46' 08" to 117° 07' 31" W. The boundary towards the United States, determined generally by treaties of 1848 and 1853, has in disputed localities been demarcated in accordance with conventions of 29th July 1882 and 18th February 1889, but this precise delimitation is not yet complete. Towards Guatemala the boundary was fixed by treaties of 27th September 1882

States and Territories.	Area. Sq. miles.	Population (1895).	Population (1900).	Density per sq. mile in 1900.

and 1st April 1895. Towards British Honduras the boundary runs in a course defined by treaty of 8th July 1893, from the mouth of the Bocalarichica, the strait between Yucatan and Ambergris Cay, to the boundary between Mexico and Guatemala.

On an area of about 767,000 square miles Mexico contained in 1895 a population of 12,632,427, and in 1900, of 13,545,462. The area and the census population of the Federal District, and of each of the 27 states and 2 territories, are given in the table on the preceding page. (The total area given in the table is exclusive of the coast islands, covering altogether about 1420 square miles.) The population consisted in 1900 of 6,716,007 males and 6,829,455 females. Of the total in 1895, 19 per cent. were of white race, 43 per cent. Indian, and 38 per cent. mixed. The prevailing language is Spanish, but Indian languages were in 1895 spoken by 2,034,712 inhabitants, and foreign languages by 22,972. The number of foreigners resident within the republic in the same year was 49,698, the nations most numerously represented being Guatemala, 12,333; Spain, 12,228; North America, 10,222; France, 3763; Great Britain, 3384; Germany, 2337; Italy, 1574; China, 987. The population, classified according to occupation, was as follows:—

Professional (teachers, doctors, &c.)	38,081
Students and school children	635,365
Public services	57,488
Agricultural and pastoral	2,935,070
Mining	80,158
Commercial	205,942
Proprietors	38,560
Industries and arts	681,974
Various (household servants, &c.)	1,562,362
Without occupation	2,831,363
Children	3,255,052
Occupation unknown	310,143
Total	12,631,558

The registration of births, deaths, and marriages was begun in 1893, but the results annually published do not appear to be trustworthy. For 1898 the registered births numbered 489,933; deaths, 452,238; marriages, 61,687. The chief cities and towns of Mexico are the following:—Mexico, 329,774; Puebla, 88,684; Guadalajara, 83,934; San Luis Potosi, 69,050; Leon, 58,426; Monterey, 45,695; Pachuca, 40,487; Zacatecas, 39,912; Guanajuato, 39,404; Merida, 36,935; Queretaro, 34,576; Morelia, 33,890; Oaxaca, 32,437; Orizaba, 31,512; Aguascalientes, 30,872; Saltillo, 26,801; Durango, 26,425.

Constitution and Government.—The constitution in force in Mexico in 1902 was originally promulgated 5th February 1857, and has been frequently amended. It declares that the Mexican Republic, established under the representative, democratic, and federal form of government, consists of states free and sovereign in everything relating to their internal administration, but united in a federation for common interests. Among the provisions of the constitution may be noted that which restricts military authority in time of peace to the functions connected with discipline, that which declares the Church and the State to be separate, and that which makes marriage a civil contract.

Legislative.—The legislative power is vested in a General Congress of two chambers. The Senate consists of two senators (each with an alternate) from each state and the Federal District, elected indirectly by the people for a term of four years. They must be at least thirty years old, in the enjoyment of all their civil rights as Mexican citizens, be residents of the states which they represent, and not be in ecclesiastical orders. Federal office-holders are ineligible. The deputies are elected in the

same manner as the senators, but in the proportion of one deputy for every 40,000 inhabitants or fraction over 20,000. Their term of office is two years, and an alternate is elected for each deputy. Deputies must be at least 25 years of age. In 1897 there were 227 deputies. Members of both houses are paid £300 a year. Electors are all Mexicans possessing honest means of livelihood, and, if married, being over 18 years of age; if unmarried, over 21. The Congress has two ordinary sessions: the first begins on 16th September and ends 15th December; the second is held from 1st April to 31st May. During the recesses a standing committee of 15 deputies and 14 senators, selected by the respective chambers, is endowed with limited legislative functions.

Executive.—The President of the United Mexican States is elected for four years by electors chosen by the people. His term of office commences on the 1st of December after election. He may be re-elected indefinitely (Amendment to Constitution, 20th December 1890). In case of his death, or permanent disability, a provisional President is elected by Congress to hold office until an election can be held in the usual manner. Temporary vacancies in the Presidency are filled by the Secretary of State. The President must be a native-born Mexican possessing full civil rights, must be at least 35 years of age, must not belong to any ecclesiastical order, and must be resident in the country at the time of election. He is assisted in the discharge of his duties by a cabinet composed of seven secretaries, who are heads of departments of foreign relations; of finance and public credit; of communications and public works; of promotion, colonization, and industry; of interior; of justice and public instruction; of war and navy. Secretaries must be native-born citizens at least 25 years of age.

Judicial Power.—The Supreme Court contains 11 justices and 4 alternate justices, an attorney-general, and a public prosecutor, elected by the people indirectly in the same manner as senators and deputies, and for a term of six years. There are 3 circuit courts and 32 district courts.

Local Government.—The government of the states under the constitution is republican, representative, and popular. Legislative power in most of the states is vested in a congress of one chamber, the members of which are called deputies, and are in most states elected by indirect popular vote for a term of two years. The subject-matter of state legislation includes all that is not expressly given to the Federal authority. It was only in 1883 that an Act was passed for the unification of the mining and commercial legislation within the republic. The executive power is vested in a governor elected for four years, and the states have their own courts of justice. For administrative purposes they are divided usually into districts governed by a prefect. The smaller divisions are municipalities, the local authority being a town council (*ayuntamiento*).

Religion.—In 1895 over 99 per cent. of the population belonged to the Roman Catholic faith. The number of Protestants was 42,259; of Mormons, 1560; Mahommedans, Buddhists, and others, 804; of no professed religion, 62,560; and of unknown religion, 6847.

Instruction.—The condition in 1895 with respect to education is indicated by the following figures:—

Able to read and write	1,817,414
Able to read only	328,007
Able neither to read nor write	8,094,520
Young children (untaught)	2,351,100
Unknown	40,517
Total	12,631,558

Education is gratuitous, obligatory, and lay. Under an Act, passed 14th May 1896, official primary instruction in the Federal

District and in the territories is under the control of the executive. In the states the schools are maintained either from state funds or municipal funds. The school system comprises primary elementary, primary superior, and preparatory schools, the last being institutions for professional or technical instruction. Besides primary and normal schools, the Federal Government supports schools of jurisprudence, of agriculture and veterinary art, of engineering, of fine arts, of trades and arts for men and for women, of commerce and administration, a national conservatory of music, a preparatory school, schools for the blind and for deaf mutes, reformatory schools, &c.; also museums, and 17 libraries containing from 400 to 159,000 volumes.

In 1898 the number of schools was as follows:—Federal and state schools, 6738; municipal, 2953; private, 2158; Church, 346; association, 163; total, 12,358. In 1899 the total number of schools was 11,925 (6376 federal and state schools). At the federal, state, and municipal schools in 1899 there were 15,505 teachers and 684,563 enrolled pupils, the average attendance being 474,622; at the other schools the enrolled pupils numbered 134,987, and the average attendance 103,955. The amount spent on federal, state, and municipal schools in 1899 was £680,500.

Within the republic, in 1899, there were 33 museums, 139 libraries, with an aggregate of 992,000 volumes, and 39 scientific and literary societies. The number of periodical publications was 702—18 being in English, 11 in English and Spanish, 3 in French, and 1 in German. The daily papers numbered 55; weekly, 242; monthly, 85; others being published at various other intervals.

Crime.—Criminal statistics for the whole republic are not published; those for the Federal District showed that, in 1897, 14,512 persons (11,487 males and 3025 females) were tried for crimes or misdemeanours, and 8108 were convicted. The convictions comprised 5830 cases of assault, 1230 of theft, and 102 of homicide.

Finance.—The federal revenue is derived chiefly from import duties and internal taxation, and the most important branches of expenditure are the public debt, the army and navy, and public works. For each of the years specified the amount of revenue and of expenditure (estimated for 1902-03) has been as follows, the dollar being taken at two shillings:—

Year.	Revenue.	Expenditure.
1896-1897	£5,150,062	£4,833,050
1899-1900	6,426,100	5,830,990
1902-1903	6,482,360	6,473,880

The foreign debt of the republic consists mainly of the 5 per cent. external consolidated gold loan contracted in 1899 for the conversion of prior loans. The original amount was £22,700,000, of which, in the middle of 1901, £22,479,660 was outstanding. The whole debt is redeemable, not later than the year 1945, by a sinking fund secured on the national import and export duties. The external silver currency bonds of 1890 have been nearly all redeemed; the outstanding amount in 1900 was about £11,400. The internal debt amounts to \$121,824,750, or about £12,182,475; and the floating debt to \$1,015,836, or about £101,540. The fiscal value of property within the republic in 1899 was—urban, £35,052,370; rural, £42,394,780; total, £77,447,150, the fiscal value being taken at one-third less than the actual value. The revenues of the Mexican states vary within narrow limits, while their expenditures on the whole show a considerable decrease. The revenue and expenditure of the municipalities show a considerable increase within the five years ending 1899, when the annual aggregates of these local revenues and expenditures were:—

States	Revenue.	Expenditure.
States	£1,995,250	£1,969,590
Municipalities	1,652,250	1,591,970

Army.—The military forces consist of the active army and the reserve, in one or other of which every Mexican capable of bearing arms is, from his twentieth to his fiftieth year, liable to service. The active army in 1900 was composed as follows:—

	Officers.	Men.
Infantry	1314	21,291
Cavalry	452	5,042
Artillery	179	1,982
Engineers	9	119
Other services	114	1,641
	2068	30,075

On war footing the numbers may be increased to 120,000 infantry, 20,000 cavalry, and 6000 artillery. The infantry are armed with the Mauser rifle, the cavalry with the Mauser carbine; the artillery are provided with Bange field-guns and Gruson mountain batteries.

Navy.—The Mexican navy in 1900 comprised 2 first-class gunboats (450 tons), 2 second-class gunboats (425 tons), a transport

ship, 2 despatch boats, a corvette, and a training-ship. The personnel of the navy consists of 90 officers and 500 men.

Agriculture.—It is estimated that Mexico contains about 3400 square miles of thick forests, 113,280 of woodland, and 299,280 of uncultivated land. The highlands of the central plateau can produce all known varieties of wheat, maize, beans, and root crops, as well as agave (maguey) and grapes, and they are also adapted to stock-raising. In the hot region rice, sugar-cane, tropical fruits, cacao, and rubber can be produced; and in the temperate region coffee grows abundantly, as do also all the products common to this zone in other countries. Notwithstanding this capability of the soil, agriculture is carried on to a very limited extent and by antiquated methods, due to scarcity of labourers and of means of communication, as well as to ignorance of agricultural matters. The Government endeavours to improve the conditions by disseminating useful knowledge and distributing seeds and plants, especially vines, olives, fruit trees, cork, oak, fodder plants, and flax, besides mulberry trees and silk-worms. It has also taken measures to extend irrigation. The quantities of the principal cereals produced in 1898 and 1900 were as follows:—

Crops.	1898.	1900.
Wheat, tons	235,360	331,500
Rice, "	20,710	20,360
Barley, bushels	12,977,220	10,203,580
Maize, "	107,905,320	89,354,360

The chief wheat-producing states are Chihuahua, Guanajuato, Puebla, and Sonora. A favourite crop in general cultivation in Mexico is beans (*frijol*), the total yield of which in 1899 amounted to 12,314,400 bushels. Of root crops the most usual is the sweet potato or *camote*, and, at a long interval, the common potato. The cultivation of the sugar-cane is carried on throughout the hot region and a great part of the temperate, its yield ranging from about 40 to 60 tons to the acre. Official returns give as follows the production of sugar and its by-products in 1898 and 1900:—

Products.	1898.	1900.
Sugar, tons	66,770	73,554
Brown sugar, "	71,650	65,689
Molasses, "	65,210	51,770
Rum, gallons	13,729,760	11,312,900

Coffee is widely cultivated both in hot and temperate regions, but chiefly in Vera Cruz. Cocoa is grown in Tabasco, vanilla in Vera Cruz, and tobacco most extensively in Tabasco. The yield of these products in 1900, with the values, was as follows:—

Product.	Quantity.	Value.
	lb.	£.
Coffee	46,393,870	604,850
Cocoa	4,341,374	170,980
Vanilla	32,798	47,267
Tobacco	20,555,830	243,910

The chief gums collected are chicle and caoutchouc, the former to the amount of 4,690,940 lb, valued at £143,270, and the latter to the amount of 434,630 lb, valued at £24,530 in 1900. Cotton has been cultivated from time immemorial. The staple of the Mexican cotton is longer than that of the United States, but not so soft and lustrous. The chief cotton-growing states are Durango and Coahuila. The total yield in 1898 amounted to 100,156,687 lb, in 1900 to 47,950,970, the value in the latter year being estimated at £614,877. One of the most important products is henequen (*Agave rigida*), also called Sisal grass or Sisal hemp. The production of this fibre in 1898 amounted to 66,235 tons, valued at £1,535,120; in 1900 to 85,860 tons, valued at £1,826,280. The production of ixtle (*Agave ixtle*), another fibrous plant, in 1899 amounted to 8305 tons, valued at £80,860. Many fruits are produced, and the official statistics annually state the production of 68 varieties. In the official list of the flora of the hot lands there are enumerated 233 distinct species of medicinal plants, 14 dyewoods, and 193 varieties of trees, among which are numerous valuable hardwoods.

Live Stock.—The raising of cattle has always been one of the most important industries. The states in the northern part are practically vast cattle ranges. The total consumption of meat in the republic in 1899 comprised 817,037 cattle, 807,375 sheep, 680,908 pigs, and 620,723 goats, the whole being valued at £4,597,365.

Mining.—The great mining region runs from the north-west to the south-east, following the direction of the Sierra Madre Cordillera from Sonora to the south of Oaxaca, a distance of 1600 miles. The richest mines have been discovered on the west slope of the Cordillera at an elevation of from 3000 to 8200 feet. The number of mineral districts is 1092. In 1901 the number of existing titles to mining properties amounted to 12,518, covering an area of 209,700 acres; of these 2666 were for gold and silver claims, 4328 for silver claims, 1922 for silver and lead, 1059 for gold. Besides gold, silver, lead, mercury, copper, iron, antimony,

tin, zinc, sulphur, &c., there are also deposits of precious stones, such as the opal, topaz, emerald, agate, amethyst, and garnet. The production of the principal metals was as follows, in quantity and value, in 1899:—

Metals.	Quantity.	Value.
Gold, oz.	263,830	£670,490
Silver, ,,	43,266,900	5,398,950
Copper, tons	26,962	1,465,930
Lead, ,,	62,550	405,120
Iron, ,,	3,239	28,230
Mercury, lb	273,090	26,970

The total value of the metallic output for the year was £8,479,774.

Industries and Manufactures.—Mexico has only manufactures of such articles as are required by the mass of the people. The principal article of manufacture is a coarse unbleached cotton cloth called *manta*, in the production of which over 26 million pounds of cotton are annually used, and more than 50,000 families directly or indirectly employed. In 1898–99 there were 125 mills with 491,443 spindles, 14,759 looms, employing 23,731 hands. The production of *manta* reached 10,239,799 pieces, and of yarn 4,171,290 lb. A considerable quantity of cotton yarn is used in the manufacture of shawls and scarfs (*rebozos*), knitted goods, &c. Mexican industry also produces woollen blankets (*zarapes*) and blankets of mixed cotton and wool. Silk-weaving is in its infancy, but is rapidly progressing. There are a few paper mills. Sugar mills and distilleries are numerous. In 1899–1900 there were 2065 distilleries producing 7,664,732 gallons of spirits from sugar, maguey, and grain. The tobacco industry is extensive, nearly every town having a cigarette factory, the quantity of tobacco manufactured in 1898–99 amounting to 12,202,690 lb. The flour mills cannot supply the local demand. Iron-foundries are numerous, but their work is mostly limited to the manufacture of small agricultural implements and ordinary marketable iron. The Government maintains a large arsenal and gun foundry in the city of Mexico. Hammocks and pottery are extensively manufactured, the former more especially in Yucatan. Cotton-seed oil mills are numerous, as are manufactories of chocolate, felt hats, rubber, &c.

Commerce.—The principal exports are precious metals, henequen, coffee, cattle, &c., while the principal imports are machinery, cotton and woollen textiles, iron and steel, wines and liquors, wood, paper and manufactures thereof, and textile fibres. The value of the imports and exports was as follows for the years named (the Mexican dollar being taken at two shillings and the gold dollar at four shillings):—

Years.	Imports.	Exports.
1895–1896	£8,450,780	£10,501,690
1898–1899	10,173,840	13,847,810
1900–1901	13,094,480	14,865,900

In 1900–1 the principal exports were as follows:—Silver, £4,319,400; silver coin, £1,638,480; silver ore, £1,274,200; gold, £859,200; henequen, £1,640,230; coffee, £688,980; timber, £239,020; cattle, £585,760; hides, &c., £497,400; tobacco, £150,940.

In the year 1900–1 the commerce was distributed as shown in the following table:—

Countries.	Imports from.	Exports to.
United States	£6,767,100	£11,722,900
Great Britain	2,217,100	1,203,310
France	1,383,900	282,430
Germany	1,476,600	501,850
Spain	596,200	118,770
Other countries	653,600	1,036,640

In 1900 the trade between Mexico and the United States, by railway overland, amounted to £2,102,860 imports and £3,938,360 exports; a total of £6,041,220.

Shipping.—In 1900 Mexico had a merchant marine of 17 steamers of in all 3961 tons net, and 50 sailing vessels aggregating 8445 tons. In the year 1900, including coasting trade, 8905 vessels of 6,670,429 tons entered the ports. The number of British vessels that entered was 803 of 1,241,231 tons, and of American, 1432 of 2,620,456 tons. The ports which have the largest share in the foreign sea-borne trade of Mexico are Vera Cruz and Tampico.

Railways.—The railways, though their construction began only about 1870, had in 1900 a total length of 9600 miles. In the populous region round the capital they form a complicated network extending across the country from the Gulf to the Pacific, while from the long trunk lines running from Mexico City to the frontier of the United States branches have been constructed for the development of the mining industries. The first railway concession, granted in 1857 and renewed and amended in 1867 and 1868, authorized the construction of a line from the capital to Vera Cruz, and in 1873 this line, called the Mexican railway, was opened for traffic. The main line is 264 miles in length, and there

are two branches, one to Puebla and another to Pachuca, of 29 and 28 miles respectively. The Interoceanic railway connects Vera Cruz, Jalapa, and Puebla with Mexico City, and then runs southwards to Jotutla and Amacuscac (1894), to be ultimately extended to Acapulco on the Pacific. The main line has a length of 463 miles, while its several branches have a length of 92 miles, the longest being the Matamoros branch of 42 miles. At Amacuscac the line joins the Mexico, Cuernavaca, and Pacific railway, which, with a length of about 500 miles, runs from the capital to Mexcala and ultimately reaches the Pacific at Sihuatanejo. Puebla and Oaxaca have been connected since 1892 by the Southern railway, 228 miles in length, which has been extended to Ejutla, about 35 miles to the south. The National Tehuantepec railway, constructed under a law of 1882, connects Coatzacoalcos on the Bay of Campeche with Salina Cruz on the Pacific, 192 miles distant. This system is connected by rail with Vera Cruz, and a line is being constructed from Cordoba on the Mexican railway, which will run to Santa Lucretia on the Tehuantepec railway. In Campeche and Yucatan there is a railway system of over 320 miles, connecting the ports of Campeche and Progreso with Merida, Valladolid, and other inland towns. The Mexican Central railway, running from Mexico City to Ciudad Juarez on the northern frontier, a distance of 1224 miles, was opened in 1884, and has now branches with an aggregate length of nearly 1000 miles. The branch from Irapuato to Guadalajara, opened in 1888, has been extended to Ameca and Etzatlan, and from Guadalajara a line runs to Colima, Cayutlan, and Manzanillo on the Pacific coast. From Aguascalientes a branch runs to Tampico on the Gulf of Mexico, where there is a harbour constructed for and owned by the railway company, the Government having granted subsidies. A railway from Tampico to Monterey, opened in 1891 and subsequently extended to Treviño, with a total length of 388 miles, had been acquired by a Belgium company, but was in 1902 transferred to the Mexican Central Railway Company. The Mexican National railway, completed in 1888, runs from Mexico City to New Laredo on the frontier of Texas, a distance of 839 miles, and is extended into Texas for about 160 miles. The branches in Mexico have a length of 320 miles. One branch runs westwards from Mexico City to Morelia and Uruapan, a distance of 120 miles, and the system includes suburban lines near the capital. The International railway from Purfirio Diaz, or Piedras Negras, on the Texan frontier, to Lerdo on the Central railway, 410 miles distant, was opened in 1888. It has since been extended 130 miles to Durango, whence the line is continued northwards for 130 miles to Cuanacevi. A branch of 71 miles connects Reata on the main line with Monterey, and thus with the Monterey and Tampico system. The International railway is worked in connexion with the Southern Pacific railway of the United States. The Sonora railway from Guaymas on the Gulf of California to Nogales on the frontier of Arizona, nearly 280 miles in length, has been leased to the Southern Pacific Railway Company, and is worked in connexion with their system. The Mexican Northern railway (for mineral traffic) runs from Escanlon, on the Central railway, to Sierra Mojada, 81 miles; the Coahuila and Pacific railway has 100 miles of line open; the Chihuahua and Pacific has 125 miles open; the Rio Grande, Sierra Madre, and Pacific has 156 miles open, and will be continued to Guerrero and the Pacific coast. In the earlier stages of railway enterprise liberal assistance was granted by Government to companies undertaking the construction and working of new lines, but later the subvention system was more sparingly employed, and in concessions it is usually provided that the lines shall revert to Government at the end of ninety-nine years. The first Mexican railway was, with a Government subvention, constructed by a British company, and British capital is still largely invested in Mexican railways, but the rapid development is mainly due to the enterprise and capital of United States financiers. The following table shows for the year 1899 the number of passengers and the weight of goods carried on the principal Mexican railways, with the gross revenues expressed in sterling, the Mexican dollar being taken at two shillings:—

Railways.	Passengers.	Tons.	Revenue.
Mexican	799,575	940,000	£475,490
District (Mexico City)	25,235,528	...	192,390
National	909,965	1,019,000	691,660
Interoceanic	1,184,360	620,000	385,310
Central	1,837,299	1,886,000	1,560,210
International	213,276	741,000	438,000
Monterey to Gulf	149,604	219,000	129,360
Northern	5,207	194,300	146,990

The development of the railways may be judged from these figures:—In 1890 there were 6037 miles of line; in 1894, 7070; in 1896, 7550; in 1898, 9044; in 1900, 9798. The lines in 1900 consisted of 8454 miles under federal concession, 283 miles of

urban railway, 163 miles of foreign line under state concession, 333 miles for private use, and 565 miles of light railway. In 1899, 36,122,930 passengers and 5,852,000 tons of goods were carried on the railways of federal concession, the gross proceeds amounting to \$4,637,740. At the end of 1896 the amount of £12,134,370 had been paid in subsidies.

Post Office.—In the year 1900-1 the Mexican postal system was served by 2082 post offices, of which 594 were principal offices and 488 agencies. The correspondence (including letters and post-cards) amounted to 148,086,513 pieces, of which 109,669,465 were in the internal service and 38,417,048 in the international. Postal receipts amounted to £213,560, and expenses to £263,850. In 1899, 23 steamship lines had contracts with the Government for carrying the mails; of these, 11 were Mexican, 5 American, 4 English, 1 Spanish, 1 French, and 1 German.

Telegraph.—The extension of the telegraph system is shown by the following figures:—In 1890, 31,300 miles; in 1894, 38,310; in 1896, 41,040; in 1900, 43,394. The total length in 1900 was made up as follows:—

	Miles.
Federal lines	28,702
State lines	5,305
Private enterprise lines	2,433
Railway lines	6,954
Total	43,394

In 1900-1 the Federal lines were served by 362 telegraph offices; the number of messages transmitted was 2,604,711. In addition to the telegraph lines there were, at the end of 1900, 22,770 miles of telephone line belonging to the states or to companies. The number of instruments working in the service of the public in 1900 was 8600.

Money and Credit.—There is a gold coinage, but practically no gold is in circulation. Within the republic there are three mints (Mexico, Zacatecas, and Culiacan); the mint at Guanajuato was closed on 30th June 1900. At these Mexican silver is coined into dollars, which are shipped to China and other Eastern countries. The nominal value of the money coined in the years specified (expressed in Mexican dollars) is given in the following table. In the total of each year the small amount of copper coinage is included.

Years.	Silver.	Gold.	Total.
1890-91	\$24,237,449	\$308,083	\$24,764,402
1891-92	25,526,717	291,940	25,975,351
1892-93	27,169,876	361,672	27,618,604
1893-94	30,185,591	553,978	30,739,569
1894-95	27,628,981	545,237	28,207,175
1895-96	22,634,788	565,786	23,237,099
1896-97	19,296,009	453,474	19,781,733
1897-98	21,427,057	459,219	21,917,876
1898-99	20,184,117	715,882	20,910,693
1899-1900	18,102,630	598,086	18,723,726

There are 24 banks, 19 being banks of issue; their paper is not a legal tender, but is covered by deposits of coin. The Government issues no paper money, and as a rule does not retain any specie in the treasury, the National Bank, which acts as a depository, paying all the warrants, &c. On 31st January 1902 the capital of all the banks amounted to \$82,300,000; notes in circulation, \$72,890,000; cash, \$55,975,000. The metric system of weights and measures has been compulsory since 16th September 1896.

The history of Mexico from its separation from Spain till the year 1884 exhibits an almost continuous conflict in which the empire of Maximilian is a mere episode. The struggles, which may at first sight seem to be merely between rival generals, are seen upon closer examination to be mainly (1) between the privileged classes, *i.e.*, the Church and (at times) the army, and the mass of the other civilized population; (2) between Centralists and Federalists, the former being on the whole identical with the army, the Church, and the supporters of despotism, while the latter on the whole represent the desire for republicanism and local self-government. Similar conflicts are exhibited, though less continuously, by most of the other Spanish-American states. On both sides in Mexico there was an element of honest doctrinaires; but rival military leaders exploited the struggles in their own interest, sometimes taking each side successively; and the instability was intensified by the extreme poverty of the peasantry, which made the soldiery reluctant to return to civil life, the absence of a regular middle class, and the concentration of wealth in a few hands, so that a revolutionary chief was generally sure both of money and of men. The period of instability ceased soon after the second election of Porfirio Diaz in 1884. Under his rule the Federal system continued in name, but it concealed in fact, with great benefit to the nation, a highly centralized administration, very intelligent, and on the whole both popular and successful—a modern form of rational despotism.

General characteristics.

The war of independence which began in 1810 was largely a movement of native-born Mexicans against Spaniards, and had almost resulted in the extinction of the separated forces, when a new turn was given to the course of events by news of the revolutionary movements in Spain. The Spanish king, Ferdinand VII., was seen to be ready to profess Liberal principles in order to secure his throne. The Mexican Clericals and Conservatives, fearing lest disendowment, toleration, and other changes should be forced on them from Spain, induced Agustin de Iturbide, who had already been conspicuous in the revolution, to take the field against Guerrero, the only revolutionary leader still in arms, in order to suppress Republicanism and set up an independent and non-Liberal monarchy. Iturbide eventually combined with Guerrero, and proclaimed the "Plan of Iguala," which laid down, as the bases of the new state, the maintenance of the Roman Catholic religion and the privileges of the clergy, the establishment of a limited monarchy, and equality of rights for Spaniards and native-born Mexicans. Iturbide sought the co-operation of the viceroy Apodaca, who, however, refused; but he was presently superseded by General O'Donojú, who, being unable to get beyond Vera Cruz, recognized the independence of Mexico. O'Donojú shortly afterwards died; the Spanish Government repudiated his act; and Spanish troops held the fortress of San Juan de Ulúa, off Vera Cruz, till 1827. A provisional Junta, nominated by Iturbide, issued a declaration of independence (October 1821), and nominated a regency of five, with Iturbide as its president. The first Mexican Congress met 24th February 1822. A section of it favoured a republic; another, monarchy under Iturbide; another, which was broken up by the refusal of Spain to recognize Mexican independence, monarchy under a Bourbon prince. A conflict now arose between the Republican majority and Iturbide, which was settled by a military pronunciamiento in his favour, and the Congress was intimidated into electing him emperor. He was crowned 21st July 1822. Fresh conflicts, however, soon broke out between him and the Congress, and Antonio Lopez de Santa Anna, captain-general of Vera Cruz, proclaimed a republic, promising to support the Plan of Iguala. He was defeated at Jalapa and driven to Vera Cruz; but the army deserted Iturbide, who was compelled to abdicate (19th April 1823). The Congress deported him to Italy, and granted him a pension. He returned almost immediately, on the pretext that Spain was intriguing against Mexican independence, and on landing was arrested and executed (1st July 1824).

War of independence, 1810.

General Iturbide becomes emperor, 1822-23.

The Congress had meanwhile undone much of his work, and had divided into Federalists and Centralists, the latter largely Monarchists and Freemasons. The Federalists were strong enough to secure the adoption of a constitution (4th October 1824)

modelled on the United States, with additional and incongruous clauses, notably one declaring the Catholic religion to be alone recognized. A source of abundant discord was opened by the provision that each state should contribute its quota to the Federal revenues. No proper statistical basis for estimating the quotas existed, and the device gave each state a plausible reason for attempting secession on occasion. Moreover, the capital and some territory round it was severed from the rest of the Republic as a "Federal district"—another grievance intensifying the antagonism of the state to the central power. The Freemasons had been largely instrumental in overthrowing Iturbide; they now divided into the Escoceses (lodges of the Scottish ritual), who were Monarchist and Centralist, and the Yorkinos, who took their ritual from New York, and their cue, it was alleged, from the American minister, Joel Poinsett. An attempt at revolt, headed by Nicolas Bravo, vice-president, the Grand Master of the Escoceses, was suppressed, but dissensions ensued in the Yorkino party between the followers of President Guerrero (a man largely of native blood, and the last of the revolutionary leaders) and of Gomez Pedraza, the war minister. A conflict broke out, the Guerreroists were victorious, and the pillage of foreign shops in Mexico city (1828), among them that of a French baker, gave a basis for the foreign claims which, ten years later, caused the "Pastry War" with France. Meanwhile, attacks on Spanish ships off Cuba by a Mexican squadron, commanded by an American, David Porter, had induced Spain to send an expedition to reconquer Mexico, which, however, was decisively checked at Tampico by Santa Anna. During the invasion Vice-President Antonio Bustamante declared against President Guerrero; the bulk of the army supported him. Guerrero was deposed, and his partisans in the south, continuing their resistance, were defeated at Chilpancingo (2nd January 1831); and Guerrero, retiring to Acapulco, was enticed on board an Italian merchant-ship, and treacherously seized, tried, and executed (January-February 1831). Next year, however, a revolt broke out against Bustamante, which was joined by Santa Anna, and eventually resulted in a pronunciamiento in favour of Gomez Pedraza. He, and his successor, Vice-President Gomez Farias (1833), assailed the exemption of the clergy and of military officers from the jurisdiction of the civil courts, and Santa Anna took advantage of the situation to assume the presidency. He eventually became dictator, dissolved Congress (31st May 1834) and the state legislatures, and substituted creatures of his own for the governors of the states and mayors of towns, then retiring into private life. A new Congress, having resolved itself into a constituent assembly, followed up this Centralist policy (30th December 1836) by framing a new constitution, the Siete Leyes or Seven Laws, which converted the states into departments, ruled by governors appointed by the central authority, and considerably reduced popular representation. Antonio Bustamante became the first president under it. The French claims set up by the pillage of foreign shops in Mexico had, however, remained unsatisfied, and in 1838 a French fleet blockaded the coast, bombarded the fortress of San Juan de Ulúa, off Vera Cruz, and occupied the town. The Mexican Government gave way, threatened by Federalist risings and secessions of states, which culminated in 1841. Santa Anna appeared, nominally as a mediator, and put forward a programme, the bases of Tacubaya (28th September 1841), abolishing all the Siete Leyes except the part relating to the judicial system, arranging for a new constituent assembly, and reserving for the president

President Guerrero, 1825-31.

(himself) full power of reorganizing the administration. The Centralist Government, after a vain attempt to defeat him by professing a more thorough Federalism, gave way to force, and Bustamante was allowed to leave the country. But the new Congress was too Federalist for Santa Anna, and he retired, leaving the reins to Nicolas Bravo, under whose auspices a new Centralist constitution was established (1843). This expressly retained the privileges of the clergy and army, and was in some respects more anti-Liberal than that of 1836. But new complications were now introduced by the question of Texas.

Santa Anna dictator, 1834.

Texas, a state of the Mexican Union, had been settled largely from the United States in consequence of a land grant given by the Spanish viceroy to Moses Austin in 1820, and had been estranged from Mexico partly by the abolition of slavery under a decree of President Guerrero, and partly by the monstrous Centralist constitution of 1836. It then seceded. Santa Anna attempted to reduce it, but was defeated and captured by Houston at the battle of San Jacinto, and compelled to sign a treaty recognizing Texan independence, which he disavowed on returning to Mexico, as extorted by compulsion. A state of war thus continued nominally between Mexico and its seceded member, whose independence was recognized by England, France, and the United States. The slaveholders in the United States favoured annexation of Texas, and pressed the

Bustamante president, 1837.

various claims due from Mexico to American citizens, partly perhaps with the ulterior aim of forcing war. Most of these claims were settled by a mixed commission, with the king of Prussia as umpire, in 1840-41, and a forced loan was raised to pay them in 1843, which greatly increased the internal difficulties of Mexico, and stimulated the revolt of Paredes against Santa Anna, who had returned to power in 1844. It resulted in Santa Anna's downfall, imprisonment at Perote, and eventual exile (December 1844 to January 1845), and the election of General José Joaquín Herrera as president. But Herrera was displaced in the last days of the year 1845 by a pronunciamiento in favour of Paredes, who undertook to uphold the national rights against the United States, and who was elected president on 3rd January 1846. Texas had meanwhile applied for admission into the American Union. The annexation, rejected in 1844 by the United States Senate, was sanctioned on 1st March 1845, and carried out on 22nd December 1845. The Mexican minister withdrew from Washington, and both sides made active preparations for war.

The United States forces were ordered by President Polk to advance to the Rio Grande in January 1846. They established a depôt at Point Isabel (behind the opening of Brazos Santiago), and erected a fort in Texan territory, commanding Matamoros, on the Mexican side of the Rio Grande. This provoked the Mexican forces into a defensive invasion of Texas, to cut the American communications with Point Isabel. They were, however, defeated at Palo Alto (8th May) and Resaca de la Palma (9th May). There was an outburst of warlike feeling in the United States (accompanied with emphatic opposition to war in the North), and an invasion of Mexico was planned by three routes—from Matamoros towards Monterey in New Leon, from San Antonio de Bexar to Chihuahua, and from Fort Leavenworth to New Mexico. Importance attaches chiefly to the movements of the first force under General Zachary Taylor. During the war preparations President Paredes, suspected of intriguing to overthrow the Republic, had to give place to his vice-president Bravo, who in his turn gave way before the military partisans of Santa Anna, who was hastily recalled from his exile at Havana to assume the presidency and the conduct of the war (August 1846). He was allowed by the American squadron blockading Vera Cruz to pass in without hindrance. Probably it was thought his presence would divide the Mexicans.

The preparations of the United States took some months. It was not till 5th September 1846 that General Zachary Taylor could leave his depôt at Camargo on the Rio Grande, and March on Monterey. It was taken by assault 23rd September; Santa Anna was defeated at Buena Vista (near Saltillo) on 27th February 1847, and forced back on San Luis Potosí. New Mexico was occupied without opposition; Chihuahua was occupied, but not held, owing to the difficulties in maintaining communications; and Upper California was seized in the autumn of 1846 by John C. Fremont, who had been exploring a route across the continent, and by the United States Pacific squadron, and made secure by the aid of the New Mexico expedition. But as Mexico still continued to fight, it was determined to reach the capital *via* Vera Cruz. That city was taken by General Scott after a siege (9th to 29th March 1847); and after winning the battle of Cerro Gordo (18th April), and a long delay at Puebla owing chiefly to illness among his troops and the need of reinforcements, Scott marched on Mexico city, stormed its defences against greatly superior forces, and effected an entrance after severe fighting on 13th September 1847. This virtually ended the war: Santa Anna was deprived of his command, and the treaty of Guadalupe Hidalgo, concluded 2nd February 1848, ceded to the United States Texas, New Mexico, and Upper California, in return for a payment of \$15,000,000 by the United States to Mexico, and the assumption of liability by it for the claims of its subjects which it had hitherto been pressing against Mexico. The object of this payment was doubtless to strengthen the United States' title to the conquered territory. It is generally admitted that Mexico was provoked into aggression in order that additional territory might be available for the extension of slavery.

The American forces were withdrawn in May and June 1848 after the ratification of the treaty by Mexico. Under the presidency of Herrar (1848-51) praiseworthy attempts were made to restore order and the public credit. An arrangement was effected with English holders of Mexican stock, on the basis of a considerable reduction of the capital (swollen by arrears of interest) and of the annual interest thenceforward, which latter was made a charge on the customs revenue. An attempt was made to carry out a consolidation of the internal debt, which failed owing to the total inadequacy of the funds allotted for interest; the army was reduced and reorganized, new muskets were purchased, and the northern frontier was defended against Indians and raiders by military colonies, formed partly of civilized Seminole Indians from the United States. But the financial situation was desperate;

War with United States, 1846-48.

Treaty of Peace.

Herrera president, 1848-51.

the federal revenue, mostly from customs—which were evaded by extensive smuggling—was not half the expenditure; and Indian revolts in Yucatan (1847-50) and in the Sierra Gorda had added to the strain. Arista succeeded Herrera as president (January 1851), but resigned (January 1853) through inability to cope with the financial and social disorder.

After a sort of interregnum (January-March 1853) Santa Anna was recalled (by a vote of the majority of the states under the Plan of Arroyozarco, 4th February 1853, the result of a pronunciamiento), and made dictator in the interests of federation. His measures, partly inspired by an able Conservative leader, Lucas Alaman, proved strongly Centralist: one is especially noteworthy, the establishment of the ministry of "fomento," or encouragement to public works, education, and intellectual and economic development, which is a conspicuous aid to Mexican welfare to-day. He also negotiated (at the end of 1853) the sale of the Mesilla valley (now Arizona) to the United States, but the purchase money was soon dissipated. On 16th December 1853 Santa Anna issued a decree making himself dictator for an indefinite period, with the title of serene highness. A Federalist revolution soon broke out,¹ and on 1st March 1854, at Ayutla in Guerrero, a section of the army under Colonel Villareal proclaimed the Plan of Ayutla, demanding Santa Anna's deposition and the establishment of a provisional Government to secure a new constitution. Among the leaders in the movement were Generals Alvarez and Comonfort, and it is said that Porfirio Diaz, subsequently president, then a young soldier, made his way to Benito Juarez, then in prison, and arranged with him the preliminaries of the revolt. It spread, and Santa Anna, after severe but futile attempts to quell it, left the country (August 1854).²

The provisional president who succeeded him, General Carrera, proving too Centralist, was replaced by Alvarez (24th September 1855), two of whose ministers are conspicuous in later history—Ignacio Comonfort, minister of war, and Benito Juarez, minister of finance. Juarez (b. 1806), one of the most remarkable men of the 19th century, was of unmixed Indian blood.

Benito Juarez. The son of a Zapotec peasant in a mountain village of Oaxaca city, he was employed as a lad by a bookbinder in Oaxaca city, and aided by him to study for the priesthood. He soon turned to the law, though for a time he was teacher of physics in a small local college; eventually went into politics, and did excellent work in 1847 as governor of his native state. Juarez almost immediately secured the enactment of a law (Ley Juarez, 23rd November 1855) subjecting the clergy and the army to the jurisdiction of the ordinary courts. "Benefit of clergy" was the curse of Mexico. Officers and soldiers could be tried only by courts-martial, the clergy (including numbers of persons in minor orders, who were practically laymen) only by ecclesiastical courts, and both sets of tribunals exercised civil as well as criminal jurisdiction, and were unduly favourable to their own order.³ The measure roused the Clericals to resistance. Alvarez gave place (8th December 1855) to his war minister Comonfort, who represented the less anti-Clerical Liberals. He had to suppress a Clerical rising in Puebla (March 1856), which was punished by a considerable confiscation of Church property; sanctioned a law releasing Church land from mortmain, by providing for its sale, for the benefit, however, of the ecclesiastical owners (called after its author Miguel Lerdo de Tejada, brother of the subsequent presidents), and a new draft constitution, largely modelled on that of the United States, and implicitly incompatible with the maintenance of special ecclesiastical privileges (5th February 1857). The clergy protested violently, and the Plan of Tacubaya (17th December 1857), which made Comonfort dictator, and provided for the construction of a new constitution under his auspices, was forced on and accepted by him. He was presently displaced by a thorough reactionary, General Zuloaga, and expelled from Mexico early in 1858; and for three years Mexico was a prey to civil war between two rival governments—the Republicans' at Vera Cruz under Juarez, who, as Chief Justice of the Supreme Court, succeeded Comonfort under the constitution in the presidential office; and the reactionaries' at the capital. The latter were at first presided over by Zuloaga, who, proving incompetent, was replaced at the end of 1858 by Pezuela, who early in 1859 gave place to Miguel Miramon, a young, able, and

unscrupulous soldier, who was shortly afterwards accepted as "constitutional" president by his party. The Juarists were defeated outside the city of Mexico twice, in October 1858 and on 11th April 1859. On the second occasion the whole body of **Miramón** officers, who had surrendered, were shot with Miramon's authority, if not by his express orders, together with several surgeons (including one Englishman, Dr Duval) and medical students who were tending the wounded of both armies, some as volunteers (the "martyrs of Tacubaya"). This atrocity caused great indignation in Mexico and abroad: the reactionists were divided; their financial straits were extreme, as the Juarists held all the chief ports. Juarez was recognized by the United States, and allowed to draw supplies of arms and volunteers thence; and on 12th July 1859 he published laws declaring ecclesiastical property confiscated, establishing civil marriage and registration, transferring the cemeteries to civil control, and, in short, disestablishing the Church. As opening up a source of revenue other than forced loans, the chief reliance of his opponents, these laws probably contributed largely to his eventual success. But his occupation of all the chief customs ports of the Republic, and the apparent hopelessness of any ending to the conflict, together with the frequent outrages of both parties on foreigners, afforded strong reasons for foreign intervention. Early in 1859 President Buchanan had recommended the step to Congress, which did not respond. On 12th December 1859 the M'Lean-Juarez treaty was concluded, which gave the United States a sort of disguised protectorate over Mexico, with certain rights of way for railroads over the Isthmus of Tehuantepec and between the Rio Grande and Pacific. The American Senate, however, did not ratify the treaty, and a motion for its reconsideration late in 1860 came to nothing, owing to the approach of the War of Secession.

The question of a joint intervention of Great Britain, France, Spain, and Prussia was mooted between those Powers in 1860. Early in 1859 the outrages on British subjects had caused the British minister to break off diplomatic relations. Forced contributions had been levied by both sides on goods or bullion, being European property, in transit to or from the coast, the reactionaries being the worst offenders; indeed, a seizure of British specie made by a Juarist, General Degollado, was repudiated by Juarez himself, and restitution was ordered; and there were numerous shocking cases of murder and robbery of Europeans. At last, on 17th November 1860, Miramon, under the plea of necessity, seized \$660,000 in specie which had been left under seal at the British Legation and was intended for the bondholders. On 22nd December 1860 his forces were routed by the Juarist general Ortega at Arroyozarco, and his Government was overthrown.

Overthrow of Miramon, 1860.

Juarez entered Mexico city on 11th January 1861. He soon found that his Government was held responsible to Europe for the excesses of its rival as well as its own. Miramon's Government had violated the British Legation; the Spanish minister, with the Papal legate and two representatives of South American states, were expelled from the country for undue interference on behalf of the reactionaries; the payments on the British loan were suspended in fact, and afterwards formally by Juarez's Congress in July 1861; and various outrages had been committed on the persons and property of Europeans for which no redress could be obtained. Most serious and unreasonable were the Jecker claims. Jecker, a Swiss banker settled in Mexico, had lent Miramon's Government, when almost at its last extremity (March 1860), \$750,000, receiving in payment 6 per cent. bonds for \$15,000,000.⁴ Juarez's Government declined to recognize the whole claim, but seems to have been ready to accept liability for the sum lent, with interest. Jecker, whose firm had meanwhile gone into liquidation, became a French citizen, and his claim furnished Napoleon III. with another reason for interference. A convention between Great Britain, France, and Spain for joint interference in Mexico was signed in London, 31st October 1861. A separate arrangement of the British claims was negotiated by Juarez, but rejected by the Mexican Congress, November 1861; and the assistance of the United States with a small loan was declined, Mexican territory being demanded as security. On 14th December Vera Cruz was occupied by Spanish troops under General Prim; the French fleet and troops arrived soon after, with instructions to seize and hold the Gulf ports and collect the customs for the three Powers till a settlement was effected; Great Britain sent ships, and landed only 700 marines. In view of the unhealthiness of Vera Cruz, the convention of Soledad was concluded with the Mexican Government, permitting the foreign troops to advance to Orizaba, and incidentally recognizing Mexican independence. But as the

European intervention, 1861.

¹ Two filibustering expeditions at this time—one by William Walker, afterwards notorious in Nicaragua, in Lower California (December 1853), the other by Count Raoussot de Boulbon and some French adventurers in Sonora, in Santa Anna's interest (July 1854)—added to the general disorder.

² Santa Anna tried to get back to politics in Mexico after Maximilian's fall, without success. He was banished with other exiles in 1874, and died in obscurity in 1876.

³ It is even stated that the "housekeepers" of the priests, when in debt for dress, &c., supplied to them, would claim "benefit of clergy" in order to escape more easily.

⁴ The operation was most ingeniously disguised as a conversion scheme, the old and practically valueless bonds being exchangeable at a vast discount, and along with cash, for the new bonds, which were assured of a sale by being made legal tender for one-fifth of any payment of customs duties.

French harboured leaders of the Mexican reactionaries, and showed a disposition to interfere in Mexican domestic politics, which lay beyond the terms of the joint convention, Great Britain and Spain withdrew their forces in March 1862. For the refugees in Paris had been taken up by the Empress Eugenie and the French Clericals, and had revived the old idea of a Mexican monarchy, which Napoleon adopted in the autumn of 1861. More troops were sent from France. Their advance was checked by Zaragoza and Porfirio Diaz in the battle of Cinco de Mayo, 5th May 1862; and in September of that year 30,000 more French troops arrived under General Forey. Wintering at Orizaba, they recommenced their advance, 17th February 1863, besieged and reduced Puebla, and entered Mexico city, 17th June. A provisional government of Mexicans was established, nominated directly or indirectly by Dubois de Saligny, the French plenipotentiary. It adopted monarchy, offered the crown to Maximilian of Austria, brother of the Emperor Francis Joseph, and should he refuse, left its disposal to Napoleon III.

Maximilian, after making some difficulty as to renouncing his right of succession to the throne of Austria, as was required of him, accepted the crown subject to the approval of the Mexican people, and reached Mexico city, 12th June 1864. Juarez meanwhile had set up his capital, first in San Luis Potosi, then in Chihuahua. The new empire was unstable from the first. Before Maximilian arrived the provisional government had refused to cancel the sales of confiscated Church lands as the Clericals demanded. When he came, a host of new difficulties arose. A new loan, nominally of about eight millions sterling, but yielding little more than four, owing to discount and commission, was raised in Europe, but no funds were really available for its service. Maximilian spent his resources too freely in mere luxury, and carried the elaborate etiquette of the Court of Vienna to Mexico. Favouring, as he did, toleration of Protestantism, and the supremacy of the Crown over the Church, he was too liberal for the Clericals who had set him up. As a foreigner he was unpopular, and the regiments of Austrians and Belgians which were to serve as the nucleus of his own army were more so. As an administrator he was enthusiastic, but futile: his reforms, excellent on paper, could not be carried out, for the trained bureaucracy necessary—nay, even the material for it—did not exist. For a time he nominally held sway over about two-thirds of the country,—roughly, from lat. 18° to 23°, thus excluding the extreme north and south. Oaxaca city, under Porfirio Diaz,¹ capitulated to Bazaine—who had superseded the too pro-Clerical Forey in October 1864—in February 1865, and by the autumn of that year the condition of the Juarists in the north seemed desperate. But the towns asked for permanent French garrisons, which were refused, as weakening their own power of self-defence. Instead, the country was traversed by flying columns, and the guerillas dealt with by a French service of "contre-guerilla," who fought with much the same savagery as their foes. Directly the French troops had passed, Republican bands sprang up, and the non-combatant Mexicans, to save themselves, could only profess neutrality. Yet on 3rd October 1865, Maximilian, misled by a false report that Juarez had left the country, issued a decree declaring the Juarist guerillas, who whenever captured were to be tried by court-martial and shot. Mexican generals on both sides had done as much. But Maximilian's decree prepared his own fate.

The American Civil War ended in the spring of 1865, and a strong popular feeling was at once manifested in favour of asserting the Monroe doctrine against Maximilian's Government. In the summer there were threatening movements of United States troops towards the Rio Grande; early in 1866 Napoleon III. announced to the French Chambers his intention of withdrawing his forces; in response to a note of Seward, the United States secretary of state, of 12th February 1866, he was induced to promise their return by three instalments at specific dates (November 1866, March and November 1867). Maximilian now turned for support to the Mexican Clericals; meditated abdication, but was dissuaded by his wife Charlotte ("the better man of the two," as he had once jestingly said), who went to intercede for him with the Emperor of the French. Finding him obdurate, she went on to appeal to the Pope; on her way, at Botzen, she went mad (end of September 1866).

Maximilian had meanwhile drawn nearer to the Clericals, and farther from the French, and, to protect French interests, Napoleon III. had decided to send out General Castelnau to supersede Bazaine, arrange for the withdrawal of the French forces in one body, and restore the Republic under Ortega, who had quarrelled with Juarez, and was therefore, of all Republicans, least unacceptable to the Clericals. But fearing the prospect,

they induced Maximilian, who had retired to Orizaba for his health, to remain. Father Fischer, a German-American by extraction, was specially influential here. A conference of eighteen representative Mexicans was summoned, and refused his offer to retire by ten votes to eight. He yielded on condition that a congress of all parties should be summoned to decide the fate of the empire. Hereupon he returned to the capital; the Juarist dominion extended rapidly; the French troops left (in one body) on 5th February 1867, ignoring and ignored by the Imperial Government, and shortly after Maximilian took command of the army at Queretaro. Here, with Miramon, he was besieged by the Juarists under Escobedo, and the garrison, when about to make a last attempt to break out and seek refuge in the fastnesses of the Sierra Gorda, was betrayed² by Colonel Lopez to the besiegers (15th May 1867). Maximilian, with the Mexican generals Miramon and Meija, was tried (fairly enough) by court-martial, and, refusing (or neglecting) to avail himself of various opportunities of escape, was convicted on charges which may be summarized as rebellion, murder, and brigandage, on 14th June, and executed, with Miramon and Meija, on 19th June 1867.

Meanwhile Porfirio Diaz had captured Puebla (2nd April) and besieged Mexico city, which fell 21st June. The Republican Government behaved with comparative leniency, though Juarez and Diaz were to some extent forced on by their followers, who rejected a general amnesty. The last anti-Juarist stronghold (Inayarit) submitted on 20th July 1867. A good deal of discontent was caused among the Republican rank and file, partly by the reduction of the army, and partly by a proposal to allow priests to vote, which came to nothing, and in the result Juarez's election in October to the presidency was opposed by Diaz, or rather Diaz's friends, but without success. But so soon as Juarez was elected, insurrections broke out in various states, and brigandage prevailed throughout the following year. There were unsuccessful insurrections also in 1869 (Clerical) and 1870 (Republican), but an amnesty, passed 13th October 1870, helped to restore peace; trouble again arose, however, at the 1871 election, at which the candidates were Juarez, Sebastian Lerdo de Tejada, and Diaz. Juarez's continued re-election was regarded as unconstitutional, and no party obtaining a clear majority, the matter was thrown into Congress, which elected him. Diaz's supporters refused to recognize him, and a revolution broke out, which went on sporadically till Juarez's death on 18th July 1872. Sebastian Lerdo de Tejada, as president of the Supreme Court, succeeded him, and amnestied the rebels, but made no further concessions. In the next year, however, laws were passed repeating in a stronger form the attacks of 1857 on the supremacy of the Church, and prohibiting the monastic orders or monastic life. The first day of 1873 was marked by the opening of the Vera Cruz and Mexico railway. For the next two years there were only local disturbances, chiefly in Yucatan, and an Indian rising in Michoacan. Protestant missions established themselves (with some opposition) in the country, and diplomatic relations were renewed with France and Spain (1874). But towards the close of Lerdo de Tejada's term as president he was suspected of aiming at a dictatorship, and Diaz made preparations for a rising, then retiring to Brownsville. At the beginning of 1875 the revolution broke out in Oaxaca with the Plan of Tuxtepec, which was adopted by Diaz, and proclaimed as the Plan of Palo Alto (22nd March). Diaz's attempt to raise the north, however, failed, and, trying to reach Vera Cruz by sea, he was recognized on the steamer, recaptured while attempting a four-mile swim ashore, concealed by the purser for some days, generally inside one of the saloon sofas, and helped to get ashore in disguise at Vera Cruz. Lerdo was declared re-elected, but was overthrown and forced into exile (January 1877), and Diaz, who had assumed the provisional presidency, was declared constitutional president on 2nd May 1877. A law forbidding the re-election of a president till four years had elapsed from his retirement from office, the outcome of the Republican opposition to Juarez and Lerdo, was passed in the autumn of that year (but so modified as to enable Diaz to be re-elected indefinitely in 1887 and 1892).

Diaz's first presidency (1877-80) was marked by some unsuccessful attempts at revolution, notably by Escobedo from Texas; by the resumption of diplomatic relations with Spain, Germany, Italy, and some South American states (1877), and France (1880); by some frontier difficulties with the United States, whose soldiery had occasionally followed brigands into Mexican territory, and with Guatemala, which revived a claim dropped since 1858 to a portion of the state of Chiapas; and by considerable internal

¹ Diaz refused parole, and was confined at Puebla for some months, but made his escape, and was soon in the field again.

² Lopez said he acted as Maximilian's agent, but his story was generally rejected. Yet see Mrs. Tweedie's *Mexico as I Saw It*, 1901.

progress, aided by a too liberal policy of subsidies to railways. The boundary questions were settled under President Gonzalez (1880-84); relations with Great Britain were renewed in 1883. The claims of the railways, however, necessitated retrenchment on official salaries, and the president's plan for conversion of the debt roused unexpected opposition in an ordinarily subservient Congress. It was attacked with great force and eloquence by the youngest member of the house, Señor Miron; Señor Guillermo Prieto, a noted poet and ex-minister, added the weight of his authority to the attack; the students demonstrated against the Bill in the streets; and finally it was rejected, on the ground that the expenses of conversion were too heavy and the burden on Mexico too great. At the end of 1884 Porfirio Diaz was again elected president, and was continually re-elected, the constitution being twice modified expressly to allow him to continue in office (1887, 1892).

The history of Mexico from 1884 to 1902 is almost void of political strife. President Diaz's policy was to keep down disorder with a strong hand; to enforce the law; to foster railway development and economic progress; to develop native manufactures by protective tariffs; to introduce new industries, e.g., the production of silk and wine, of coca and quinine; to promote forestry; to improve elementary and higher education—for all which purposes the Ministerio del Fomento is a potent engine; to encourage colonization; and, above all, to place the national credit on a sound basis. The first step in this process was a settlement of the British debt by direct arrangement with the bondholders, who were induced to exchange their outstanding bonds (at a discount of about 85 per cent.) for 6 per cent. bonds secured on one-fifth of the import and export duties and the product of certain direct taxes (1887-88). In 1890 the Spanish bondholders' claims were satisfactorily arranged also. In 1891 the tariff was made more protectionist. In 1893 the depreciation of silver, Mexico's currency and principal article of export, necessitated stringent retrenchment in the diplomatic service and reduction of official salaries; but the budget balanced for the first time during many years, the floating debt was converted, and a loan raised for the completion of the Tehuantepec railway. After 1896 there were substantial annual surpluses, which were spent in reducing taxation and in the extinction of debt. In 1895 the 6 per cent. external debt was converted into a 5 per cent. debt, the bonds of which were in 1902 at a premium; in 1896 the alcabalas or interstate customs and municipal octrois were abolished, and replaced in part by direct taxation and increased stamp duties.

Financial reorganization.

The institution by Diaz of the *guardias rurales*, a mounted gendarmerie composed of the class who in former days drifted into revolution and brigandage, was a potent means of maintaining order, and the extension of railways and telegraphs enabled the Government to cope at once with any disturbance. The old local revolutions practically disappeared. In 1886-87 there were some disturbances in Coahuila, New Leon, Sinaloa, and Tamaulipas; subsequently hardly anything was heard of such disorders except on the Texan frontier, where in 1890 Francisco Ruiz Sandoval and in 1891 Catarino Garza made incursions into Mexico with some support from Mexican ranch-owners in Texas and speculators who expected mining concessions in the event of a revolution. But the raiders, though they seem to have had some sympathizers in the Mexican army, were few, and in fact little more than brigands. Occasionally the Church gave trouble—the presence of foreign priests was complained of; attempts to evade the law prohibiting conventual life were detected and foiled (1891, 1894); and there were Indian risings, repressed sometimes with great severity, among the Maquis of Yucatan and the Yaquis of Sonora. Now and then the old passions break out: in September 1897 an absurd attempt to assassinate President Diaz was made by a countryman named Arroyo, who was secured, and early next morning lynched in the central police office, partly by members of the force, ten of whom, however, were sentenced to death for the crime. Discontent with Diaz's rule was confined to a small minority.¹

In foreign affairs the rule of Diaz was uneventful. There have been transient disputes with the United States (1886, 1888). In 1888-90 and 1894-95 a boundary dispute with Guatemala became serious, and Mexican wood-cutters were driven out of the disputed territory between the rivers Xicoz and Usnmacinto by Guatemalan officials, on the ground that an arbitration in progress being suspended, the territory was still Guatemalan. But Guatemala gave way at the threat of war (January 1895). In the difficulty between England and the United States over the Venezuelan boundary (December 1895) Mexico expressed strong adherence to the Monroe doctrine

in the abstract, and suggested that its maintenance should not be left wholly to the United States, but should be undertaken by all American Powers.

In brief, under President Diaz's rule the history of Mexico is mainly economic. In the six financial years 1893-94 to 1899-1900 inclusive the yield of the import duties increased by upwards of 80 per cent.; the revenue from stamps (an excellent index of the volume of business) over 60 per cent., though the duties were reduced; the postal revenue from 1895-96 to 1899-1900 rose 60 per cent.; the telegraph revenue over 75 per cent. The great drainage tunnel which is to take the waters of the valley of Mexico, hitherto most inadequately drained, out to the Pacific was completed in 1902; the Tehuantepec railway, likely to prove a formidable rival to any interoceanic canal, approached completion. Both tunnel and railway were the work of an English firm of contractors, Messrs S. Pearson and Sons. Great improvements have also been made in the harbours at Tampico and Vera Cruz. In 1891 elementary education was reorganized, and made compulsory, secular, and gratuitous. Great attention has been paid to higher education, and—at least in the hospitals—to modern sanitation and hygiene.

¹ Don Agustin Itrubide, grandson of the emperor, godson and (perhaps) at one time the destined heir of Maximilian, was turned out of the army and imprisoned in 1890 for abusing President Diaz.

in the abstract, and suggested that its maintenance should not be left wholly to the United States, but should be undertaken by all American Powers.

Authorities.—For English readers the standard work is H. BANCROFT, *History of the Pacific States*, vols. vii.-ix. (Mexico, 1804-67), with vols. x. xi. (Texas), and vol. xii. (New Mexico, &c.). (In Bancroft's collected works the vols. are numbered xi.-xvii.) Also his *Popular History of Mexico*. For the war with the United States see R. S. RIPLEY, *The War with Mexico* (New York, 1849); G. D. MANSFIELD, *The Mexican War* (New York, 1849); and WINFIELD SCOTT'S *Memoirs*. For Maximilian, the Blue-books on Mexican affairs contained in *Accounts and Papers* (presented to Parliament), vol. lxxv. 1862, and vol. lxxiv. 1863, are valuable; E. DE KÉRATRY, *La Créance Jecker; L'Empereur Maximilien, son Élévation et sa Chute* (translated into English by Venables); *La Contre-Guerilla Française au Mexique*, are specially noteworthy; Prince FELIX SALM-SALM'S *Diary* gives valuable information as to his decline and fall. ULICK RALPH BURKE'S *Life of Benito Juárez* (London, 1894) is of considerable value and interest. For the period since 1887 information in English must be sought chiefly in magazine articles: MATIAS ROMERO, "The Garza Raid and its Lessons," *North American Review*, September 1892; DON AGUSTIN ITRUBIDE, "Mexico under Diaz," *ibid.* June 1894; ROMERO, "The Philosophy of Mexican Revolutions," *ibid.* January 1896; and C. F. LUMMIS, "The Awakening of a Nation," *Harper's Magazine*, 1897, February, March, and April are valuable, as giving information (especially the last named) and points of view. VAN DYKE, "Politics in Mexico," *Harper's Magazine*, 1885, vol. lxxi., gives particulars of the opposition to Gonzalez's debt conversion scheme of 1884. President Diaz's message of November 1896, giving an account of his stewardship from 1884 to that year, has been translated into French (*Rapport du Général Porfirio Diaz . . . à ses Compatriotes sur les Actes de son Administration*, &c.), edited by AUGUSTE GÉNIN, Paris, 1897. The early constitutions of the Republic have been published (in Spanish) in three volumes; a study of that of 1857 by B. MOSES (of the University of California) is in the *Annals of the American Academy of Political Science*, II. i. 1891. Many books, chiefly American, have been written on Mexico of late years from a tourist's standpoint. Mrs ALEC TWEEDIE'S *Mexico as I Saw It* (London, 1901) contains valuable information personally obtained from good authorities in Mexico, and some interesting experiences of President Diaz.

(J. S. MA.)

Mexico, a state of the Republic of Mexico, bounded on the N. by the state of Hidalgo, on the E. by Puebla and Tlaxcala, on the S. and S.E. by Morelos, on the S. and S.W. by Guerrero, and on the W. by Michoacan, with an area of 9250 square miles. It is one of the most important agricultural and industrial states. The leading manufacturing industries are cotton and woollen goods, bricks, dairy products, wines, glass-ware, flour-mills, sugar, distilleries, potteries, &c. The state is divided into fifteen districts. The capital, Toluca (population, 23,150), 46 miles from Mexico City, is a handsome town, containing fine public buildings; also cotton mills, breweries, oil and flour mills, ice factories, &c. Amongst other towns in the state are Zumpango (9090), Lerma (7167), San José de Malacatepec (6551), Tenango del Valle (5465), Metepec (5189).

Mexico, a city of Missouri, U.S.A., capital of Audrain county, at the intersection of the Chicago and Alton and

the Wabash railways, north-east of the centre of the state, at an altitude of 831 feet. Its site is uneven and hilly, and the street plan irregular. It is the seat of Hardin College, a Baptist institution for women, founded in 1873, which in 1899 had 23 instructors and 252 students. Population (1890), 4789; (1900), 5099, of whom 111 were foreign-born and 948 were negroes.

Mexico City, capital of the Mexican Republic, situated in the centre of a high plain, 7460 feet above sea-level, 263 miles west of Vera Cruz by rail. It has undergone considerable improvement, and a very large increase of the suburbs has also taken place. The principal undertaking has been the great canal scheme for the drainage of the Mexican valley, completed in 1898 at a cost of \$18,000,000. Almost equally important has been the introduction of a complete sewage system on the best scientific principles, a special feature being the flushing of the main drains by fresh water supplied by a pumping engine. The streets are lighted by electricity, and there is an adequate system of tramcars, formerly drawn by mules, but now on many lines propelled by electricity. In 1898 all the various hospitals were merged in one structure, consisting of thirty-five buildings on the scientific plan of pavilions, the whole erected at a cost of \$800,000. A new prison has been erected, and also a fine new House of Congress. The industries have multiplied as well as increased. There are large cotton, linen, and paper factories, brick works, cork factories, soap works, machine factories, &c. There are many large foreign business houses—German, French, English, and Chinese—the Germans having almost a monopoly in the hardware trade. Population (1895), 329,774; (1900), 368,777.

Meyer, Julius Lothar (1830–1895), German chemist, was born on 19th August 1830, at Varel in Oldenburg. Determining to adopt the profession of his father, who was a physician, he went to study medicine first at Zürich University in 1851, and then, two years later, at Würzburg, where he had Virchow as his teacher in pathology. Even before he took his doctor's degree (1854), the influence of Ludwig, under whom he studied at Zürich, had decided him to devote his attention to physiological chemistry, and with that end in view he went, after his graduation, to Heidelberg, where Bunsen held the chair of chemistry. There he drifted still farther from medicine, and was so influenced by Kirchhoff's mathematical teaching that he took up the study of mathematical physics at Königsberg under F. E. Neumann. In 1859 he became *Privat-docent* in physics and chemistry at Breslau, where in the preceding year he had graduated as Ph.D. with a thesis on the action of carbon monoxide on the blood. In 1866 he accepted a post in the School of Forestry at Neustadt-Eberswalde, but soon moved to Karlsruhe Polytechnic. There he had an opportunity of utilizing his early medical training to great practical advantage, for during the Franco-German campaign the Polytechnic was used as a hospital, and he took an active part in the care of the wounded. Finally, in 1876, he became professor of chemistry at Tübingen, where he died on 11th April 1895. His name is best known for the share he had in the periodic classification of the elements. He noted, as did Newlands in England, that if they are arranged in the order of their atomic weights they fall into groups in which similar chemical and physical properties are repeated at periodic intervals; and in particular he showed that if the atomic weights are plotted as ordinates and the atomic volumes as abscissæ, the curve obtained presents a series of maxima and minima, the most electro-positive elements appearing at the peaks of the curve in the order of their atomic weights.

His book on *Die modernen Theorien der Chemie*, which was first published in Breslau in 1864 and has passed through many editions, contains a discussion of this and other relations between the atomic weights and the properties of the elements. In 1882 he received from the Royal Society, at the same time as Mendeléeff, the Davy medal in recognition of his work on the Periodic Law. A younger brother, O. E. Meyer, became professor of physics at Breslau in 1864.

Meyer, Victor (1848–1897), German chemist, was born at Berlin on 8th September 1848, and studied at Heidelberg University under Bunsen, Kopp, Kirchhoff, and Helmholtz. At the age of twenty he entered Baeyer's laboratory at Berlin, and began original work in organic chemistry, attacking among other problems that of the composition of camphor. In 1871, on Baeyer's recommendation, he was engaged by Fehling as his assistant at Stuttgart Polytechnic, but within a year he left to succeed Wislicenus at Zürich. There he remained for thirteen years, and gained for himself a high place among contemporary chemists. It was during this period that he devised his well-known method for determining vapour densities at high temperatures (see CHEMISTRY in these new volumes), and carried out his experiments on the dissociation of the halogens with great heat, though it is to be noted that he himself never went so far as definitely to assert the decomposition of chlorine. In 1882, on the death of Weith, he undertook to continue the latter's lectures at the University on benzene derivatives, and his preparations for this task led him to the discovery of thiophen. In 1885 he was chosen to succeed Hübner in Göttingen, where stereo-chemical questions especially engaged his attention; and in 1889, on the resignation of his old master, Bunsen, he was appointed to the chair of chemistry in Heidelberg. He died on 8th August 1897. In recognition of his brilliant experimental powers, and his numerous contributions to chemical science, he was awarded the Davy medal by the Royal Society in 1891.

Mézières, chief town of department Ardennes, France, 152 miles north-east of Paris, an important junction on railway from Paris to Namur. It is now a fortified place of the second class. The walls have been demolished, detached forts having been erected outside their circle. There is a monument in memory of those who fell during the war of 1870–71, when the town was captured by the Prussians; also, a statue of Bayard. The church, which suffered severely in 1870–71, has since been restored. Population (1891), 4675; (1901), 7884.

Mezőhegyes, a market town of Hungary, in the county of Csanád, 31½ miles by rail north-west of Arad, with 6000 inhabitants. In the district is a great horse-breeding establishment founded in 1785 in connexion with a model farm. The town has a sugar refinery, a steam mill, and seven distilleries.

Mezzotint. See ENGRAVING.

Mhow, town of Central India, with British military cantonment, within the native state of Indore, on the Malwa branch of the Rajputana railway between Khandwa and Rutlam, 13 miles south of Indore. Population (1881), 27,227; (1891), 31,773. It is the headquarters of a military division, with a strong force of all arms. There are two high schools, a Zoroastrian and a Canadiah mission, the Dorabji Pestonji dispensary, with an endowment of Rs.28,500, and a gaol. The number of police is 135, and the expenditure on public works in 1897–98 was Rs.61,220.

Miagao, a town on the southern coast of the province of Iloilo, island of Panay, Philippine Islands. It

has a cool and healthful climate. The neighbouring country is hilly and sterile, but produces sibucao in considerable quantities. The weaving of fabrics of abacá (*Musa textilis*) and pine-apple fibre is the most important local industry. The language is Panay-Visayan. Population, 22,000.

Miasskiy Zavod, gold-mining centre and town of Russia, in the Urals, government of Orenburg, district of Troitsk, 4 miles from Mias railway station. The average annual extraction of gold amounts to 17,280 oz. Population, 10,580.

Miautze. See **LOLOS.**

Michigan, one of the north central states of the American Union, lying in the valley of the Great Lakes. It is composed of two peninsulas, of which the northern, or as it is commonly called, the upper peninsula, is rich in minerals of various kinds; the southern, or lower peninsula, is adapted to agriculture.

Population.—In 1880 the population was 1,636,937; in 1890 it was 2,093,889. In 1880 the density per square mile was 27.80, and in 1900 it had risen to 41.1. In 1900 the total population had increased to 2,420,982. During the last twenty years of the 19th century the natural increase averaged 16.6 per cent. per year. The centre of population has been gradually moving northwards and westwards. In 1900, 541,653 inhabitants (22.4 per cent. of the population) were of foreign birth, and 22,419 (0.9 per cent. of the population) were coloured, including 15,816 negroes, 240 Chinese, 9 Japanese, and 6354 Indians. In 1894, 200,447 were natives of British America; 96,384 of Great Britain and Ireland; 143,057 were Germans; 36,370 were from the Scandinavian peninsula; 32,868 were from Holland. These nationalities constituted 89 per cent. of the foreign population. There are eighty-five organized counties in the state, and seventy-eight incorporated cities. Ten cities had more than 15,000 inhabitants in 1900: Detroit, 285,704; Grand Rapids, 87,565; Saginaw, 42,345; Bay City, 27,628; Jackson, 25,180; Kalamazoo, 24,404; Muskegon, 20,818; Port Huron, 19,158; Battle Creek, 18,563; Lansing, 16,485. Nine cities had between 10,000 and 15,000 inhabitants: Ann Arbor, 14,509; Manistee, 14,260; Ishpeming, 13,255; West Bay City, 13,119; Flint, 13,103; Menominee, 12,818; Alpena, 11,802; Sault Ste Marie, 10,538; Marquette, 10,058. The proportion of population of incorporated cities and villages to the total population of the state was 50.1 per cent. The so-called urban population, classing as such all persons in cities of 8000 inhabitants or more, amounted to 747,334, or 30.9 per cent. of the total population, as against 26.1 per cent. in 1890. The death-rate in 1900 was 13.9 for the entire state. For the rural districts and the cities of less than 8000 inhabitants it was 13.3; for the rest of the cities it was 15.3.

Education.—At an early date Michigan obtained from the general government two townships of land for the support of a university, and, like many other Western states, one section in each township in the state for the support of schools. The funds received from the sale of these lands are held by the state as trust funds on which interest is paid. The annual income accruing to the University of Michigan from this source is \$38,500. The school fund held by the state amounts to \$4,694,625, and the income distributed to the schools from this source amounted to \$319,430 in 1898. There are still over 190,000 acres of school land unsold; the university lands are almost entirely disposed of. The state holds a sum of \$625,790 as a trust fund for the Agricultural College, and \$66,128 as a normal school fund. In addition to these sums, the public schools received \$636,982 from state specific taxes on corporations in 1898. These sums, supplemented by district taxation, show an annual expenditure of \$7,867,640. In 1898 the ungraded school districts, numbering 6485, enrolled 208,751 pupils, while the graded school districts, 672 in number, enrolled 287,274. The total school attendance in 1898 was

541,490. In 1900 the number of persons of school age (5 to 20 years inclusive) was 790,275. The higher public institutions of learning are the University, which in 1900 had 3441 students, and 225 persons on the teaching staff; the State Normal College, with 979 students and 46 teachers; the Central Normal School, with 314 students and 14 teachers; the Agricultural College, with 528 students (1899) and 35 teachers; the Northern State Normal School at Marquette, with 90 students and 6 teachers; the College of Mines, with 122 students and 17 teachers. In 1894, 5.7 per cent. of all persons of both sexes over five years of age could not read or write. The illiterates twenty-one years of age and over were 2.7 per cent. of the population. In 1900, when the total male population twenty-one years of age and over numbered 719,478, 39,230 (of whom 26,823 were foreign-born) could not write.

Religion.—There were in 1894, 3936 church organizations holding property valued at \$20,775,156. The six largest denominations are the Methodists, with 1044 churches and \$4,263,835 worth of property; the Baptists, with 370 churches and \$1,977,910 worth of property; the Lutherans, with 364 churches and \$1,633,675 worth of property; the Roman Catholics, with 362 churches and \$4,539,386 worth of property; the Congregationalists, with 284 churches and \$1,701,900 worth of property; the Presbyterians, with 238 churches and \$2,318,850 worth of property.

Charitable and Reformatory Institutions.—The school for the deaf at Flint and the school for the blind at Lansing may be classed as educational as well as charitable institutions. In 1898 the former had 412 pupils and the latter 109. The state public school for dependent and neglected children is situated at Coldwater; in 1898 the pupils numbered 529. The state has established an industrial home for boys at Lansing, an industrial school for girls at Adrian, a home for the feeble-minded at Lapeer, and the Michigan Soldiers' Home at Grand Rapids. Public institutions for the improvement of criminals are the state prison at Jackson, the state house of correction and reformatory at Ionia, and the house of correction and prison at Marquette. There are asylums for the insane at Kalamazoo (1308 patients), Pontiac (1057 patients), Traverse City (1011 patients), Newberry (300 patients), and Ionia (245 patients).

Agricultural Products.—Wheat continues to be the most important agricultural product. The acres sown in 1898 were reported as 1,698,453, and the amount produced as 33,006,869 bushels. The yield in bushels of other principal cereals is: Indian corn, 37,259,938; oats, 27,529,558; clover seed, 86,373. In the same year 1,890,181 tons of hay were raised, and 22,355,520 bushels of potatoes. The number of acres in the apple orchards decreased slightly during the last quarter of the 19th century, but in 1898, 6,024,975 bushels were raised. The acreage of peach orchards has grown with slight fluctuation. In 1881 there were 12,908 acres of peach orchards; in 1891 there were 20,124 acres; in 1898 there were 50,148. Of peaches 413,418 bushels were sold in 1880, and in 1898, 1,872,147 bushels were grown. The raising of small fruit has also considerably developed since 1890.

Lumber.—The lumber industry has materially diminished because of the rapid consumption of the standing timber. It has been estimated that Michigan had originally at least 150 billion feet of white pine. In 1897 not more than 10 billion feet were standing, and this was probably a large estimate. The largest cut of lumber ever made in a single year was in 1888, when the production is believed to have exceeded 4,200,000,000 feet. Since that time the decrease has been very marked. The following figures, though not official, are trustworthy, and include the cut of white pine, hemlock, and hard wood:—

Year.	Lumber—feet.	Shingles.
1885 . . .	3,578,138,732 . . .	2,574,675,900
1890 . . .	4,085,767,849 . . .	2,469,878,750
1895 . . .	2,731,029,535 . . .	1,360,535,500
1899 . . .	2,328,575,135 . . .	1,444,578,000

The eastern portion of the southern peninsula has been nearly cleared of pine timber; along the Saginaw river in 1899 there were probably not more than about 225,000,000 feet of timber cut. In Muskegon, where in a single year the cut has reached 750,000,000 feet, there are now only two or three mills, with an output of not far from 70,000,000 feet. The upper peninsula still has a good deal of lumber, but it is rapidly disappearing. In 1888 the Menominee River Boom Company handled 513,703,492 feet; in 1898 only 291,229,121 feet.

Fisheries.—The state through the agency of a commission has done valuable work in propagating fish and in protecting the natural industry. There are four state hatcheries, from which in two years (1897, 1898) 202,722,350 fish were planted in the waters of the state. The catch of all kinds in 1897 amounted to 32,602,745 pounds, valued at \$709,831.

Minerals.—Michigan produces more iron ore than any other state. The high quality of the ore and the unusual shipping facilities make the iron industry exceedingly important. In 1898

and 1899 the output was very large, amounting in the former year to 7,380,319 tons, in the latter to 9,265,524. Copper-mining has greatly developed. The copper companies have distributed in dividends \$96,933,120 since the beginning. Of this sum \$6,900,000 was divided or declared for payment in the first half of 1899. For 1899 the production of refined copper was 146,950,333 pounds. The output is 28 per cent. of the total production in the United States. Montana is the only state producing a larger amount. The Calumet and Hecla mine now employs 5000 men, and in 1899 turned out 89,610,963 pounds of copper. Michigan retains its position as first in salt production in the United States. The number of barrels manufactured in 1898 was 4,171,916, valued at about \$2,000,000. Large manufactories of soda ash and allied products have been established near Detroit, obtaining brine from deep wells. The coal deposits have attracted attention. In addition to those near Jackson, new mines have been opened in the Saginaw valley. The output in 1899 was 624,708 tons, and there are indications of a great development. There are many large beds of pure marl fitted to make the finest quality of Portland cement, for the manufacture of which companies have been organized and factories built. The daily production of cement for 1900 was estimated at 500 barrels.

Manufactures.—In 1900 Michigan ranked tenth among the states of the Union in the value of its manufactured products. The general increase in manufacturing industries during the decade 1890-1900 is shown by the following table:—

	1890.	1900.	Per cent. of increase.
Number of establishments	12,127	16,807	38·6
Capital	\$262,412,240	\$284,097,133	8·3
Salaried officials, clerks, &c.	15,267 ¹	13,858	9·2 ²
Salaries	\$11,364,892 ¹	\$12,562,855	10·5
Wage-earners (average number)	148,674	162,355	9·2
Total wages	\$54,982,906	\$66,467,867	20·9
Miscellaneous expenses	\$18,348,381	\$25,495,423	39·0
Cost of materials used	\$154,521,918	\$199,559,905	29·1
Value of products	\$277,896,706	\$356,944,082	28·4

Statistics of twelve of the principal industries are as follows:—

Industry.	Number of Establishments.	Capital.	Value of Products.
Agricultural implements	59	\$8,932,344	\$6,339,508
Carriages and waggons	299	7,935,269	11,205,602
Cars, steam railway	4	6,693,209	9,920,780
Chemicals	51	7,503,853	5,364,724
Flouring and grist-mill products	765	7,933,587	23,593,991
Foundry and machine-shop products	364	19,595,771	20,615,864
Furniture	124	13,900,789	14,614,506
Iron and steel	10	3,859,050	5,902,058
Leather (tanned, curried, and finished)	27	5,214,042	6,015,590
Liquors, malt	77	6,235,484	5,296,825
Lumber and timber products	1705	67,379,698	54,290,520
Lumber, planing-mill products	235	8,571,453	12,469,532

The making of furniture is one of the greatest industries of the state; in Grand Rapids alone, which is the centre of the furniture business, \$7,494,607 worth of product was manufactured in 1900. One factory in 1899 consumed 2,800,000 feet of veneering and 4,800,000 feet of lumber. Half-yearly fairs are held in Grand Rapids, to which manufacturers in various parts of the country send exhibits, and which are attended by buyers from all over the world. In 1897 the legislature passed a law offering a bounty of one cent for every pound of sugar manufactured for the years 1897 and 1898. In 1900 there were nine large beet sugar factories, with an aggregate invested capital of \$4,013,743 and employing 437 persons. In the year ending 31st May 1900 the product of these factories amounted to 33,708,283 lb.

Railways.—There are 81 lines of railway, with a single track mileage of 10,497 miles. The capital stock is \$441,685,405. Their gross earnings in 1899 amounted to \$182,144,820, and the net earnings to \$55,827,574. During that year 48,195,594 passengers were carried and 102,456,846 tons of freight handled. The chief lines are the Michigan Central, the Chicago and Grand Trunk, the Lake Shore and Michigan Southern, and the Pere Marquette. Besides these there are many inter-urban electric lines.

Banks.—At the end of 1899 there were 187 state banks, 3 trust companies, and 80 national banks. The state banks and trust companies had as their paid-up capital \$12,262,100, with surplus and undivided earnings of \$5,090,321. The following table will show the depositors and the sums deposited on 31st December 1899:—

Banks.	Class of Deposit.	No. of Depositors.	Sums on Deposit.	Average to each Depositor.
187 State 80 National	{ Commercial Savings	77,857	\$ 36,772,566	\$ 472
		216,488	62,660,212	290
	Commercial	87,423	49,920,532	571
		381,768	149,353,310	391

Thus the total sum on deposit was nearly \$60 for every inhabitant in the state.

Finances.—The financial condition of the state has for many years been peculiarly good. On 30th June 1900 the treasury held a cash balance of \$2,501,557, while there was a total bonded indebtedness of only \$500,000, most of which was borrowed to defray the war expenses in 1898. There is also a trust-fund debt of \$6,273,144, on which interest is paid for the support of various state educational institutions. The aggregate value of property according to tax appraisal in 1896 was \$1,105,100,000. A re-equalization was made in 1901, in accordance with which the appraisal was \$1,578,100,000, because a great deal of personal property not before listed had been spread on the rolls. In 1896 the rate of taxation was 1·87 mills on the dollar; the next year it was 2·154 mills; in 1898 it was 1·95 mills, or a little less than one-fifth on 1 per cent. The proceeds from the direct taxes on real and personal property amounted in 1900 to \$3,725,835. In the same year \$1,438,946 were received from specific taxes on corporations.

History.—The Republican party has been successful in every election for governor except in 1882 and 1890, and since the formation of the party in 1854 has controlled the government, with the exception of four years. The constitution of 1850 still remains the fundamental law. The salaries paid under it to a number of the state officers were very small, and various amendments providing for an increase have usually been rejected. The salaries of the governor and the circuit judges have been increased. The Supreme Court is now composed of five justices, one of whom is chosen every two years. The state is divided in thirty-six judicial circuits, on some of which there are several judges.

Authorities.—COOLEY. *Michigan, A History of Governments (American Commonwealths)*. Boston, 1885.—See also the State Census Reports for 1884 and 1894, published at Lansing two years later in each case, the *Legislative Manuals, &c.*, for 1899-1900 (Lansing, 1899), and the reports of the various state officers for the year 1898 and 1899 (Lansing). (A. C. M.)

Michigan City, a city of Laporte county, Indiana, U.S.A., on Lake Michigan, near its southern end, and on three railways, the Chicago, Indianapolis, and Louisville, the Lake Erie and Western, and the Michigan Central, in the north-western part of the state, at an altitude of 600 feet. The city has a large trade by lake and rail, and varied manufactures. Population (1890), 10,776; (1900), 14,850, of whom 3662 were foreign-born and 197 were negroes.

Michigan, University of, the largest and most influential of the state universities of the United States, situated in Ann Arbor, Michigan, a city of 14,500 inhabitants, 40 miles from Detroit. It is the head of the state system of public instruction. Founded in 1837, it opened its doors in 1841, and graduated its first class in 1845. In 1900 its students numbered 3441. The enrolment in the different departments, including duplicates, was as follows: Literature, Science and the Arts, 1561; Engineering, 280; Medicine and Surgery, 500; Law, 882; School of Pharmacy, 76; Homœopathic Medical College, 70; College of Dental Surgery, 247. The teaching staff numbers 230 men. The five libraries, general, law, medical, dental, and homœopathic, contained, in 1899, 133,206 volumes. The laboratories are numerous and well-equipped. The higher degrees (Ph.D. and Sc.D.) are conferred only on examination. The university is co-educational, the ratio of men to women in all departments being about

¹ Includes proprietors and firm members, with their salaries.
² Decrease.

four to one, but in the literary department 5-6 to 4-4. The institution is supported partly by the income of its endowment fund, partly by fees, partly by appropriations from the state treasury. The total receipts for the fiscal year ending 30th June 1899 were \$530,000.

Michoacan de Ocampo, a state of Mexico, bounded on the N. by Guanajuato, on the N.E. by the states of Mexico and Queretaro, on the S.E. by the state of Guerrero, on the S.W. by that of Colima, on the W. by Jalisco, and on the S. by the Pacific. Its area is 22,881 square miles. The population in 1879 was 661,534, and in 1900 it was 935,849. It is mountainous, and has a wonderfully rich vegetation, and is also one of the richest mining sections of Mexico, gold, silver, copper, iron, cinabar, lead, sulphur, coal, marble, &c., being found in abundance. Foreign trade is carried on through the ports of Vera Cruz and Manzanillo and the frontier towns of Paso del Norte and Nuevo Laredo. The total trade amounts on an average to about \$25,000,000 a year. The Mexican National and the Mexican Central railways traverse the state. The manufacturing industries supply most of the local wants. The capital, Morelia, has 33,890 inhabitants. Amongst other towns are Zamora (10,373), Uruapan (9276), Angangueo (9115), La Piedad (8876), Sahuayo (8443), Puruandiro (7782), Patzcuaro (7082), Zatecuaro (6207), Tacambaro (5369).

Micronesia.—The three insular groups comprised under the expression MICRONESIA—*Carolinus*, *Marianas* or *Ladrones* and *Pelew* or *Palao Islands*—have been the scene of sweeping political changes, and of archaeological discoveries of exceptional interest. Since their discovery by Spanish navigators in the 16th and 17th centuries all the groups had been recognized as Spanish territory till the year 1885, when the Germans, after proclaiming the New Britain and Admiralty Archipelagos (see MELANESIA), took possession of Yap (Wap), one of the largest of the western Carolinas. Before that time Spain never had occupied this or any other member of the group, or even had any relations at all with the Archipelago, except indirectly through the natives of Guam, largest of the Marianas, by whom most of the local trade of the Archipelago is even still carried on. Nevertheless an energetic protest was at once raised, and on the question being referred for arbitration to the Papal Court, an award was given by Pope Leo XIII. in favour of the Spanish claim to all the Carolinas. Thereupon a treaty (December 1885) was concluded between Germany and Spain, in which the Spanish sovereignty over the Carolinas and Pelews was recognized, and the groups defined as lying between the limits of the equator and 11° N. and 133°-164° E. A first attempt was now made by Spain to bring about an effective occupation, and the Archipelagos were divided into two administrative districts—the Eastern Carolinas and the Western Carolinas with the Pelews. But the new system of government was resented by the natives, and a general revolt in the large island of Ponape had to be suppressed with much bloodshed in September 1890. This was the last act of sovereign authority exercised by Spain in these waters, and the Spanish flag disappeared from the Pacific insular world in June 1899, when the whole of Micronesia, with the solitary exception of the island of Guam, was sold to Germany. Micronesia comprises altogether about 680 islands and islets, stretching from west to east for over 2000 miles, but with a total population of perhaps less than 50,000. All the islands are of low coralline formation except the Pelews and Yap in the west, Ruk in the centre, and Ponape and Kusaie in the east, which are of a rugged hilly character, rising from about 800 to nearly 3000 feet in altitude. In the central and eastern parts of

Micronesia most of the foreign trade is in the hands of Japanese, American, and German shippers, who forward considerable quantities of copra, *bêche-de-mer* (sea-cucumber), vegetable ivory nuts, turtle-shell, and pearl-shell. In 1898 the copra exported from the Carolinas was stated to exceed 4,000,000 lb weight, of which nearly half was shipped at Yap.

The inhabitants of Yap on the western fringe of Micronesia are noted for possessing the most extraordinary currency, if it can be so called, in the whole world. Besides the ordinary shell money, there is a sort of stone coinage, consisting of huge calcite or limestone discs or wheels from 6 inches to 12 feet in diameter, and weighing up to nearly five tons. These are all quarried in the Pelew Islands, 200 miles to the south, and are now brought to Yap in European vessels. But some were in the island long before the arrival of the whites, and must consequently have been brought by native canoes or on rafts. The stones, which are rather tokens than money, do not circulate, but are piled up round about the chief's treasure-house, and appear to be regarded as public property, although it is hard to say what particular use they can serve. Mr Christian concludes that they are "more for show and ornament than for use." In Ponape and Kusaie, towards the eastern verge of the Carolina group, Herr Kubary, Mr F. J. Moss, and later Mr F. W. Christian, have made some remarkable discoveries amid the massive stone structures which were long known to exist in those islands, as well as in several other parts of the Pacific Ocean. None of the colossal remains hitherto described appear to have been erected by the present Melanesian or Polynesian peoples, while their wide diffusion, extending as far as Easter Island, within 400 miles of the New World, points to the occupation of the Pacific lands by a prehistoric race which had made some advance in general culture. The Funnafuti borings (1897) show almost beyond doubt that Polynesia is an area of comparatively recent subsidence. Hence the land connexions must have formerly been much easier and far more continuous than at present. The dolmen-builders of the New Stone Age are now known to have long occupied both Korea and Japan, from which advanced Asiatic lands they may have found little difficulty in spreading over the Polynesian world, just as in the extreme west they were able to range over Scandinavia, Great Britain, and Ireland. To Neolithic man, still perhaps represented by some of the more light-coloured and more regular-featured Polynesian groups, may therefore not unreasonably be attributed these astonishing remains, which assume so many different forms according to the nature of the locality, but seem generally so out of proportion with the present restricted areas on which they stand. With the gradual subsidence of these areas their culture would necessarily degenerate, although echoes of sublime theogonies and philosophies are still heard in the oral traditions and folklore of many Polynesian groups. In the islet of Lele, close to Kusaie, at the eastern extremity of Micronesia, the ruins present the appearance of a citadel with cyclopean ramparts built of large basaltic blocks. There are also numerous canals, and what look like artificial harbours constructed amid the shallow lagoons.

In Ponape the remains are of a somewhat similar character, but on a much larger scale, and with this difference, that while those of Lele all stand on the land, those of Ponape are built in the water. The whole island is strewn with natural basaltic prisms, some of great size; and of this material, brought by boats or rafts from a distance of 30 miles, and put together without any mortar, but sustained by their own weight, are built all the massive walls and other structures on the east side of the island. Ponape is of circular form, scarcely 16 miles in diameter, and with an area of 340 square miles; yet the walls of the main building near the entrance of Metalanim harbour form a massive quadrangle 200 feet on all sides, with inner courts, vault and raised platform with walls 20 to 40 feet high and from 8 to 18 feet thick. Some of the blocks are 25 feet long and 8 feet in circumference, and many of them weigh from 3 to 4 tons. There are also numerous canals from 30 to 100 feet wide, while a large number of islets, mainly artificial, covering an area of 9 square miles, have all been built up out of the shallow waters of the lagoon round about the entrance of the harbour, with high sea-walls composed of the same huge basaltic prisms. In some places the walls of this "Pacific Venice" are now submerged to some depth, as if the land had subsided since the construction of these extensive works. Elsewhere huge breakwaters had been constructed, the fragments of which may still be seen stretching away for a distance of from 2 to 3 miles. Most observers, such as Admiral Cyprian Bridge and Mr Le Hunte, agree that these structures could not possibly be the work of any of the present Polynesian peoples, and attribute them to a now extinct prehistoric race; that is, as here

Yap stone money.

The Ponape monuments.

suggested, the men of the New Stone Age from the Asiatic mainland.

(A. H. K.)

Microtomy is the term applied to the preparation of minute sections of organic tissue for the microscope. In 1875 the methods were yet in their infancy; their development has enabled observers to achieve the most exact study of minute anatomy, in the case of small objects, which without these methods could only be investigated by the unsatisfactory process of focussing with the microscope through the solid object. It is not necessary here to detail at length the well-known *wet method* of preparing sections. Briefly, the tissue is soaked in a solution of gum, or of gum and syrup, and after being frozen by ether spray, or by a mixture of ice and salt, is cut into sections either by the Rutherford, Cathcart, or some similar section-cutter, or by apparatus which can be fitted to the more modern types of microtome referred to below. This method, which is to-day used mainly by pathologists, has two main disadvantages: the prolonged action of watery fluids on the tissues, and the impossibility of getting ribbons, each section having to be picked up separately. The general processes of the *dry method* employed in zoological and botanical microtomy are, up to a certain point, practically identical with those used for the preservation of animals and their tissues for other branches of microscopic work. In the first place the tissues must be *killed*; in the second, they must be *fixed*, *i.e.*, the protoplasm must be set or coagulated as far as possible in the condition in which it appears in life; and in the third, they must be *hardened*, *i.e.*, in most cases dehydrated. Killing may be effected by asphyxiation or narcotization (nicotine, cocaine, chloral hydrate, &c.) in special cases, but is generally achieved by fixing reagents, of which corrosive sublimate and other chlorides, picric, acetic, osmic, and chromic acids, alone, or in combination, chromates, and strong alcohol, are the most usual. These serve to a great extent also as hardening agents, but alcohol, used after them, completes this process effectively, and when not too strong (70 per cent.) is the best storage fluid. The second set of processes relates to the *staining*, without which transparent sections are almost invisible. The stains are divisible into *general* stains, which dye the tissue practically uniformly and indifferently; and *selective* stains which have affinity for special tissues or cell elements. Of the latter group some fasten on nuclei, others only on the chromatin of the nuclei; some on connective tissues, others on muscle fibres, and so on. It is probable that the action of all these selective stains is produced by definite chemical combination with compounds originally present in, generated in, or introduced into the tissue selected. The most generally useful stains for ordinary work belong either to the *cochineal* series (borax-carmines, carmalum, &c.), or to the *logwood* series (hæmatoxylin, hæmalum, iron hæmatoxylin, &c.); in both of these great improvements have been introduced of late years by Dr Paul Mayer. The activity of these stains apparently depends upon the presence of alumina or of some similar base. For more special researches, such as cytology, neuro-pathology, neuro-histology, and so forth, greater dependence is placed on the *coal-tar* colours, the name of which is legion. Some of these, such as saffranin or gentian violet, are regressive stains; that is to say, the tissues are overstained uniformly, and the superfluous colouring matter washed out either by alcohol or by

weak hydrochloric acid from the unselected parts. Others, such as methyl green, are progressive—that is, the colour is brought up to the pitch required and the reaction promptly stopped. The coal-tar stains can be used singly, or in combinations of two or three. Some of the best, unfortunately, are not permanent. A third group of stains is furnished by such reagents as silver nitrate, gold chloride, and the like (impregnation stains), which can be made not only to stain, but also to deposit a fine metallic precipitate on certain structures. In the case of small and delicate objects, the staining is done in the mass before any further preparation for sections, but with larger animals, or large pieces of resistant tissue, the stain is applied to the sections only. The processes so far mentioned are applicable to many branches of microscopic work.

When preparing tissues for sections, the first step is complete dehydration, generally effected by bringing the object into absolute alcohol. It is then transferred to one of a group of reagents, which are miscible with absolute alcohol, but would form an emulsion with water, and are solvents of the embedding medium. The embedding mass in most general use is paraffin wax, melting at a temperature of 54° to 60° C., according to the character of the object and the thickness of section required. The object is transferred from absolute alcohol to benzol, chloroform, cedar oil, or similar fluid to the melted paraffin; the fluid diffuses and evaporates, leaving the tissues to be completely permeated by the paraffin. This process can be greatly hastened by the use of a partial vacuum. When impregnation is complete the paraffin is cooled rapidly so as to assume a homogeneous non-crystalline condition, and the tissue thus comes to form part of a block of soft but tenacious material, which protects it from damage by air or damp, and can be readily cut by a razor. The block is then trimmed to the form of a triangle or rectangle, and fixed by a clamp or by local melting in the holder of the microtome.

Numerous forms of excellent microtome have been evolved since 1885. Some of these have distinct advantages over others, but with microtomes, as with other tools, the success of the results depends very largely on the manipulator, for every one works best with his accustomed instrument. In one type of microtome the razor is attached at one end only to a heavy block, sliding backwards and forwards in a horizontal V-groove; the paraffin-block is fed to this either up a vertical guide (Schanze, Reichert, &c.), or up an inclined plane (Thoma-Jung). In another type the razor is firmly clamped at both ends to diminish vibration, and the paraffin block advances to it at the end of a long lever on trunnion bearings (Cambridge rocker), or up a vertical guide (Minot types).

In the selection of a microtome, apart from its steadiness, rigidity, accuracy of workmanship, and so forth, it must be borne in mind that, in general, simplicity of working parts means longer life, and that an elaborate "automatic" mechanism, by which a single movement is translated into several in different directions, not only complicates the machine, but robs the operator of those alterations of pace, rigidity, pressure, &c., which are often necessitated by the varying texture in different parts of the object cut. For general use by less skillful students in a laboratory, price, simplicity, and rapidity of work recommend the rocking microtome of the Cambridge Scientific Instrument Company, but it tends to fail at large or hard objects. For the all-round work of an investigator, its simplicity and finish have made Jung's sliding microtome with the Naples improvements deservedly popular for many years; it can be fitted with special apparatus for cutting celloidin and frozen objects, and it can be relied upon to cut any tissue, however difficult; but it cannot be worked as rapidly as some

others, nor produce long ribbons of large objects. For this latter purpose the Minot-Becker, Minot-Zimmermann, and Reinhold-Gilltay have been strongly recommended; these, however, are all of more complicated construction, with corresponding liability to uneven wear and damage; they are highly "automatic," leaving nothing but pace under control of the operator, and they are (particularly the last) expensive.

The sections, when cut by the microtome with the knife straight and the two sides of the rectangular paraffin block parallel to it, in most cases can be got off in a continuous ribbon, each sticking to its predecessor. This very desirable result generally can be insured by a coating of softer paraffin; but if the object be large, or brittle, or of varying texture, it is safer to cut the sections singly from a triangular block with an oblique knife. The sections or ribbon are often not quite flat, but rolled, creased, or compressed; they must be flattened before being attached to the slide. It is possible to carry out these two processes simultaneously by covering the carefully-cleaned slide with plenty of a very dilute solution of Mayer's glycerine and albumen, and laying the sections on the fluid and the slide on a hot-plate; as the water becomes warm the sections flatten out, and as it evaporates they settle down on the slide, and are held there by the albumen (many other methods are in use). The slide is then warmed to melt the paraffin, and plunged into benzol, or some similar fluid, which removes the paraffin; thence into absolute alcohol which dehydrates and coagulates the albumen. If the tissue has not been stained *en bloc*, the sections can now be stained on the slide. After staining they are finally dehydrated, rendered transparent by oil of cloves, and mounted in xylol-dammar or Canada balsam.

For ordinary work the paraffin method excels all others for rapidity, certainty, and cleanliness; but for large and hard objects, or crumbling tissues (such as ova with a large quantity of yolk), some manipulators prefer to embed in celloidin. By this method, after dehydration, the tissue is soaked in a mixture of absolute alcohol and ether; thence transferred either to increasingly strong solutions of celloidin in the same mixture or to a thin solution which is then boiled down till strong. The celloidin mass is then hardened, at first, if necessary, by drying, afterwards by a bath of chloroform or its vapour; it can then be cut in the microtome, either wet, or (if previously cleaned with cedar oil) dry like a paraffin block. The method is more tedious and more messy than the paraffin process; but amongst its advantages must be reckoned that little or no heat is required, and that the embedding mass is transparent, though it does not allow of such thin sections as paraffin.

The above accounts present an outline of the complex processes employed to-day, by which, on the one hand, sections $30\ \mu$ in thickness may be made through the entire human brain, and, on the other, organisms invisible to the naked eye may be cut into a long ribbon of consecutive sections $1\ \mu$ (one-thousandth of a millimetre) thick, every minutest fragment being retained in its proper place. The standard book on the subject is Bolles Lee's *Microtomist's Vade Mecum* (5th edition, 1900), but this should be used only to supplement direct practical training in a laboratory.

(G. H. FO.)

Middelburg, ancient capital of the Dutch province of Zeeland, in the middle of the island of Walcheren, 4 miles north by east of Flushing, on the Rozendaal-Flushing railway. There are steam tramway and steamboat service to Flushing, and canals to Veere and Arnemuiden. Flourishing agricultural markets, flour and margarine factories, and trade in wood indicate partial

revival of trade. In 1876 a large new dock was opened. The Zeeland society has increased its treasures with maps, plans, and drawings relating to Zeeland—*Zeelandia Illustrata*—and a complete collection of the fauna and flora of the province. Population (1882), 15,939; (1898), 18,635.

Middelburg (Transvaal). See TRANSVAAL.

Middleboro, a town of Plymouth county, Massachusetts, U.S.A., in the south-eastern part of the state, with an area of 73 square miles of rolling surface, interspersed with lakes and ponds. It contains several small villages, the largest of which bears the same name as the town. It is traversed by a branch of the New York, New Haven and Hartford railroad. Population (1890), 6065; (1900), 6885, of whom 920 were foreign-born.

Middlesbrough—often spelt MIDDLESBOROUGH, though never locally, the charter having been granted under the first name—a municipal, county (1888), and parliamentary borough, seaport, and market town of Yorkshire, England, on the Tees, 238 miles by rail north of London. Among modern erections are a music hall, co-operative stores, and extensions of the public baths. The high school was enlarged in 1892. The municipal buildings, costing about £130,000, were opened in 1889; thither has been removed the free library. There are 2 daily newspapers. In 1888 the artificial channel branching off from the river, by which the docks are reached, was deepened from 23 to 28 feet and widened from 80 to 200 feet, an extreme width of about 230 feet having been given at the mouth of the channel. The docks have also been enlarged to the extent of about 4 acres, and made accessible at all states of the tide for the largest vessels up to 8000 tons burden. There is nearly 1300 feet additional length of quay accommodation. Extensive tube works, wire mills, and oil works have become important. In 1891 there were 5460 persons employed in the iron and steel trade, and 1437 persons in the making of machinery. The imports of foreign and colonial merchandise in 1898 were valued at £1,081,693, against £773,485 in 1888. The exports of produce of the United Kingdom in 1898 were valued at £4,592,415, against £2,675,795 in 1888. The export of iron of all sorts in 1898 was valued at £2,887,067; of machinery and mill work, at £186,152; of cotton yarn, at £397,941; of cotton manufactures, at £382,940. In 1900 the total value of the exports was £6,318,282. In 1901 the output of pig-iron at the furnaces within the port amounted to 1,920,000 tons (annual average of 1896-1901, 2,190,250 tons); and in the same year 960,785 tons of pig-iron and 353,649 tons of manufactured iron and steel were exported. 99 vessels of 35,806 tons were registered in 1888, 67 of 39,594 tons in 1900. Vessels entering the port in 1888 numbered 3445 of 1,340,940 tons; clearances, 3619 of 1,380,279 tons. Entrances in 1900 numbered 3495 vessels of 1,843,165 tons; clearances, 3463 of 1,836,353 tons. Area of municipal and county borough, 2824 acres. Population (1881), 55,934; (1891), 75,532; (1901), 91,317.

Middlesex, an inland county in the south-east of England.

Area and Population.—The area of the ancient county as given in the census returns is 181,301 acres, or 283 square miles, with a population in 1881 of 2,920,486, in 1891 of 3,251,671, and in 1901 of 3,585,139, the number of persons per square mile being 12,068, and of acres to a person, .05. The area of the administrative county is 149,046 acres, with a population of 792,225 in 1901. 31,484 acres of the ancient county were transferred under

the provision of the Local Government Act, 1888, to the county of London, and 771 acres to Hertfordshire; and under the London Government Act, 1899, South Hornsey has been transferred to London. The area of the registration county is 178,754 acres, with a population in 1891 of 574,999, and in 1901 of 810,213. Within this area the increase of population between 1881 and 1891 was 50·93 per cent. The excess of births over deaths between 1881 and 1891 was 75,765.

The following table gives the number of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1899:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	2104	12,240	6,332	246	201
1890	3149	16,475	9,290	251	246
1899	5309	21,963	11,850	361	314

The following table shows the marriage-, birth-, and death-rates per thousand of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1889-96.	1899.
Marriage-rate	10·4	11·3	11·1	11·3	11·7	13·2
Birth-rate	32·1	32·9	33·0	29·5	28·4	127·3
Death-rate	18·8	17·0	16·5	16·6	14·7	14·7
Percentage of illegitimate births	3·6	3·7	3·5	3·0	3·1	3·1

Both the birth-rate and death-rate are below the average of all England. The number of Scots in the county in 1891 was 6066; of Irish, 5834; and of foreigners, 4409.

Administration.—The ancient county is divided into seven parliamentary divisions, and contains no parliamentary boroughs, excepting those now included in the county of London. The administrative county includes the following urban sanitary districts:—Acton (37,744), Brentford (15,171), Chiswick (29,809), Ealing (33,040), Edmonton (46,899), Enfield (42,738), Finchley (23,591), Friern Barnet (10,101), Greenford (819), Hampton (6812), Hampton Wick (2606), Hanwell (10,437), Harrow (10,220), Hendon (22,450), Heston and Isleworth (30,838), Hornsey (72,056), Kingsbury (757), Southall Norwood (13,200), Southgate (14,993), Staines (6686), Sunbury-on-Thames (4544), Teddington (14,029), Tottenham (102,519), Twickenham (20,991), Uxbridge (8585), Wealdstone (5852), Wembley (4568), Willesden (114,815), Wood Green (34,183). With the exception of the City of London, which has a separate police force, the county of Middlesex is wholly within the Metropolitan Police District and jurisdiction of the Central Criminal Court. The administrative county has one court of quarter sessions, and is divided into eight petty sessional divisions. The ancient county, which is almost entirely in the diocese of London and province of Canterbury, contains 122 ecclesiastical parishes and parts of eleven others, exclusive of those now in the county of London. Part of Stanwell parish is in the diocese of Oxford.

Education.—The number of elementary schools in the county on 31st August 1899 was 245, of which 84 were board and 161 were voluntary schools. The average attendance at board schools was 435,298, and at voluntary schools 177,124. The total school board receipts for the year ended 29th September 1898 were over £287,985. The income under the Agricultural Rates Act was over £1813. At Twickenham there is a training college for school-mistresses, and one at Spring Grove for masters. At Whitton, Kneller Hall is a college for military musicians. In 1899 there were twelve reformatory and industrial schools in the county.

Agriculture.—Nearly two-thirds of the area of the county is under cultivation, and of this about one-fourteenth is in permanent pasture. In 1899, 4316 acres were devoted to small-fruit cultivation, and 3656 were under wood. There is no heather land in the county. The following table gives the main divisions of the cultivated area at intervals from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	117,087	17,169	14,161	3236	81,470	1051
1890	112,847	12,811	12,755	2806	80,873	771
1899	102,198	9,469	10,875	2517	73,940	1081

The following table gives particulars regarding the principal live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	6183	25,859	16,790	32,267	10,962
1890	6240	20,878	14,100	21,358	11,667
1899	6279	16,742	9,096	18,717	13,271

Industries and Trade.—According to the annual report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 23,922, as compared with 20,744 in 1896. Textile factories only employed 27. In non-textile factories 20,497 persons were employed, as compared with 17,875 in 1896. Of this number 6143 were employed in the manufacture of machines, appliances, conveyances, or tools. Of the 3398 persons employed in workshops, 1894 were employed in the clothing industries. The chief industries besides these are brick- and tile-making, malting, distilling, and soap-making. The gunpowder mills known as the Houston Mills are extensive establishments.

London, 1864.—HARTING. *Birds of Middlesex*. London, 1866.—*Transactions of the London and Middlesex Archaeological Society*. London, from 1860. (H. B. W*.)

Middleton, a municipal borough (1886) and market town in the Middleton parliamentary division of Lancashire, England, 5 miles north of Manchester on the Lancashire and Yorkshire railway. There are chemical works and coal mines, but the staple industry is in cotton and silk. Population (1881), 19,750; (1901), 25,178.

Middletown, a city of Connecticut, U.S.A., capital of Middlesex county, on the west bank of the Connecticut river, 30 miles from its mouth, and on the New York, New Haven and Hartford railroad. It is well laid out, with broad, shaded streets, and has a good water-supply brought by gravity. Wesleyan University, which is situated here, had, in 1899, 35 professors and instructors, and was attended by 331 students, 75 of whom were women. Its property was valued at \$1,983,133, and its income was \$108,669. Population (1890), 9013; (1900), 9589, of whom 2316 were foreign-born and 127 were negroes.

Middletown, a city of Orange county, New York, U.S.A., on the Walkill river, in the south-eastern part of the state, at an altitude of 564 feet. It is on three railways, the Erie, the New York, Ontario and Western, and the New York, Susquehanna and Western. Population (1890), 11,977; (1900), 14,522, of whom 1700 were foreign-born and 480 were negroes.

Middletown, a city of Butler county, Ohio, U.S.A., on the Miami river, on the Miami and Erie Canal, and on the Cincinnati, Hamilton and Dayton, the Cincinnati Northern, the Cleveland, Cincinnati, Chicago and St Louis, and the Middletown and Cincinnati railways, in the south-western part of the state, at an altitude of 667 feet. It has varied manufactures, among which the making of paper is prominent. Population (1890), 7681; (1900), 9215, of whom 769 were foreign-born and 314 were negroes.

Middletown, a borough of Dauphin county, Pennsylvania, U.S.A., on the east bank of the Susquehanna river, 9 miles below Harrisburg, and on the Pennsylvania and the Philadelphia and Reading railways, towards the south-eastern part of the state, at an altitude of 546 feet. Its manufactures are largely of iron and steel. Population (1890), 5080; (1900), 5608, of whom 340 were foreign-born and 289 were negroes.

Midhat Pasha (1822–1884), Turkish statesman, the son of a civil judge, was born at Constantinople in 1822. His father, a declared partisan of reform, trained him for an administrative career, and at the age of twenty-two he was attached as secretary to Faik Effendi, whom he accompanied in Syria for three years. On his return to Constantinople Midhat was appointed Chief Director of Confidential Reports, and after a new financial mission in Syria was made second secretary of the Grand Council. His enemies, however, succeeded in ousting him from this post, and caused him to be entrusted with the apparently impossible task of settling the revolt and brigandage rampant in Rumelia. His measures were drastic and their success was startling, and the Government made him an official of the first rank and restored him to his place in the Grand Council. In similar vigorous fashion he restored order in Bulgaria in 1857. In 1860 he was made vizier and pasha, and entrusted with the government of Nisch, where his reforms were so beneficial that the Sultan charged him, in conjunction with Fuad Pasha and Ali Pasha, to prepare the scheme for adapting them to the empire which was afterwards known as the law of the vilâyets. After further administrative work in his province, he was ordered to organize the Council of State in 1866, and was then made governor of Baghdad, where his success was as decisive as at Nisch, but attended with much greater difficulties. In 1871 the anti-reform influence of the Grand Vizier, Mahmoud Nedim, seemed to Midhat a danger to the country, and in a personal interview he boldly stated his views to the Sultan, who was so struck with their force and entire disinterestedness that he appointed Midhat Grand Vizier in place of Mahmoud. Too independent, however, for the Court, Midhat remained in power only three months, and after a short governorship of Salonica he lived apart from affairs at Constantinople until 1875.

From this time forward, however, Midhat Pasha's career resolved itself into a series of strange and almost romantic adventures. While sympathizing with the ideas and aims of the "Young Turkey" party, he was anxious to restrain its impatience, but the Sultan's obduracy led to a coalition between the Grand Vizier, the War Minister, and Midhat Pasha, which deposed him in May 1876, and he was murdered in the following month. His nephew Murad V. was in turn deposed in the following August and replaced by his brother, Abdul Hamid II. Midhat Pasha now became Grand Vizier, reforms were freely promised, and the Ottoman Parliament was inaugurated with a great flourish. In the following February, however, Midhat was dismissed and banished for supposed complicity in the murder of Abdul Aziz. He then visited various European capitals, and remained for some time in London, where he carefully studied the procedure in the House of Commons. Again recalled in 1878, he was appointed governor of Syria, and in August 1888 exchanged offices with the governor of Smyrna. But in the following May the Sultan again ordered him to be arrested, and although he effected his escape and appealed to the Powers, he shortly afterwards saw fit to surrender, claiming a fair hearing. The trial accordingly took place in June, when Midhat and the others were sentenced to death. It was, however, generally regarded as a mockery, and on the intercession of the British Government the sentence was commuted to banishment. The remaining three years of his life were consequently spent in exile at Taif in Arabia, where he died, probably by violence, 8th May 1884. To great ability, wide sympathies, and undoubted patriotism he added absolute honesty, that rare quality in a vizier, for he left office as poor as when he entered it. (G. F. B.)

Midlothian. See EDINBURGHSHIRE.

Midnapore, a town and district of British India, in the Burdwan division of Bengal. The town is 68 miles west of Calcutta; it has a railway station. Population (1881), 31,491; (1891), 32,264. It is an important centre of trade, being the terminus of a navigable canal to Calcutta, and also the junction for the Sini branch of the Bengal-Nagpur railway. There are manufactures of brass and copper wire. It has an American mission, a municipal college, with 31 students in 1896–97, a collegiate high school, nine printing-presses, issuing one vernacular journal, and a public library, founded in 1852.

The district of MIDNAPORE has an area of 5186 square miles; population (1881), 2,515,565; (1891), 2,631,516; and (1901), 2,792,953, showing an increase of 5 per cent. between 1881 and 1891, and of 6·2 between 1891 and 1901; average density, 538 persons per square mile. Classified according to religion, Hindus in 1891 numbered 2,321,424; Mahomedans, 171,412; Christians, 1545, of whom 73 were Europeans; aborigines, 137,135. The land revenue and rates in 1897–98 were Rs.25,96,556; number of police, 861; number of boys at school (1896–97), 115,516, being 58·8 per cent. of the male population of school-going age, compared with 28 per cent. for the province generally; registered death-rate (1897), 28·3 per thousand. Both silk and indigo are decaying industries. There are 31 indigo factories, with an out-turn of 700 maunds, valued at Rs.1,00,000. The navigable canal irrigates 70,000 acres. The district is traversed by the Bengal-Nagpur railway towards Orissa, with a branch to Chota Nagpur. (J. S. CO.)

Mieres, an industrial and mining centre in the province of Oviedo, Spain, 12 miles south of Oviedo by rail, on the river Candal or Lena. It has a mining school, a sanctuary of the Virgin del Carmen, a fine parish church, a town hall, and the palaces of three distinguished families. There is an active trade in agricultural products and in ores. There are also important iron, coal, and copper mines in the neighbourhood; and 3 miles to the north some thriving works which employ 2000 hands and turn out 40,000 tons of iron annually. The population in 1897 was 17,144.

Migration.—Under this title will be considered movements of men with intention of changing their residence or domicile. Such migration may be either external—that is, from one country to another, including emigration from mother country to colony; or it may be internal—that is, within the limits of a single country. Under external migration is comprised emigration and immigration, denoting simply direction from and to. The emigrants are at the same time the immigrants; that is, the material of the movement is the same, but the effect upon the country giving up and the country receiving the migrant requires separate treatment. Hence it is proper to separate emigration from immigration. Temporary migration, or travel for purposes of business, enterprise, or pleasure, will be considered only incidentally, and because in some cases it is difficult to distinguish between such movements and permanent migration.

Migration in general may be described as a natural function of social development. It has taken place at all times and in the greatest variety of circumstances. It has been tribal, national, class, and individual. Its causes have been political, economic, religious, or mere love of adventure. Its causes and results are fundamental for the study of ethnology (formation and mixture of races), of political and social history (formation of states and survival of institutions), and of political economy (mobility of labour and utilization of productive forces). Under the form of conquest it makes the grand epochs in history (*e.g.*, the fall of the Roman Empire); under the form of colonization it has transformed the world (*e.g.*, the settlement of America); under free initiative it is the most powerful factor in social adjustment (*e.g.*, the

growth of urban population). It must suffice here to indicate the character of the principal movements in the past, and then describe certain aspects of modern migration. The early movements may be grouped as follows:—

(a) Prehistoric migrations. Among savage and nomadic nations the whole tribe often moves into new territory, either occupying it for the first time or exterminating or driving out the indigenous inhabitants. We have only vague knowledge of these early movements, laboriously gleaned from archæology, anthropology, and philology. The cause has been commonly said to be the pressure of population on the food-supply. A more probable explanation is the love of booty and the desire of the stronger to take possession of the lands of the weaker. (b) Greek and Roman colonization. Both of these ancient civilizations extended their influence through migration of individual families and the planting of colonies. The motive seems to have been primarily commercial—that is, the love of gain. It may have been partly a sort of “swarming” process, caused by pressure of population at home. In some cases it had a political motive, as the planting of military colonies or providing new homes for the proletariat. The consequences were of course momentous. (c) The German Conquest. Beginning about the 5th century, the Roman Empire was overthrown by German tribes from the north of the river Danube and east of the river Rhine. This *Völkerwanderung*, as it is called by German historians, again transformed the face of Europe, resulting in the establishment of independent kingdoms and a great mixture of races and institutions. It was coincident with the building-out of the fœdal system. The conquered in many cases could be left as serfs and tillers of the soil, while the conquerors seized the higher positions of administration and power. (d) The later Middle Ages saw many minor migratory movements, such as those accompanying the Crusades, the pushing of German colonization among the Slavs, and the introduction of Flemish weavers into England. The religious reformation caused a considerable amount of expatriation, culminating in the expulsion of the Huguenots from France. (e) The Period of Discovery and Colonization. This opened up a new era for migration. The first expeditions were for adventure and booty, especially the discovery of gold and silver. Then came the establishment of commercial posts or factories for the purposes of trade. Finally came colonization proper—that is, the settlement of new countries by Europeans intending to remain there permanently, but still retaining their connexion with the mother country. This meant the opening up of the world to commerce and the extension of European civilization to vast areas formerly peopled by savages or half-civilized peoples. It meant a great outlet for the spirit of enterprise and adventure, relief from over-population, an enormous increase in wealth and power, and a struggle for supremacy among the nations of Europe. Colonization and colonial policy excited immense attention in Europe; and this extended even into the 19th century (*e.g.*, Wakefield’s plans for colonization, and the various colonization societies of modern times). The colonial policy proper was broken down by the revolt of the North American colonies from Great Britain, and later of Mexico and Central and South America from Spain. (f) The movement of population, however, has continued under the form of emigration. This movement is characterized firstly by its magnitude; secondly, by the fact that the emigrant changes his political allegiance, for by far the greater part of modern emigration is to independent countries, and even where it is to colonies, the colonies are largely self-governing and self-regarding; and thirdly, it is a movement of individuals seeking their own good, without State direction or aid. This is 19th-

century emigration, differing from all preceding forms and having an importance of its own.

Statistics of Emigration.—The direction of the modern movement is from Europe to America, Australia, and South Africa, as shown in the following table:—

Emigration from Certain States of Europe, 1890–99.¹

Year.	Italy.	France.	Belgium.	Holland.	Spain. ²	Portugal.	Austria-Hungary.	Switzerland.	Germany.
1890	115,595	20,560	2976	3526	37,025	28,945	74,002	6693	97,103

1899	2,799	87,400	16,072	42,890	146,362	

Since 1820 over twenty million persons have emigrated from Europe to countries beyond the sea. The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table of emigration from Great Britain and Ireland. Down to 1853 the figures include all emigrants from British ports; after 1853 emigrants of British and Irish origin only.

Emigration from Great Britain and Ireland, 1815–99.

<i>All Emigrants.</i>					
	To British North America.	To United States.	To Australia.	To other Places.	Total.

1891–99 9	163,533	1,042,707	112,759	249,566	1,573,565
1853–99 (47 years) . . .	902,149	5,782,254	1,421,535	589,593	8,695,531

The general direction of emigration from Europe is shown in the following table:—

¹ Compiled by the Italian Bureau of Statistics, with additions from the *Statesman’s Year-Book* for 1901. The figures relate only to the emigrants of each nationality emigrating from their own country to countries outside of Europe.

² Exclusive of emigrants to Spanish colonies.

³ Russian emigrants from German ports.

⁴ Of these, 77,409 went to the Cape of Good Hope and Natal.

⁵ Of these, 145,380 went to the Cape of Good Hope and Natal.

Statistics of Immigration.—The statistics of the United States are the most important and the most complete. The statistics since 1820 are shown in the following table:—

Immigration into the United States, 1820-1900.

Decade ending 30th June	Aggregate Arrivals.	Annual Average.
1830	143,439	14,343
1840	599,125	59,912
1850	1,713,251	171,325
1860	2,598,214	259,821
1870	2,314,824	231,482
1880	2,812,191	281,219
1890	5,246,613	524,661
1900	3,844,422	384,442
Total	19,272,079	

Prior to 1820 there was no official record of immigration, but it is estimated that the total number of immigrants from the close of the Revolutionary War was 250,000. During the decade from 1820 to 1830 the movement was very moderate. From 1830 to 1840 it steadily increased, but never reached 100,000 per annum. In 1846 came the Irish potato famine, and an enormous emigration began, followed by a very large German emigration from similar causes. The Civil War in the United States interrupted the movement, but it was speedily resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880-90, and declined after the commercial crisis of 1893. Later there were signs of another increase (448,572 in 1900).

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin of immigrants coming to the United States, 1871-95) is shown in the following table:—

Nationality of Immigrants to the United States.

	25 Years 1871-95.	Per cent. of Total Immigration.
Anglo-Saxons, Celts, and Welshmen—		
England and Wales	1,334,817	12·9
Scotland	286,807	2·8
Total	1,621,624	15·7

Total	986,676	9·5
Swiss—Switzerland	135,736	1·3
Greeks—Greece	7,325	
Turks—Turkey	3,411	
Europe, not specified	294	
Total Europe	9,197,014	88·9
North America	776,071	7·5
All other countries	366,454	3·6
Grand Total	10,339,539	100·0

A very important transformation has taken place in the proportionate number coming from different countries during the last half of the 19th century. At first the Irish and Germans were most prominent. Of later years the Italians, Czechs, Hungarians, and Russians were numerously represented.

The following table shows the relative number of different nationalities represented in the immigration to the United States:—

Country.	1861-70.	1871-80.	1881-90.	1891-95.
	Per cent.	Per cent.	Per cent.	Per cent.
Great Britain	24·5	16·4	12·5	9·3
Ireland	18·8	15·5	12·5	19·6
Germany	34·0	25·5	27·7	19·1
Austria-Hungary	·3	2·6	6·7	12·4
Norway and Sweden	4·7	7·5	10·8	9·3
Russia and Poland	·2	1·9	5·1	10·4
Italy	·5	2·0	5·9	12·8

Sex and Age.—Of all the immigrants (1871-95), 61·25 per cent. were males and 38·75 per cent. were females. This proportion differed somewhat among different nationalities, as shown in the following table:—

Proportion of Females among Immigrants, 1871-95.

	Per cent.		Per cent.
England and Wales	39·0	Denmark	38·0
Scotland	39·2	Norway	38·3
Ireland	49·5	Sweden	39·5
Austria-Hungary	35·4	Bohemia	47·3
Germany	42·4	Hungary	27·7
Netherlands	39·6	Poland	33·5
Belgium	34·9	Rumania	45·6
France	36·6	Russia	37·8
Italy	21·9	Switzerland	36·3
Portugal	23·4	British N. America	40·1

The emigrants were in the most vigorous period of life, few children and few old people, as shown in the following table:—

Ages of Immigrants to the United States, 1881-90.

Country of Origin.	Under 15.		From 15 to 40.		Over 40 years.	
	Number.	Per cent.	Number.	Per cent.	Number.	Per cent.
Germany	386,984	26·6	904,002	62·2	162,084	11·2
Ireland	92,308	14·1	515,089	78·6	48,085	7·3
England	151,315	23·5	420,308	65·2	73,062	11·3
Sweden and Norway	104,254	18·3	414,609	73·0	49,499	8·7
Italy	47,008	15·3	212,475	69·2	41,771	15·5
Russia (including Poland).	65,427	24·7	174,754	65·9	24,907	9·4
Austria	50,027	22·1	149,909	66·3	28,109	11·6
Scotland	36,192	24·2	97,819	65·2	15,858	10·6
Hungary	18,750	14·7	95,635	74·9	13,261	10·4

Occupation.—The immigrants are for the most part unskilled labourers. The statistics for the United States show the following figures for the ten years 1881-90:—

Occupation of Immigrants to the United States.

	Males.	Females.	Total.
Professional . . .	25,257	1,749	27,006
Skilled	514,552	25,859	540,411
Miscellaneous . . .	1,833,325	245,810	2,079,135
Not stated	73,327	42,830	116,157
Without occupation	759,450	1,724,454	2,483,904
Total	3,205,911	2,040,702	5,246,613

Those "without occupation" are mostly women and children. The "miscellaneous" are day labourers. It is probable that about 20 per cent. of the adult males are "skilled."

Immigration to other Countries.—In no other country is immigration so important as in the United States. The statistics are very imperfect. The main figures have already been given in the table of emigration. Australia has an annual immigration of about 250,000, mostly of British origin. This is offset by a very heavy emigration, which sometimes exceeds the immigration in certain of the states. The immigration to Canada for the year 1891 was put down as 82,165, but a portion of this consists of immigrants passing through to the United States. Brazil has had a large immigration (in 1895 equal to 169,524, but in 1898 only 53,822). The Argentine is credited with an immigration in 1899 of 111,083, and Uruguay with an immigration in 1895 of 9185. In all the South American immigration the countries principally represented are those of southern Europe, especially Italy. The majority of the immigrants are adult males and farm labourers.

Balance of Emigration and Immigration.—Even in the case of emigration from Europe to countries beyond the seas there is some return movement. Emigrants who have been successful in business return in order to end their days in the old country. Those who have not succeeded return in order to be cared for by friends and relatives, or simply from home-sickness. Thus, for Great Britain and Ireland, while the emigration of persons of British and Irish origin was, in 1899, 146,362, the immigration of persons of the same category was 100,246, leaving a net emigration of only 46,116. In the United States statistics we cannot distinguish in the outgoing passenger movement emigrants from other persons. But if for a period of ten years we take the total inward passenger movement and subtract from it the total outward passenger movement, we ought to have the net immigration. By this method we arrive at the conclusion that while the gross immigration during the ten years 1881-90 was 5,246,613, the net immigration was only

4,417,337, showing an outward movement of 829,276, or about 15·8 per cent. of the total number of immigrants.

Temporary Emigration.—In many European countries there is not only emigration beyond seas, but a very considerable movement to neighbouring countries in search of work, and generally with the intention of returning. Thus, in Italy the "permanent" emigration (*i.e.*, to countries beyond seas) numbered, in 1894, 101,206; the "temporary" emigration to neighbouring countries amounted to 124,139. This temporary emigration is strongest in the spring, and consists principally of adult males (agriculturists, farm and day labourers, bricklayers and masons) in search of work. It resembles somewhat the movement of Irish labourers into Great Britain at harvest time.

Effects of Emigration.—There are two views with regard to emigration: one unfavourable, viz., that it is a drain on population, reducing its economic strength and disturbing social and political relations; the second looking upon it as a relief from over-population and a congested labour market. As a matter of fact, emigration has not succeeded in diminishing the population of Europe, which, on the contrary, doubled during the 19th century. The one great exception is Ireland, where population has been reduced from 8,175,124 in 1841 to 4,531,051 in 1899. From 1851 to 1899 the total emigration from Ireland was 3,796,131, or 68·6 per cent. of the average population. Emigration, by carrying off the young men and women, has also reduced the Irish marriage- and birth-rates, which are the lowest in Europe. But hitherto the countries of strongest emigration (England, Germany, &c.) have shown practically undiminished birth- and marriage-rates and a steady growth in population.

The intensity of emigration is measured not by the absolute number of emigrants, but by the number of emigrants to the total population. Its effect is shown by comparing the number of emigrants with the excess of births over deaths per 1000 of the population. This is shown in the following table (1892):—

	Excess of Births over Deaths per 1000 Inhabitants.	Emigrants per 1000 Inhabitants.
Great Britain and Ireland	10·54	5·51
England and Wales	11·50	4·56
Scotland	12·17	5·74
Ireland	3·04	11·39
Germany	11·6	2·23
Switzerland	8·7	2·64
Sweden	9·1	6·87
Norway	11·9	8·53
Denmark	10·1	4·76
Italy	10·1	3·53
France	0·5	0·14

It will be observed that, with the exception of Ireland, wherever there is a heavy emigration, there is at the same time a considerable excess of births over deaths, *i.e.*, natural increase more than makes up for the loss by emigration. Even taking Great Britain and Ireland together, the loss by emigration per annum has not been very large, as is shown by the following table:—

Annual Emigration per 1000 of the Average Population of Great Britain and Ireland.

1853-55	8·4	1881-90	7·1
1856-60	4·3	1891-95	5·1
1861-70	5·2	1896	4·1
1871-80	5·1	1897	3·7

Even in particular districts where emigration is heavy, the loss is made up by births. For instance, in 1891 the emigration from the provinces of West Prussia and Posen was extraordinarily heavy—10·9 and 10·4 per mille respectively—but the excess of births over deaths was 19·6 per mille. Emigration may give temporary relief to con-

gested districts, but it is not in itself a remedy for so-called over-population.

It is difficult to analyse closely the economic effect of emigration, because so much depends upon the character of the emigrants and the condition of the labour market. The following considerations have been urged at different times:—Although emigration does not diminish population, yet, as the emigrants are in the most productive period of life (15 to 45), the country of emigration loses adults and replaces them with children. It thereby loses the cost of rearing that number of people to adult age, and is left with a disproportionate number of children and old people. The age distribution of the population of Ireland lends some support to this view. In the same vein it is urged that voluntary emigration takes away the cream of the working-classes. It is the man of energy, of some means, of ambition, who takes the chances of success in the new country, leaving the poor, the indolent, the weak, and crippled at home. It is maintained that such emigration institutes a process of selection which is unfavourable to the home country.

On the other side, it is said that the men who are doing well at home are the ones least likely to emigrate, because they have least to gain. Modern means of transportation have made the voyage so cheap that almost any one is able to go. It is therefore the restless, the unsuccessful, or at least those not fitted for the strenuous competition of the older countries, who are tempted to go. Emigration affords a natural outlet for the superfluous labour force of a country. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where they become producers of food and raw material for the home country, and at the same time customers for her manufactured products. Emigration is therefore an economic gain, both directly and indirectly. It is evident from these arguments that no general answer can be given to the question. In some cases it may be an evil; in most, when conducted under normal conditions, it would seem to offer little danger.

The same remark would hold true in regard to the social and political effects of emigration. In some cases, by taking away the strong, self-reliant, and energetic, it may result in the deterioration of the home population. In other cases it allows restless spirits who have failed at home to try again elsewhere. Often in cases of political revolution the members of the defeated party have sought refuge elsewhere, as after the revolutionary movements of 1848. In case of conquest the conquered nationality takes to emigration on an extensive scale, as after the absorption of Alsace-Lorraine by Germany in 1871. The movement may be aided either by the State or by private associations. Of such character have been the *State-aided* emigration from Ireland, and the *assisted* emigration of paupers, criminals, and other persons, in the effort to relieve a congested population, or simply from the desire to get rid of undesirable members of the community. Such efforts fail if the new countries are unwilling to admit these persons. Finally, we have the expulsion of the Jews from Russia as an example of the effort of a community to get rid of an element which has made itself obnoxious to the local sentiment.

Effects of Immigration.—The effects of emigration are negative in character; those of immigration are positive. (a) On population: Immigration, of course, is a direct addition to the population of new countries, and greatly accelerates the growth by natural increase, especially as the immigrants are in the most productive ages of manhood and womanhood. In the United States, for instance, out of a population of 76,303,387 (in 1900), there were

26,147,407 persons who were either foreign-born or who had one or both parents foreign-born. This does not mean that the population would have been twenty-six millions less if it had not been for immigration; for the rate of natural increase among the native-born might have maintained itself. Nevertheless, immigration has probably stimulated the growth of population. (b) Economic effects: The economic gain of immigration to new countries is evident. It adds directly to their available labour force, that is, to the number of adults engaged in the work of producing wealth.

According to the United States census of 1890, out of 22,735,661 persons engaged in gainful occupations, 5,104,757, or 22·5 per cent., were of foreign birth. If we add to these the native whites of foreign parentage (3,542,408) we have 8,647,165 persons of foreign extraction, or 38 per cent. of the total labour force. The foreign whites alone constituted 14·5 per cent. of the total number of persons engaged in agriculture, fisheries, and mining; 12·1 per cent. of those in professional services; 31·5 per cent. in domestic and personal services; 21·4 per cent. in trade and transportation; and 31·4 per cent. of those engaged in manufacturing and mechanical industries. In addition to these, the native whites of foreign parentage constituted, in agriculture, &c., 8·8 per cent.; in professional service, 16·3 per cent.; in domestic service, 14·2 per cent.; in trade and transportation, 22·1 per cent.; in manufacturing, 24·4 per cent. of all those engaged in those occupations. The labour force of the United States is thus made up very largely of immigrants and the children of immigrants.

Attempts have sometimes been made to put a money value on the economic gain by immigration. The amount of money brought by the immigrants is not large, and is probably more than offset by the money sent back by immigrants for the support of families and friends at home or to aid them in following. The valuable element is the able-bodied immigrant himself as a factor of production. It is said, for instance, that an adult slave used to be valued at from \$800 to \$1000, so that every adult immigrant may be looked upon as worth that sum to the country. Or, it has been said that an adult immigrant represents what it would cost to bring up a child from infancy to the age say of 15. This has been estimated by Ernst Engel as amounting to \$550 for a German child. The most scientific procedure, however, is to calculate the probable earnings of the immigrant during the rest of his lifetime, and deduct therefrom his expenses of living. The remainder represents his net earnings which he will contribute to the well-being of the new country. Farr reckoned this to be, in the case of unskilled English emigrants, about £175. Multiplying the total number of adult immigrants by any one of these figures, we get the annual value of immigration. Such attempts to put a precise money value on immigration are futile. They neglect the question of quality and of opportunity. The immigrant is worth what it has cost to bring him up only if he is able-bodied, honest, and willing to work. If he is diseased, crippled, dishonest, or indolent, he may be a direct loss to the community instead of a gain. So, too, the immigrant is worth his future net earnings to the community only if there is a demand for his labour.

Social and Political Effects of Immigration.—The influx of millions of persons of different nationality, often of a foreign language and generally of the lower classes, would seem to be a danger to the homogeneity of a community. The United States, for instance, has felt some inconvenience from the constant addition of foreigners to its electorate and its population. The foreign-born are more numerously represented among the criminal, defective, and dependent classes than their numerical strength would

justify. They also tend to segregate more or less, especially in large cities. Nevertheless, the process of assimilation goes on with great rapidity. Inter-marriage with the native-born occurs to a considerable extent. The influence of the physical environment leads to the adoption of the same mode of life. The most powerful influences, however, seem to be social. These are common school education and the adoption of one language (English); participation in political life, which is granted to all adult males after five years' residence; and the general influence of social standards embodied in laws, institutions, and customs already established. Doubtless immigration of the last fifty years of the 19th century has had a modifying effect on American life; but on the whole the power of a modern civilized community working through individual freedom to assimilate elements not differing from it too radically has been displayed to a remarkable degree.

Restriction of Immigration.—New countries have sought to escape certain evils of indiscriminate immigration. These evils were as follows:—(a) The immigration of criminals, paupers, persons diseased in mind or body, and persons unable to support themselves. By the Acts of 1882 and 1893 such persons were refused admission to the United States, and, when rejected, the steamship companies that brought them were compelled to take them back. The number rejected in 1899 was 3057. No law of international comity is violated by the refusal to receive these unfortunates. They should be taken care of at home. (b) Immigration sometimes increases the competition in the labour market, and thus lowers wages. One case is particularly aggravating, viz., when employers import foreign labourers in order to take the place of their men who are on strike. In 1885 the United States passed what is called the Contract Labour Law, forbidding the landing of any person who is under contract to perform labour in the United States. It is very difficult to discover such cases, and in 1899 only 741 persons were rejected on that account. (c) The immigration of men of alien race who refuse to assimilate with the natives is said sometimes to be a danger to the country. This at least is the excuse for the entire exclusion of Chinese labourers from the United States since 1882 (provisions made more severe in 1888 and 1892).

Internal Migration.—In modern times there is constant movement of population within national lines, from section to section, and especially from rural districts to the cities. No record is kept of this, and we can trace it only through the census statistics of birthplace. In the United States, for instance, it was shown in 1890 that more than 21·5 per cent. of the native-born inhabitants were living in a state other than that in which they were born. Still further, it appears that about one-half of the native-born inhabitants had moved out of the county in which they were born. In 1890 there were 1,233,629 natives of the state of New York living in other states. The movement is principally westwards in direction and along parallels of latitude. For instance, New York has made large contributions to the population of Ohio, Michigan, Illinois, Wisconsin, Iowa, and so on. Virginia has contributed largely to the population of West Virginia, Kentucky, Ohio, Indiana, Illinois, and Missouri. In Europe there is a similar movement; but it is difficult to make comparisons, because of the differences in the administrative areas. In England in 1891, 71·6 per cent. of the population were residing in their native county; in Prussia, 69·7 per cent. in the *kreis*; in France, 81·7 per cent. in the department; in Austria, 80·2 per cent. in the *bezirk*; in Switzerland, 82·1 per cent. in the canton where they were born (Weber, *Growth of Cities*, p. 249). The most important phase of internal migration is the movement from the rural districts to the cities. The statistical results are shown in the

following table extracted from the admirable work of Weber just quoted:—

Percentage of Population living in Towns of 10,000 and over at Three Periods.

	About 1800 or 1801.	About 1850 or 1851.	About 1890 or 1891.
England and Wales	21·3	39·5	61·7
Scotland	17·0	32·2	50·0
Australia (7 colonies)	41·4
Belgium	13·5	20·8	34·8
Netherlands	29·5	29·0	31·3
Prussia (1816)	7·3	10·6	30·0
United States	3·8	12·0	27·6
France	9·5	14·4	25·9
Denmark	10·9	9·6	23·6
Italy	20·6
Ireland	7·8	10·1	18·0
Norway	3·3	5·3	16·7
Switzerland (1822)	4·3	7·3	16·5
Austria	4·4	5·8	15·8
Hungary	5·4	9·1	16·1
Sweden	3·9	4·7	13·7
Portugal	12·7	12·9	12·7
Russia	3·7	5·3	9·3

Everywhere the city population is increasing faster than the rural. In the United States the rate of increase per decade was as follows:—

Year.	United States.	In Towns of 8000 and over.	Rural Districts.
	Per cent.	Per cent.	Per cent.
1790-1800	35·1	60	34
1800-1810	36·4	69	35
1810-1820	33·0	33	33
1820-1830	33·6	82	31
1830-1840	32·7	68	30
1840-1850	35·9	99	30
1850-1860	35·6	75	30
1860-1870	22·6	59	15
1870-1880	30·1	40	27
1880-1890	24·9	61	15
1890-1900	20·8	37	14

In England and Wales the rural population is actually decreasing, while the urban is increasing, as shown in the following table:—

Decennial Rate of Increase or Decrease.

Year.	Urban. Per cent.	Rural. Per cent.
1851-61	+21·9	+1·88
1861-71	+28·1	-5·86
1871-81	+25·6	-3·84
1881-91	+18·5	-2·76

In 271 out of 632 registration districts of England and Wales there was an absolute decrease of population from 1881 to 1891. The same phenomenon is seen in France. According to the census of 1891, not less than 55 out of the 87 departments had decreased in population; and out of the 32 that had increased, 7 showed a decrease in their rural parts when the large towns were deducted. In Germany the towns of 10,000 and over show a much more rapid increase than the rural districts; and the same fact is generally true of the other countries of Europe. This more rapid increase of population in cities is due only in part to migration from the country. Until the 19th century deaths generally exceeded births in cities, so that if it had not been for constant immigration the cities would not only not have grown, but would have decreased in population. Cities grow more rapidly now than formerly, because the excess of deaths over births has been turned into an excess of births over deaths. Thereby the cities are becoming less dependent upon immigration for increase of population than formerly, but the migration still goes on. The causes of migration from country to city are mainly economic. In early stages

of culture men are scattered over the country, or at most gathered together in hamlets and villages. Each of these is self-sufficing, having its own artisans and handicraftsmen, and producing what it needs. With the beginning of exchange, commercial centres spring up, situated on navigable streams and especially at points where land and water journey are broken. With the growth of manufactures, industrial centres spring up where the division of labour can be fully provided for. In modern times two factors have accelerated this process, viz.: (1) the building of railways, which have developed commerce to a very great degree and favoured the large towns at the expense of the small; and (2) the invention of machinery, which has greatly increased the possibility of division of labour and manufactures on a large scale. The old handicraftsman has been superseded by machine labour and the village artisan by the factory hand. At the same time improvements in agriculture and the opening up of new countries have enabled the modern community to gain its food and raw material with a less expenditure of labour force, and the surplus agricultural population has gone to the city. The attractive influences upon individuals have been higher wages, greater scope for the ambitious, and the social advantages of city life.

The general laws of internal migration may be summarized (according to Ravenstein) as follows:—

1. The great body of migrants proceed only a short distance.
2. The process of absorption goes on as follows: The inhabitants of the country immediately surrounding a town of rapid growth flock into it; the gaps thus left in the rural population are filled up by migrants from more remote districts, until the attractive force of one of the rapidly-growing cities makes its influence felt, step by step, to the most remote corner of the land. Migrants enumerated in a certain centre of absorption will consequently grow less with the distance, proportionately to the native population which furnishes them.
3. The process of dispersion is the inverse of that of absorption, and exhibits similar features.
4. Each main current of migration produces a compensating countercurrent.
5. Migrants proceeding long distances generally go by preference to one of the great cities of commerce or industry.
6. The natives of towns are less migratory than those of the rural parts of the country.
7. Females are more migratory than males.

AUTHORITIES.—The statistics of migration are to be found in the official returns of different countries, especially the statistical tables relating to emigration and immigration published by the British Board of Trade, and the Reports (annual) of the Commissioner-General of Immigration of the United States. For general discussion see PHILIPPOVICH. *Auswanderung und Auswanderungspolitik*. Leipzig, 1892. Exhaustive bibliography will be found in article by same author, "Auswanderung," in *Handwörterbuch der Staatswissenschaften*.—R. MAYO-SMITH. *Emigration and Immigration* (with bibliography). New York, 1890. For internal migration see WEBER. *Growth of Cities*. New York, 1899.—RAVENSTEIN. "The Laws of Migration," in *Journal of Royal Statistical Society*, 1885 and 1889.

(R. M.-S.)

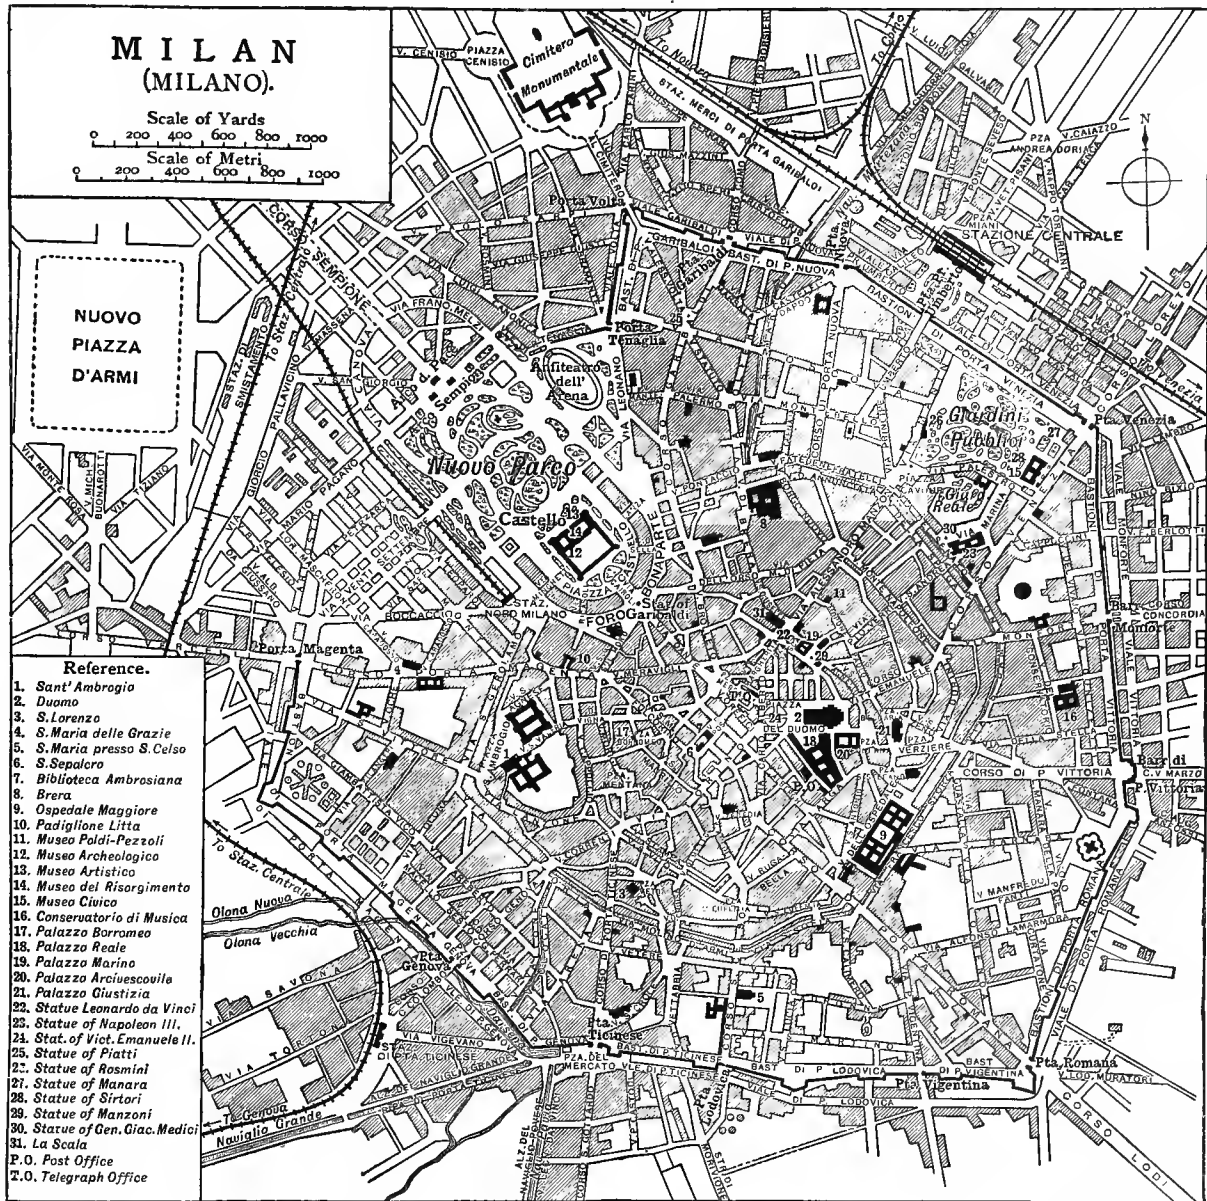

Mikhailovskaya, a Cossack village of Russia, province of Don Cossacks, 43 miles from Shakhtnaya railway station. It is an important centre for grain export. Population, 17,848.

Milan, capital of the province of Milan, Italy, situated in 45° 28' N. and 9° 11' E., on the river Olona. The development of the city, which became noteworthy after the annexation of Lombardy to Piedmont in 1859, continued during the last quarter of the 19th century. The population,

which in 1875 numbered 273,079, reached 500,000 in 1900. The customs circle, which prior to 1898 measured 9½ miles, measures now 18 miles. As early as 1880 the increase of the population necessitated the construction of new quarters (Porta Genova, Principe Umberto, Via Solferino, &c.) within the line of bastions erected by the Spaniards towards the middle of the 16th century; while outside the bastions working-class quarters and industrial establishments grew up. The lack of a general building scheme occasioned confusion, however, and in 1885 the municipal authorities were obliged to lay out the lines of new streets for the whole extra-bastion zone. The scheme, known as the *piano regolatore*, was adopted in 1888, together with a *regolamento edilizio* or building regulation designed to fix the length of the streets and the height of houses, and to secure their solidity and proper drainage. Inside the bastions the *piano regolatore* provided for the completion of the Piazza del Duomo (begun in 1865), and for the formation of a new quarter upon the vast areas of Piazza Castello and Piazza d'Armi. The municipality undertook to furnish the military authorities with a new Piazza d'Armi or military exercise ground, to contribute to the cost of the construction of new barracks in compensation for the military quarters in the Castello Sforzesco, which thenceforward became municipal property. In order to provide for direct communication between this quarter and the centre of the city, it was decided in 1887 to cut a new street, Via Dante, through a zone of old houses. Subsequently, it was thought expedient to lay out the whole Piazza d'Armi as a public garden. This variation of the original plan was completed in 1893. It created in the highest zone of Milan a magnificent quarter, with wide streets, spacious gardens, and private villas, in strong contrast to the narrow and irregular thoroughfares of the old part of the city. The growth of municipal expenditure kept pace with the growth of population and with the structural development of the city. The result was increased taxation within the *octroi* circle, until it became almost intolerable, and large loans had to be effected. In 1898, after several years of party struggle, the *octroi* circle was enlarged so as to include the Corpi Santi with their large industrial population. As a result of the change, municipal revenue has increased so considerably as to assure a surplus after meeting ordinary and extraordinary expenditure out of current income; *octroi* on several prime necessities of life, such as flour, bread, and vegetables, has been abolished, and the collection simplified proportionately. Nevertheless, the agitation connected with this fiscal reform contributed greatly to displace the centre of political gravity in favour of the Anti-monarchical Radicals. Up till 1882 the Moderate or Conservative Monarchical party ruled supreme, both in the municipality and in the parliamentary representation of Milan. In that year the extension of the suffrage and the adoption of the *scrutin de liste* assured to the Radicals four-fifths of the parliamentary representation of the city; and though, after the return to the uninominal ballot, the Conservative party succeeded in regaining four of the six constituencies into which the city was then divided, the Radical, Republican, and Socialist parties, particularly the last, have steadily increased until they secured the whole parliamentary representation of Milan in the general election of June 1900. Similarly, in municipal elections the Socialists and Radicals have gained ground; and though the Moderates continued to hold office, with the help of the Catholic party, until 1899, the municipal elections of December 1899 resulted in a sweeping victory for the Anti-monarchical list, which polled 19,000 votes as compared with 8000 cast for the Conservatives. The success of the popular party was due in part to the defection of the Clericals, but principally to the organization of the

working-class vote and railway vote by the Socialists, to the agitation on the *octroi* question, and to the discontent occasioned by the imposition of a new municipal house-rate. The growth of political Radicalism in Milan has further been favoured by the decadence of the Conservative party organization, and by the unsatisfactory condition of Italian public affairs during the last decade of the 19th century. Nevertheless, manifestations of public

opinion in connexion with the riots of 1898 (which necessitated severe measures of military repression) and with the assassination of King Humbert at Monza (29th July 1900) proved that the bulk of the Milanese population was by no means disaffected towards existing institutions. The municipal elections of 1902 proved that, though still masters of the city, the Radical parties had lost ground. Since 1875 great improvements have been effected in the

means of communication. The omnibus service, organized in 1862, was largely supplanted in 1881 by horse tramways. In 1893 the first electric tramway was tried, and by degrees electric traction on the overhead system has been applied to the whole service. The transformation, completed in 1898, was carried out on the basis of the lines being laid by the municipality while their working was entrusted to the Edison Company. The municipality, however, reserved for itself a share in the profits, so that it possesses more than 68 miles of electric tramways, from which it derives an annual revenue of more than 1,000,000 lire. The number of passengers annually carried by the tramway company is 50,000,000.

Simultaneously with the development of the tram service, the network of railways which makes Milan the most active railway centre of Italy notably increased. In 1882 the important St Gothard line was added to those already converging on the Lombard metropolis from Turin, Venice, Genoa, Piacenza, Como, Varese, and Vigevano. The St Gothard tunnel added immensely to the commerce of Milan by placing it in direct communication with the principal cities of central Europe. At the same time the local railway system has been considerably extended. A further increment of traffic will doubtless follow the opening of the Simplon tunnel in 1905, although even now Milan outdistances all other Italian

cities, including Rome, in respect of passenger and goods traffic and of the postal and telegraphic services. Two other public services, namely, the water supply and the sewer system, have been completely transformed since 1880. The old system of water supply was that of piercing a well for every house built. But with the growth of the city the system was found to be inadequate and dangerous. The municipal technical bureau proposed, as an experiment, to adopt the system of mechanical extraction of water from the deeper strata of the subsoil. This was so successful (1889) that the system has been adopted and extended, so that now deep wells furnish 12,000 litres per minute, with a pressure equal to that of a reservoir at a height of 40 metres. By 1899 the length of water-pipes had increased from 5 miles to 78 miles, and the consumption from 146,000 litres to 4,088,000 litres. Since 1888 the drainage has been greatly improved. Milan has now in all 48 miles of sewers worked on the single-channel principle—that is, a channel which receives all kinds of drainage and rain-water. The chief collectors discharge themselves into the Vettabia, which in its turn communicates with the river Lambro near Melegnano. The Vettabia is an ancient river-bed, adapted centuries ago for irrigation. It irrigates a tract of land nearly 7000 acres in extent, and its surplus waters pass over a further zone of low-lying land 20,000 acres in extent. Thus some 27,000 acres of land are available for the sterilization of Milanese sewage. The growth of population obliged the municipality in 1860 to increase burial accommodation by opening a new cemetery, 120,000 metres in extent, known as the Cimitero Monumentale, at first intended to replace the four old cemeteries in the neighbourhood of the bastions. As its insufficiency became apparent, the abolition of the old cemeteries was suspended until, in 1888, a much larger burial-ground was laid out in the commune of Musocco, 3 miles from the city. This new cemetery is the general burying-ground, the Cimitero Monumentale being reserved for the erection of monumental tombs. An electric tramway connects the two cemeteries. It cannot be said that the development of Milanese hospitals has kept pace with the growth of the population. The Ospedale Maggiore, built in 1456, is still the most important. On the other hand, several special institutes and ambulances have been created by private philanthropy since 1880. The Istituto dei Rachitici, for the cure and education of children suffering from rickets; the Istituto Oftalmico, for eye diseases; and the Padiglione Litta, for surgical operations, deserve mention. The institute for the instruction of the blind, the deaf, and the dumb has been renewed and enlarged. The municipality has further provided a hospital for contagious diseases at Dergano, some distance from the city. Philanthropic institutes such as soup-kitchens, public dormitories, and foundling hospitals have also been established. Two small experiments in the construction of workmen's houses have also been carried out, but, either on account of the special conditions of the Milanese working-classes, or of inherent defects, have not been attended with noteworthy success.

The artistic and scientific patrimony has notably increased since 1875. The Gallery of Brera, founded at the end of the 18th century with works of art accumulated during the suppression of the religious orders, has become one of the most important Italian galleries. Since 1880 it has been enriched with pictures by Titian, Tintoretto, Paris Bordone, Antonello, Cossa, Borgognone, &c.; in 1900 the gallery was enlarged, the number of its rooms being doubled. In 1880 an interesting art collection was bequeathed to Milan by a patrician, Poldi Pezzoli, and has since been opened to the public; it contains many pictures of prime value by painters of the Lombard school, besides bronzes, ceramics, old stuffs, jewellery, glasses, and an important collection of ancient weapons. In 1878 the municipality organized an art museum with objects bequeathed to the city; and in 1899 the collection was placed in the Castello Sforzesco, which has

been restored by the architect Luca Beltrami. In 1895 the Museo del Risorgimento Nazionale was transported thither; in 1896 the school of art applied to industry was installed there; in 1900 the municipal art and archaeological museums were added. In regard to science and scientific collections Milan has made considerable progress. The National Library in the Palace of Brera possesses 250,000 volumes, 126,000 pamphlets, and many manuscripts relating to Lombard history and to the territory of Milan. A Manzoni room has been opened for the collection of all the editions and the autographs of the writings of Alessandro Manzoni, who died in 1873. The Ambrosian Library has continued to receive many important bequests of MSS. and works of art. The reproduction of the *Codice Atlantico* of Leonardo da Vinci, preserved in this library, has reached its eighteenth part; when complete it will constitute a work of more than 1200 plates in heliotype of large form. The civic museum of natural history, founded about 1850 with small resources, has been increased by donations and bequests, notably by that of Count Turati, who presented to the municipality his ornithological collection, one of the richest in Europe. In 1888 the museum was installed in a special edifice in the public gardens, where the mineralogical and fossil collections are displayed to advantage. The Brera Observatory was furnished in 1882 with a large equatorial refractor, having an objective 18 Paris inches in diameter. The Milanese Polytechnic, founded in 1865 by the mathematician Brioschi, has greatly developed. A considerable number of monuments have been erected in the gardens and squares. The principal are the equestrian statues of Victor Emmanuel II., Garibaldi, and the monument commemorative of the insurrection of 1848 against the Austrians. Other statues are those to Alessandro Manzoni, Giuseppe Parini, Antonio Rosmini, G. B. Piatti (inventor of the drills used in boring the Cenis tunnel), Antonio Stoppani, Generals Sirtori and Medici, Luciano Manara, and Francesco Brioschi. The equestrian statue of Napoleon III. is still in the Senate courtyard awaiting its transfer to the position assigned to it in front of the Arco della Pace, through which the allied French and Italian armies entered Milan after the battle of Magenta. The ancient monuments have, on the whole, been well cared for. Besides the above-mentioned restoration of the Castello Sforzesco, works of restoration have been executed in the churches of Santa Maria delle Grazie (in terra-cotta), of Santa Maria presso San Celso, and of San Sepolcro. The belfry of San Gottardo has been repaired, Palazzo Marino (the seat of the municipality) completed, and various repairs carried out in the Palazzo dei Giureconsulti and the Loggia dei Notai. Unfortunately, Milanese archaeologists have not succeeded in every case in preventing acts of vandalism during the transformation of the city. Thus, in 1900, the ancient Porta dei Fabbri was demolished—one of the last traces of the walls rebuilt by the Milanese after the destruction of their city by Frederick Barbarossa. Milan has retained its position as musical centre of Italy, and as one of the chief musical centres of Europe. The Scala Theatre, with a municipal subsidy, maintained its traditions. In 1897 the municipality withdrew its subsidy, and the Scala remained closed during the season 1897–98; but, owing to private initiative, the theatre was reopened for the triennium 1898–1901 with a limited subvention from the commune. The result of this experiment assured the continuance of the traditions of the Scala.

Province of Milan.—The conditions of Lombard agriculture in the Milan district have been somewhat modified by the extension of irrigation and the development of intensive culture. The territory of which Milan forms the centre has been for centuries divided into a dry zone, extending from the Lower Alps to the city, and an irrigated zone, stretching from the city to the Po. In 1860 the Cavour and Villoresi canals extended the irrigated zone towards the north. Milan still remains the centre of the most rationally irrigated districts in Europe. The potentiality of the north Italian canals is surpassed only by that of the great Ganges canal constructed by the British in the second half of the 19th century. The oldest canals lead from Lakes Maggiore and Como; the Muzza canal, leading from the Adda, existed earlier than the year 1000, and has now an average potentiality in the summer season of 90 cubic metres per minute. The Naviglio Grande, begun for purposes of irrigation in 1185, was adapted also for navigation earlier than the 15th century. The Martezana canal was constructed at the end of the 15th century, Leonardo da Vinci taking part in its preparation. These two latter canals, leading respectively from the Ticino and the Adda, discharge themselves into the Pavia canal, which in its turn flows into the Ticino at a short distance from the Po. Besides these great arteries, irrigation is effected with water drawn from springs and wells, which, on account of the natural slope of the Lombard plain, are able to irrigate land at several kilometres' distance. This system is facilitated by the so-called "right of passage" or "right of aqueduct" created in Lombardy, and now included in the civil codes of several nations. The rent of irrigated land varies from 8 to 11 lire per perch (120 to 165 lire per hectare)—scarcely one-half of the rent demanded a few years back. This reduction has led to

the intensification of pasturage and grazing products; but these, in their turn, have fallen in price on account of the difficulty of exportation. The Lombard peasants hold a high place amongst Italian agriculturists, and have been instrumental in introducing superior systems of agriculture into Lazio, Apulia, and Sardinia. The dry zone has undergone little change either as regards culture or land tenure. Silkworm rearing is still the chief industry of the region, the land being held on the *mezzadria* or *métayer* system, according to which the products of the soil are divided between landlord and tenant. The fall in prices has caused a diminution in rents and incomes, and has stimulated emigration to South America.

Most noteworthy, too, has been the industrial development of Milan, with its suburbs and neighbouring towns, such as Monza, Gallarate, Saronno, Busto Arsizio, and Legnano. Machine-making on a large scale is carried on by firms widely celebrated for the construction of locomotives, railway trucks and carriages, steam boilers and motors, turbines, pumps, metal bridges and roofs. A number of large turbines for the hydraulic works at Niagara Falls were constructed at Milan in 1900. Minor industries are represented by workshops for the production of surgical, musical, and geodetic instruments; of telephone and telegraph accessories; dynamos, sewing machines, bicycles and automobiles. There is also a large carriage industry. In textile industries silk holds the first place. The amount of silk handled and woven in Milan is greater than that dealt with at Lyons. Milan, indeed, supplies 9,000,000 out of the 24,000,000 kilogrammes produced in Europe. Spinning and twisting (Italy produces 50,000,000 kilogrammes of cocoons, which supply work for 60,000 basins and 1,600,000 spindles) are as highly developed as the weaving industry. Cotton-spinning is represented by 1,000,000 spindles in Lombardy alone. At Milan, headquarters of the industries, cotton weaving, dyeing, and printing are extensively carried on. Linen, flax, jute, and wool are also spun and woven. The Milanese manufactures of articles in cautchouc and of electric cables have acquired a world-wide reputation. In typography Milan is renowned principally for its musical editions and for its heliotype and zincotype establishments. There is besides a huge production of posters for advertisement. The manufacture of furniture of all kinds is still extensively carried on, Milan being the chief Lombard market and centre of exportation. The towns of Cantù, Meda, Lissone, and Carugo supply Milanese firms with most of their merchandise, the furniture being made by the workmen at their own homes with materials supplied by the Milanese buyers, who also advance the capital necessary for working expenses. House industry is still widely diffused in Milan itself, especially as regards working in gold, silver, vulcanite, bronze, and leather. The motive power for much of the house-industry is supplied by electricity, 7000 kilowatts being thus employed. The electricity is furnished by the hydraulic works at Paderno, 24 miles from Milan.

(L. Br.)

Milan Obrenovitch IV. (1854–1901), king of Servia, was born 22nd August 1854, at Jassy. He was the grandnephew of the famous Milosh, whose brother Jefrem (d. 1856) had a son, Milosh (1829–1861), who married Maria Katardzi, a Moldavian. Milan was their son. While still very young, he lost both his parents, and was adopted by his cousin, Michael Obrenovitch, who returned to Servia on the expulsion of the Karageorgevitches in 1858 and became ruling prince on the death of his father, Milosh, in 1860. During the reign of Michael young Milan was educated in Paris, at the Lycée Louis-le-Grand, where he displayed considerable precocity, but he was only fourteen years of age when in 1868 his cousin was assassinated and he succeeded to the throne under a regency. In 1872 he was declared of age, and taking the reins of government into his own hands, soon manifested great intellectual power, coupled with a passionate headstrong character. Eugene Schuyler, who saw him about this time, found him "a very remarkable young man . . . singularly intelligent and well informed." By a careful balancing of the Austrian and Russian parties in Servia, with a judicious leaning towards the former, Prince Milan was enabled in 1878, at the end of the Turkish war, to induce the Porte to acknowledge his independence, and was proclaimed king in 1882. (The history of his reign is told in detail under SERVIA.) Acting under Austrian influence, King Milan devoted all his energies to the improvement of means of communication and the development of natural resources, but the cost, which was unduly

increased by reckless extravagance, led to proportionately heavy taxation. This, coupled with increased military service, rendered King Milan and the Austrian party most unpopular; and his political troubles were further increased by the defeat of the Servians in the war against Bulgaria, 1885–86. In 1885 (September) the union of Rumelia and Bulgaria caused widespread agitation in Servia, and Milan precipitately declared war upon his kinsman Prince Alexander on 15th November. After a short but decisive campaign, the Servians were utterly routed at the battles of Slivinska and Pirot, and Milan's throne was only saved by the direct intervention of Austria. Domestic difficulties now arose which rapidly assumed a political significance. In October 1875 King Milan had married NATALIE, the sixteen-years-old daughter of Peter Ivanovich Ketchko, a Moldavian Boyar, who was a colonel in the Russian army, and whose wife, Pulcheria, was by birth Princess Sturdza. A son, Alexander, was born in 1876, but the king and queen soon showed signs of friction. Milan was anything but a faithful husband. Queen Natalie was greatly influenced by Russian sympathies; and the couple, ill-assorted both personally and politically, separated in 1886, when the queen withdrew from the kingdom, taking with her the young prince, Alexander, afterwards king, then ten years of age. While she was residing at Wiesbaden in 1888, King Milan succeeded in recovering the Crown Prince, whom he undertook to educate; and in reply to the queen's remonstrances, he exerted considerable pressure upon the metropolitan, and procured a divorce, which was afterwards annulled as illegal. King Milan now seemed master of the situation, and on 3rd January 1889 promulgated a new constitution much more liberal than the existing one of 1869. Two months later (6th March) he suddenly abdicated in favour of his son, a step for which no satisfactory reason was assigned, and settled as a private individual in Paris. In February 1891 a Radical ministry was formed, Queen Natalie and the ex-metropolitan Michael returned to Belgrade, and Austrian influence began to give way to Russian. Fear of a revolution and of King Milan's return led to a compromise, by which in May 1891 the queen was expelled, and Milan was allowed a million francs from the civil list, on condition of not returning to Servia during his son's minority. Milan in March 1892 renounced all his rights, and even his Servian nationality. The situation altered, however, after the young King Alexander in April 1893 had effected his *coup d'état* and taken the reins of government into his hands. Servian politics began to grow more complicated, and Russian intrigue was rife. In January 1894 Milan suddenly appeared at Belgrade, and his son gladly availed himself of his experience and advice. On 29th April a royal decree reinstated Milan and Natalie, who in the meantime had become ostensibly reconciled, in their position as members of the royal family. On 21st May the constitution of 1869 was restored, and Milan continued to exercise considerable influence over his son. The queen, who had been residing chiefly at Biarritz, returned to Belgrade in May 1895, after four years' absence, and was greeted by the populace with great enthusiasm. In 1897 Milan was appointed commander-in-chief of the Servian army. In this capacity he did some of the best work of his life, and his success in improving the Servian military system was very marked. His relations with the young king also remained good, and for a time it seemed as though all Russian intrigues were being checked. The good relations between father and son were interrupted, however, by the latter's marriage in July 1900. Milan violently opposed the match, and resigned his post as commander-in-chief; and the young king banished him from Servia and threw himself into the arms of Russia.

Milan retired to Vienna, and there he died unexpectedly on 11th February 1901. Milan was an able, though headstrong man, but he lived a scandalously irregular life, and was devoid of moral principle. In considering his relations with his young son, it must be remembered that in the dynastic and political condition of Servia natural feeling was inevitably subordinated in Milan to other considerations.

Milazzo, a seaport town of the province of Messina, Sicily, Italy, 22 miles west of Messina by rail. There is a good harbour, which can be entered by vessels drawing 20 feet, but the trade is decreasing; in 1888 the port was entered by 1523 vessels of 147,150 tons, in 1899 by 515 vessels of 82,600 tons. The exports are wine, tunny, oranges, lemons, and other fruit, and olive oil. Population (1881), 9468; (1899), 13,000.

Miles, Nelson Appleton (1839—), American soldier, was born in Westminster, Mass., on 8th August 1839. A civilian, and engaged in mercantile pursuits when the Civil War began, he entered service in September 1861 as a lieutenant in the 22nd Massachusetts volunteers, won campaign distinction, and was commissioned, in September 1862, colonel of the 61st New York volunteers. He was advanced to brigadier-general of volunteers in May 1864, and to major-general in October 1865. He fought in most of the great battles of the army of the Potomac, and at the end of the war was appointed (July 1866) a colonel of regulars. Promoted to U.S. brigadier-general (December 1880), and major-general (April 1890), he succeeded to chief army command in 1895. He was successful (1869–86) in suppressing Indian outbreaks, and commanded in Chicago during the railway riots in July 1894. He was in nominal direction of operations during the war with Spain, 1898, though tardily sent to the front. He was raised to the rank of lieutenant-general commanding in June 1900.

Milford, contributory parliamentary borough (Pembroke district) and seaport of Pembrokeshire, Wales, about 8 miles west-north-west of Pembroke on Milford Haven; a terminal station of the Great Western railway. New water storage has been constructed, with a capacity of 3,000,000 gallons. Mackerel are brought here from the Irish coast and despatched by rail to London and other centres. In 1890, 1705 vessels of 350,504 tons entered and 1709 of 350,375 tons cleared; in 1900, 1206 vessels of 272,124 tons entered and 1153 of 265,525 tons cleared. Population (1891), 4070; (1901), 5102.

Milford, a town of Worcester county, Massachusetts, U.S.A., in the southern part of the state. Within its area of 16 square miles are a large rural population and a village of the same name as the town. Three railways traverse the town—the Boston and Albany, the Grafton and Upton, and a branch of the New York, New Haven and Hartford. It manufactures boots and shoes, besides a variety of other goods. Population (1890), 8780; (1900), 11,376, of whom 3342 were foreign-born.

Military Law (see also *Ency. Brit.* vol. xvi.).—Military law is “the law which governs the soldiers in time of peace and in war, at home and abroad.” *Definition.* At all times and in all places the conduct of officers and soldiers as such is regulated by military law.” This is the definition given in the opening chapter of the *Manual of Military Law*, which is issued under the authority of the War Office, and which is the text-book used by all courts-martial. The definition is, however, somewhat too wide, and places the British soldier on the level of the French soldier, who is amenable to military tribunals at all times and for all breaches of the law, whether of a civil or of a military character. The British system does not exclude in time of peace the

action of the civil courts. In time of peace all persons who belong to the military class in France and other Continental countries are judged by military law and by military courts. There is also in most Continental countries an intermediate stage between war and peace known as an *état de siège*, which may be declared for a fixed period for a district, or even a city, by reason of domestic insurrection or the presence of an enemy. It requires legislative enactment. Thirdly comes a state of war, when the military authorities are supreme; and whilst they can call upon the civil power to act in concert with them, the military authority is final. This is a brief summary of the system of military law that prevails in most countries of the Continent. The cardinal point of difference between the British and the Continental systems lies in the fact that in the United Kingdom the soldier is not only a soldier, but a citizen also; and although he may be tried for civil offences by a military tribunal, the power is not exercised in all cases. Thus treason, treason-felony, murder, manslaughter, rape, are brought before a civil court in times of peace, if the offence is committed in the United Kingdom, or if it is committed anywhere else in the king's domains, except Gibraltar, within a hundred miles from a place where the offender can be tried by a civil court. Minor civil offences, when not committed within military lines, or when the person affected by the offence is a civilian, or when it is a case for a jury, or where intricate questions of law may arise, may also be brought before a civil tribunal. But an offence, of whatever nature, committed on active service would be brought before a military tribunal.

The British army estimates for 1902 provided for a force of 420,000 men, 219,000 being for ordinary army service and 200,300 for war service, as compared with 180,513 in the year before the South African war. Militia, yeomanry, and volunteers have all increased in numbers as well as the regular forces. This increase in all the British military forces has rendered necessary a further development of military law. Martial law has also come into unusual prominence, and it is treated under its own heading.

The courts-martial in the year preceding the South African war were over 8000 in number. The number in 1901 exceeded 20,000. The number of field general courts-martial greatly increased in consequence of the war, and a field general court-martial has become of special importance. It is convened (1) by any officer in command of a detachment or portion of troops beyond the seas when not on active service, where complaint is made to him that any offence has been committed by any person under his command against the property or person of any inhabitant or resident in that country; or (2) by the commanding officer of an army corps or portion of a corps on active service, or by any officer in immediate command of a body of forces on active service where it appears to him on complaint or otherwise that a person subject to military law has committed an offence. The officer must be satisfied that it is not practicable, with due regard to the public service, to try the person by an ordinary court-martial. The quorum of the court is three, if consistent with military exigencies, and each member must have held a commission for not less than a year. The quorum may be reduced when the public service requires it. The procedure of ordinary courts-martial is observed as far as possible, and the proceedings always should be in writing when possible. But in the circumstances in which these courts are assembled, it is not always possible to adhere to the technical rules which obtain in the ordinary tribunals, although the broad principles are not violated. The evidence on a field

Field general courts-martial.

general court-martial is taken on oath. The prisoner may cross-examine the witnesses for the prosecution, and may call any available witnesses for his defence. The prisoner is allowed to address the court in his own defence.

Important changes were made in the system of courts of inquiry by an Army Order of 10th February 1902. A

Courts of inquiry. A court of inquiry is and has been an assembly of officers directed by a commanding officer to collect evidence and report with respect to a transaction into which he cannot conveniently himself make inquiry. But now, whenever any inquiry affects the character or military reputation of an officer or soldier, full opportunity must be given him of being present at the inquiry and of giving any evidence, or making any statement, or cross-examining adverse witnesses, or producing witnesses on his own behalf. Evidence may now be ordered to be taken on oath if the assembling officer thinks the case requires it. No proceedings of a court of inquiry, no confession, statement, or answer is admissible in a court-martial. But an officer or soldier tried by court-martial in respect of matter which has been the subject of a court of inquiry is entitled to a copy of the proceedings on payment of the cost of the copy. The finding and sentence are only valid after confirmation by the proper military authority. A sentence of death or penal servitude can only be confirmed by the general or field officer in command of the forces with which the prisoner is present. The rule which allows the prisoner and his wife to tender their evidence on oath under the recent Act as regards evidence is applicable to field general courts-martial. It is useful to note that the Army Act, sec. 70, enables His Majesty to make new provisions under the hand of a Secretary of State for, amongst other things, the assembly and procedure of courts of inquiry. The power to make changes by Army Order or rule is only limited by the principle that the rules must not be contrary to or inconsistent with the Act.

The Militia Act, 1882 (sec. 12), confined liability to the service of the militia to any part of the United Kingdom, but no part of the militia could be ordered out of the United Kingdom. The Reserve Forces and Militia Act of 1898 now enables them by voluntary offer to extend their services to any place out of the United Kingdom. Under the recent Act the volunteers also can be accepted for service out of the United Kingdom for a period not exceeding one year, whether an order embodying the militia is in force or not at the time. Militia officers are at all times subject to military law, and militiamen during their preliminary training, during their annual training when acting with the regular forces, and during their embodiment. The old system of ballot for militia services (which is generally thought to be the sound basis of a regular army, because it would provide not only a system of home defence, but also reinforcements for the regular forces) would require no addition to the Militia Act, as already there is legislative power to revive the militia ballot.

The yeomanry stand on the same footing as the volunteers, and may be considered a cavalry branch of the volunteer force; so these auxiliary forces rank equally in military law. No limit is placed on their number, and they only require the acceptance of their services by the King. They are not held to be effective unless they do a yearly training of five consecutive days, or six days in the year. The yeomanry are included in the Army Act with the militia and volunteers as "auxiliary forces" when employed in military service—that is, they become subject to military law.

The Reserve Forces Act, 1882, established the reserve for the regular forces and the militia. The main object of

the Reserve Forces Act at the date of its enactment was to aid the civil power in the preservation of the public peace. But by the Reserve Forces and Militia Act, 1898, any man belonging to the first class of the army reserve whose character on transfer to the army reserve is good shall, if he so agrees in writing, be liable for the first twelve months of his service in that reserve to be called out on permanent service without being called out by proclamation or without the meeting of Parliament; and in case there is a state of war between His Majesty and any foreign power, the service of a reserve man may be prolonged for a further period not exceeding twelve months, or his services may be dispensed with by the competent military authority.

By the Reserve Forces Act, 1899, if serving out of the United Kingdom, he may at his own request be transferred to the reserve without being required to return to the United Kingdom. Volunteers are a voluntary service, but in case of actual or apprehended invasion of any part of the United Kingdom they may be called out for actual service (Volunteers Act, 1863). They are subject to military law when on actual military service, when being trained or exercised with any portion of the regulars, or with any portion of the militia when subject to military law. But any volunteer may (since 1895) offer himself for active military service whenever an order for the embodiment of the militia is in force.

In an authoritative report published by the Norwegian Government, and compiled by a trained Norwegian lawyer, who visited the various countries, the systems of twenty-two states are reviewed. The earliest military law still in vigour is found in Norway and Denmark, and dates from 1683, while England and Sweden date from 1881. Sweden has a military penal code, and England is ruled by the Army Act. There are two kinds of military courts of first instance: (1) those belonging to separate military bodies, such as divisions, brigades, regiments; (2) those having jurisdiction in a certain territory, and their seat determined. In times of war the courts must follow the military bodies. In Bavaria and Switzerland a military jury is attached to a court-martial. In several states "auditors," i.e., judicial guides, are attached to courts-martial. In some a military jurisconsult (lawyer) is attached as judge, always a fixed post. This obtains in Sweden, Finland, Austria-Hungary, Switzerland, and Portugal. In Norway, Denmark, Sweden, Finland, Belgium, Great Britain, Germany, Austria, United States, Spain, Würtemberg and Switzerland, the presiding officer is chosen for the single trial. In other states the military judges are appointed for a certain term, usually six months. The quorum of judges required on military courts on the Continent differs. Seven judges sit in Belgium, Holland, France, Spain, Portugal, Greece, Turkey, and Würtemberg; three only, in cases of ordinary offences committed by non-commissioned officers and soldiers in Switzerland, Russia, the United Kingdom, United States, and Bavaria. In grave cases in the United Kingdom five to nine sit, nine in Russia, five to thirteen in the United States. In Norway and Denmark the court is of thirteen up to twenty-five, unless replaced by a commission and a military lawyer.

In Norway, Denmark, Sweden, Finland, and Bavaria and other places in Germany, special summary courts-martial are held when necessary. Certain forms and legal guarantees are then dispensed with. Such are held in Belgium and Holland "in a town or place in state of siege." *La Prévôté* is a special court of a judge assisted by a registrar, for vagabonds, servants, sutlers, and with a very limited competence over

The reserve.

The volunteers.

Summary courts-martial.

soldiers who have committed a petty offence, held in time of war in France, Rumania, and Greece.

The United Kingdom has a summary court-martial when the regular court-martial cannot be held without injuring the military service. In the United States there are the "field officers' court-martial" and "military commission," consisting of three officers. The second is for judging spies, and some other matters that escape the jurisdiction of the regular courts-martial. A special military tribunal in Germany judges the officials attached to the army. *Courts of Honour* exist in Russia, Germany, Bavaria, Württemberg, Austria-Hungary, and Spain. Great Britain and the United States have the system of a "court of inquiry." This was only a commission of inquiry, but it is now public, the accused is present, and the witnesses are sworn.

Soldiers not on active service, says the Swedish report, should be answerable for infractions of common law, under the jurisdiction of the civil courts. All infractions of military order or discipline committed by soldiers, whether on active service or no, should be judged by military courts. In time of war, it is equally admitted, military courts must judge all offences, even offences at common law, committed by soldiers forming part of an army on campaign. The difference lies in regard to offences committed in time of peace. Sweden, Great Britain, Italy, and the United States, as a general rule, place offences against the common law (*infractions de droit commun*) in time of peace under the jurisdiction of the civil courts. In the United States offences against good order, in Great Britain personal offences (such as drunkenness), are judged by court-martial. In most other states the general rule is that soldiers, even in time of peace, if on actual service, are judged by courts-martial. In the case of complicity between a soldier and a civilian, sometimes one is judged by a military, and the other by a civil court (in Germany, Switzerland, and Spain), sometimes both by a military court (Belgium, France, Italy, Servia, Rumania, and Greece); sometimes it depends on the nature of the crime—in the United Kingdom, United States, Sweden, Finland, Holland, and Portugal. In Norway a mixed tribunal judges them.

The procedure in military courts differs according to the countries. In some systems (a) the examination and preparation of evidence are confided to a *juge d'instruction*; (b) in other systems they are confided to a special commission of inquiry; (c) again, in other places they are left to the court-martial itself that will judge the case. The United Kingdom and the United States follow the last plan. There is no preparatory examination in these two countries. A commission of inquiry for the preparation of evidence is held in Norway, Denmark, Germany, Württemberg, Austria-Hungary, Servia, Belgium, and Holland. An auditor directs these courts of inquiry. In Russia an officer acts as *juge d'instruction*; in grave cases he must be a military juriconsult. In France, Italy, Spain, Rumania, Greece, and Turkey an officer acts as *juge d'instruction*.

The proceedings before a court-martial are usually public, except in the case of matters that offend morality, compromise public order, or where publicity is considered injurious to the interests of the service (cases of discipline, disclosing plans, &c.). This does not apply (except in Great Britain and the United States) to the proceedings before the courts charged with preliminary investigation. In several states, *i.e.*, Norway, Denmark, Holland, Austria, Servia, Germany, and Württemberg, the public prosecutor is also the counsel of the accused. The auditor who directs the court of inquiry fills these offices (except in cases of small importance in

Germany and Württemberg). In other states there is a special office of public prosecutor. In France he is an officer, and in Spain, Portugal, Rumania, Greece, and Turkey. In Russia, Belgium, Bavaria, Switzerland, and Italy he is a military lawyer. In these countries the accused has the right to choose a counsel, or one is assigned him. In the United Kingdom and the United States, when the matter is grave, the direction of the case is put in the hands of a judge-advocate. In the United States the judge-advocate is the public prosecutor.

There is no superior tribunal to which to appeal in Denmark, Great Britain, and the United States. In Denmark the cases are sent to the auditor-general, who can annul if there is error in form, and send back the case to be tried anew. In Great Britain and the United States judgment in ordinary cases must be confirmed by the commanding officer by whose order the court was called. He can lighten the sentence. In certain cases of great gravity it must go on to the head of the State, after passing through the revision of the judge-advocate-general, who is the constitutional adviser of the Crown as regards courts-martial from the point of view of legality. There is also in these two countries a special revision of judgments in the judge-advocate-general's office. This revisional power is the safeguard of military justice, as all decisions are reviewed, and if any illegality is pointed out the proceedings are consequently quashed. The effect of this disapproval is not merely to annul the proceedings, but it also prevents the accruing of any disability or forfeiture. The British judge-advocate's office has been much strengthened. It now consists of—(1) The judge-advocate-general (one of H.M. judges). (2) A deputy judge-advocate-general, who is a trained lawyer. (3) A deputy judge-advocate, also a trained lawyer. (4) A military officer of the rank of colonel who has been called to the Bar. (5) In South Africa (since 1899, and on a five-years appointment from 1902) a colonel who has been called to the Bar.

In Germany there is no appeal except for officials attached to the army. In Austria-Hungary the sentence can be lightened by the commanding officer. It can also be returned for trial by a superior court if it appears to him too light. In Spain all judgments have to be confirmed, and if confirmation is refused, it is carried before the supreme court of the navy and army. The condemned has no power of appeal himself, but all cases of death or life sentences go before the supreme court of the navy and army. Russia only requires the confirmation of the commanding officer. In France, Rumania, and Greece all condemned prisoners in time of peace can demand a court of revision, composed of a general and four superior officers. In time of war the court may be composed of three.

Certain forms of punishment, in all countries but the United States, can be given by the superior officer, without judicial intervention, for small purely military offences, where a summary procedure is required. The offender, if he prefers, may be carried before court-martial. The punishment is immediately carried into force, but the person punished can complain to higher military authority. In that case, if the complaint is not admitted, the punishment is enhanced. The commonest of these disciplinary punishments are deprivation of liberty, confined to barracks, arrests and prison. Certain special punishments obtain in certain countries—for instance, imprisonment in Turkey may be accompanied by a bread and water diet; and officers in Finland and Russia may be deprived of advancement.

Military Tactics. See TACTICS.

Militia.—The militia of the United Kingdom, commonly so called, is the general or regular militia, as distinguished from the local militia, which was established in the year 1808, and which, though in abeyance, might still legally be raised. It consists of a number of officers, non-commissioned officers, and men, serving under special enactments and regulations, formed into corps or battalions, and trained as soldiers for the purpose of augmenting the military strength of the country in case of national danger or emergency. Although the force is very ancient, being the direct descendant of various levies compulsorily raised for national defence from the earliest times, the title militia first appears in the year 1590, and constantly occurs in parliamentary reports in 1640 and 1641, at which time it was referred to as a new word. The actual origin of the militia is lost in antiquity.

The Roman invasion was stoutly resisted by armed tribes resembling a militia, and possessing both organization and military ability. The inhabitants of Britain are described by

History. historians as a military people, well armed, and adopting tactics in which, by means of chariots, they combined great mobility with the steadiness of foot soldiers. With the advent of the Saxons began the county organization, with which the militia is still closely identified, and the development of a military force called "The Fyrd," easily recognizable as identical in principle with the modern militia. This was the force which King Alfred reorganized. Under this reform was established a general liability to military service on the part of every able-bodied male between the ages of 16 and 60. Although the title of "The Fyrd" survived until long after the Norman Conquest, the force established by King Alfred was known as the general levy, which was bound to appear armed when ordered to aid in suppressing domestic riots as well as in defending the realm against invasion by foreign foes. Service was restricted to the counties except in case of invasion, when it was extended to the whole kingdom. For centuries these remained with little alteration as the principles governing the national forces of the kingdom, and form in effect with certain developments the basis of the modern militia system. The Norman Conquest was immediately followed by the introduction of the feudal levy in addition to the general levy, the distinction between these forces being that while obligation to serve in the latter rested upon every male within certain limits of age, service in the feudal levy depended upon tenure of land under the king as feudal lord. The general levy probably constituted the larger part of the infantry, while the feudal levy consisted of the knights who, with their retainers, mounted and armed, were bound to attend the king at their own expense. Thus early, as in the present day, the question of service abroad as well as at home was raised, with the result that the feudal tenants successfully refused to serve out of the kingdom. Personal service formed the basis of both levies, but service by deputy, or payment in lieu of personal service, and the calling out of a quota only, were allowed from very early times. The feudal levy was discontinued during the Commonwealth and abolished at the Restoration; but liability to serve in the general levy has never been extinguished, but remains in the statutory and practical form of liability to serve both in the general and local militia. Inspections of arms and the assembly and training of the men raised under this national system were secured from time to time by means of "assizes of arms," "views of armour," "commissions of array," and "commissions of musters," dating from early in the 12th century down to the 16th century. The machinery employed to carry out the law formed the basis of the existing procedure for the enforcement of the ballot for the militia, which thus bears a strong resemblance to the means adopted from ancient times. These constitutional powers were frequently abused by "electing" or impressing men to serve out of the kingdom, but this was checked in the year 1327 by an Act of Parliament, which strictly regulated the scope and limits of military service within the kingdom at the charge of the parishes or counties, but provided for service abroad at the charge of the Crown. "Commissions of musters" were a development of preceding measures for raising men and material for military service, under which the commissioners registered and mustered persons liable to serve, sorted them into bands, and trained and exercised them at the charge of the county. These bands became known as train or trained bands, and were mustered annually. With them were associated lieutenants of counties, first appointed in 1549 by Edward VI., subsequently in Queen Mary's reign called lord-lieutenants, and after the Restoration appointed as statutory officers for the

militia, their commissions at the present day being issued under the Militia Act. There does not appear to have been any clearly defined regimental organization in existence until these bands or companies were called into active service, but the Acts of the Commonwealth supplied this defect, and initiated a permanent regimental system. One of the earliest attempts to reform the force since the time of King Alfred was made by Charles I. in 1629, when Orders in Council were issued instructing lord-lieutenants to put the militia on a better footing and to fill up vacancies among the officers. Cromwell subsequently issued similar orders couched in strong terms, though under the Commonwealth the duties of lord-lieutenants were not recognized, the militia being raised by commissioners. At the Restoration an Act was passed declaring that the control of the militia was the prerogative of the king, and in the following year another Act, with subsequent amendments, established the militia upon the basis on which it rested until 1757, the year of Pitt's great reform. Charles II. transferred the control of the militia to the lord-lieutenants, but lowered the military status of the force by requiring all offences to be punished by the civil magistrate. To this cause is attributed the disrepute into which the militia fell and the inefficiency it displayed, with the exception of the trained bands of London, until it was reorganized in 1757. Under the Act of 1662 all train bands were discontinued in the counties, but those of London, with their auxiliaries, remained until 1794, when they were reorganized as the City of London militia. In 1688 an Act was passed raising the militia for one year, and for some time this Act became an annual one. In 1690, on the occasion of the French invasion, the militia was embodied; and again in 1715 and 1745 during the troubles caused by the Old and Young Pretenders. In a pamphlet of 1712 the English militia was estimated at 7450 horse and 84,391 foot soldiers. From 1715 until 1734, and again from that year until 1757, with the exception of 1745, no votes were taken in Parliament for the militia.

The foregoing remarks apply only to the English militia and its predecessors. Ireland and Scotland did not furnish any regular militia until 1715 and 1797 respectively, although in Scotland militia existed long before 1797, *e.g.*, in Perthshire in 1684; and in addition corps of fencibles were raised and embodied. The Irish militia when first raised in 1715 was restricted to Protestants between the ages of 16 and 60, who were bound to appear or provide substitutes. The force was not made subject to military law, but various military offences were punishable by fine or imprisonment. Several amendments and other Acts followed until 1793, when a new Act was passed providing for raising a force of militia by ballot among men between the ages of 18 and 45, to serve for four years. Each county was liable to a fine of £5 for each man deficient, and enlistment in the army was prohibited. Other amendments followed from time to time, and notably one in 1797 abolishing religious restrictions for the supplementary militia, and another in 1802 removing the same restrictions in the case of the general militia. Finally, all the Acts were consolidated in 1809 by an Act which fixed establishments, provided for raising the men by ballot, but gave power to the lord-lieutenant to authorize voluntary enlistment by means of bounties, and also to suspend the raising of any regiment. The Scottish militia was at first raised by ballot among men between the ages of 19 and 30. In 1802 former Acts were replaced by an Act providing for the organization of the militia on a basis similar to that on which the militia of England was organized by the Consolidation Act passed in that year.

The immediate cause of the organic reform carried out in 1757 was the disclosure of the inefficiency of the militia during the rebellion of 1745. The Act of 1662 followed the old law by requiring owners of property to furnish men, horses, and arms in proportion to the value of their property, and the liability of persons of small property was to be discharged out of a rate levied in the parish. This was entirely altered in 1757, a liability on the part of the county or parish being substituted for a liability on the part of individuals. Each county was required to furnish a quota apportioned among the various parishes; men were to be chosen by lot to serve for three years (this being the first provision of a fixed term of service) or to provide a substitute, and vacancies were to be filled from time to time by a like process of ballot. The system thus legalized is practically the existing though suspended ballot system. The force was to be annually trained and exercised for a limited period, and in case of invasion or danger thereof, or in case of rebellion, the Crown could order it or any portion of it to be embodied; and during embodiment it was subject to the Mutiny Act. Under this Act 30,000 militiamen were raised by ballot and embodied from 1759 to 1763. This force was exclusively "Protestant," and remained so until 1802. The service of the militia as thus arranged remained nearly in the same state until 1870. Pitt's reform, however, was followed by numerous amendments, new enactments, and other changes, of which the following is a summary in chronological order:—

1758. Volunteers officially recognized as counting towards the quota.

1761. Raising of quota made compulsory on counties under penalty of fines.
Mutiny Act applied to militia when out for training as well as when embodied.
1775. (American War.) Act passed empowering embodiment of militia in case of colonial as well as domestic rebellion.
1786. Charge on parishes for storage of arms, &c., transferred to counties.
1795. Enlistment into regulars encouraged.
1796. Supplementary militia formed, consisting of 63,878 men.
1798. (Irish Rebellion.) English militia volunteered for service in Ireland.
1799. Irish militia volunteered to serve in Great Britain. 15,000 militiamen volunteered to regular army.
1803. 45,492 men raised for militia by ballot, but of these 40,998 were substitutes.
1805. Militia affiliated to line for purposes of recruiting for regulars.
1806. Training Act to raise by ballot 200,000 men to be trained for one whole year, and then to discharge them from training for two years.
1808. Difficulties having arisen under above Act, local militia (which is in effect the old general levy) established in addition to general militia then embodied. 27,000 militiamen volunteered to regular army during preceding twelve months.
1811. English militia, hitherto not liable to serve out of the kingdom, now made liable to serve in any part of the United Kingdom under certain restrictions, which were subsequently (in 1859) removed.
Method of obtaining men from militia for regulars further systematized.
1812. In this year there were 250 regiments of local militia, with an establishment of 240,388 men and 214,418 actually enrolled.
1813. During ten years, from 1803 to 1813, nearly 100,000 militiamen joined the regular army.
Act passed to enable militia to serve abroad as militia with their own officers. Three strong battalions joined the British army in France.
1815. Militiamen recruited in great numbers the army which fought at Waterloo.
Local militia ceased to be raised.
1816. Local militia and Ballot Act suspended.
General militia disembodied.
- 1820-21-25. Militia called out for training.
1829. Act passed suspending ballot for the general militia.
1831. Militiamen raised by ballot in accordance with Order in Council, 27th December 1830. This was the last occasion on which the ballot was put in force.

During the great French war the utility of the militia was most marked, and before passing on to its revival in 1852, after the lapse of nearly forty years, the following summary of its position in the early years of the 19th century in relation to the whole army may be stated:—The tendency of the Government was to use the general militia rather as an offensive force and the local militia as the real defensive force. During the height of the war (in 1812) the relative position of the various branches of the army was as follows:—First line, the standing army; second line, the general or regular militia, which as the war went on were more and more used abroad; third line, the local militia, with the survivors of the volunteers, who at that time numbered about 68,000 men. After the peace of 1815 the militia was allowed practically to fall into abeyance, although the permanent staff was maintained. In 1848 the Prime Minister intimated in Parliament his intention to re-establish the militia, but it was not until 1852, after an unsuccessful attempt to resuscitate the local militia, that the general militia of England was reorganized under a system of voluntary enlistment with the ballot in reserve, Scotland and Ireland being included in 1854. The property qualification of officers which had hitherto existed (with exception in favour of ex-officers of the army and navy) was reduced, and after a further reduction in 1854, abolished in 1869. Larger powers respecting the militia were conferred upon the Crown, and during the Crimean war the Queen was authorized to embody the militia whenever a state of war existed with any foreign Power. The acceptance of voluntary offers of service in the Channel Islands and Isle of Man was authorized in 1859, and extended to service in Malta and Gibraltar in 1875. Previously service abroad was only temporarily authorized under certain restrictions, *e.g.*, in 1813, 1855, and 1858. Later enactments will be referred to in their proper place.

In 1871 the militia was brought more into touch with the regular army, and in 1881 became, with the line, battalions of territorial regiments, the artillery and engineers being also closely associated with the regular services. Various amendments and new enactments followed, all in the direction of increasing the usefulness of the militia, render-

ing it more efficient and readier for service, and making it more and more a means for supplying recruits, both officers and men, to the regular army. The present position of the force is as follows:—The officers who are commissioned by the Crown are, with the permanent staff, at all times (since 1877) subject to military law. Non-commissioned officers and men are only so subject when embodied or out for training, with extension in the case of men convicted of offences committed during training until the expiration of the punishment. Enlistment is at present voluntary, though compulsory service by ballot is still legal and may be at any time enforced. The minimum age for recruits is 17. Boys from 14 to 16 may be specially enlisted for buglers, drummers, or trumpeters. The period of engagement is for six years. Militiamen up to 45 years of age may re-engage for a further term of four years. Bounties are paid to militiamen at various rates upon enlistment, conclusion of training, re-engagement, enlistment into reserve or special service section, and other special circumstances. Recruit training may be extended to six months, but as a rule will not exceed three months. Recruits are either drilled immediately upon enlistment at any time of the year, which is now the most usual system, or else at preliminary drills (first instituted in 1860), immediately preceding the annual training of the corps. The annual training varies with the different branches of the service and certain special circumstances, but must not exceed 56 days. The usual term for infantry is 27 days, but when on manoeuvres this is generally extended to 34 days. Artillery and fortress engineers are trained for 41 days, and submarine mining engineers for 55 days. Trainings now take place for the most part in camp or barracks, and large numbers of militia battalions during recent years have been called upon to take part in field manoeuvres. Each branch of the militia service is now incorporated with the corresponding branch of the regular army, the depôts occupy as a rule the same barracks, and officers and men wear (with slight distinctions) the same uniform as the regulars. The militia occupies an important position in the mobilization scheme for national defence. The permanent staff consists of an adjutant, quartermaster, and an establishment of non-commissioned officers, and buglers or drummers, who are all regulars. During the non-training period of the year they are engaged in recruiting, care of arms, clothing, &c., and in drilling recruits. When the militia is embodied or called out for training they are incorporated with their units for executive as well as administrative duties.

The militia ordinarily is liable only for service in the United Kingdom, but by legislation in 1899 may voluntarily serve in any part of the world, including India. During 1899-1900, 22,000 militiamen were thus accepted for service abroad, the bulk of them proceeding to the seat of war in South Africa. The militia may be embodied in case of imminent national danger or great emergency. The procedure is by proclamation of the sovereign, the occasion being communicated to Parliament if sitting, but if not in session, Parliament must be called together within ten days. The militia has been constantly embodied since the reorganization in 1757 as follows:—1756-63, Seven Years' War; 1778-83, American War; 1792-1802, threatened invasions and Irish Rebellion; 1803-16, war with France; 1854-56, Crimean War, when several battalions served in Mediterranean garrisons; 1857-59, Indian Mutiny; 1885, Sudan Campaign; 1899-1902, South African War, when the whole militia force was embodied, and a large number of units of all branches volunteered for foreign service. The militia reserve consists of men selected from the ranks of the militia for special enlistment for service in the regular army when called upon in emergencies, in the following proportions to the establishments of the various corps:—Artillery, one-third; engineers and infantry, one-fourth; medical staff corps, one-half. Special regulations are made as to age, physique, and character. The militia reserve was first formed in 1867, and in 1900 numbered 30,000 men. During an emergency in 1878, 20,000 militia reservists joined the regular army. The term "militia" reserve is therefore a complete misnomer, and the force so called is purely an army reserve. The special service section of the militia was formed by royal warrant in 1898, and consists of (1) militia units and (2) individual militiamen. A militia unit may be registered as available for special service if not less than 75 per cent. of the officers and men present at training make a voluntary offer to engage for special service in any part of the world, and if in the infantry at least 500 and in the artillery at least 250 men are accepted as qualified. Individual militiamen are those who engage to serve either with their militia unit if registered for service, or else for special service with the regular forces. Liability for service will not exceed twelve months. They will not be called out except for service out of the United Kingdom; age 20 to 34; physical requirements as for regular army. Men of the special service section may also belong to the militia reserve, and receive a bounty in addition to that given for the reserve. The result of this special section was not up to 1900 so satisfactory as expected. Very few units could qualify for registration, and the response of individual men was comparatively insignificant.

“CHRIST IN THE HOUSE OF HIS PARENTS.” BY SIR JOHN EVERETT MILLAIS.

There is no fixed quota for the militia under present enactments; the numbers vary from year to year, as voted by Parliament. The following figures (showing the state of affairs previous to the Boer war of 1899) relate to the year 1898. The total establishment for the United Kingdom numbered 132,493, divided between England, 87,828; Scotland, 15,695; Ireland, 28,970. Subdivided among the different branches these numbers represented 18,520 artillery, 2060 engineers, 111,300 infantry, and 613 medical staff. The total number actually enrolled was 113,439, thus showing a deficiency of 19,054, made up of 649 officers, 77 permanent staff, and 18,328 non-commissioned officers and men. England was responsible for 14,169 of this deficiency, Scotland for 2011, and Ireland for 2874. Of the total number enrolled (113,439), England provided 73,659; Scotland, 13,684; and Ireland, 26,096. Shown by arms, the artillery mustered 16,886; the engineers, 2098; infantry, 94,114; and medical staff, 341. The religious denominations of the non-commissioned officers and men were thus returned:—Church of England, 53,610; Roman Catholic, 40,496; Presbyterians, 8668; Wesleyans, 3624; other Protestants, 1309; Jews, 46. 40,127 recruits joined the militia during 1898. Of these approximately one-half were 18 years of age and under. 2905 men re-enlisted or rejoined after desertion. The total increase was shown as 43,013. The total decrease from all causes was 44,897 men, of whom 19,808 were discharged, 383 were reported to have died, and 8743 were struck off for desertion or other causes. 15,167 men were transferred to the regular army, and 796 to the Royal Navy and marines. Militia recruiting for the regulars thus shows a large increase compared with preceding years. The net decrease was 1884 men. "Crime" in the militia was represented by 996 offences of the usual military character, which were dealt with by 846 courts-martial. Of these offences, 489 were for absence without leave. None of the others were of a serious nature. 2726 men were fined for drunkenness. 8718 men deserted, of whom nearly half had less than one year's service. 98,042 militiamen were present at annual training; 7240 were absent with leave, 8157 without leave. England produced 63,048 men for training, Scotland 11,520, and Ireland 23,474. These numbers together represented 14,734 artillery, 1864 engineers, 81,161 infantry, and 283 medical staff corps. The ages of the majority of militiamen range from 17 to 35 years. 782 were under 17, and 14,611 over 35 years of age. The heights of the majority of the men range from 5 feet 4 inches to 6 feet. 8997 men were under 5 feet 4 inches, and 909 were over 6 feet in height. A larger number of men approximated to 5 feet 6 inches than to any other height. In the House of Lords, on Friday the 25th May 1900, the marquis of Lansdowne, Secretary of State for War, stated that the grand total of the militia on the 1st May was 99,000 men. Of these 22,000 were abroad, 11,000 belonged (*i.e.*, called up for service with regulars) to the militia reserve, leaving 66,000 militia at home. These figures, presumably correct, thus show a further decrease of 14,000 men since the returns of 1898. On the other hand, Lord Lansdowne was able to announce that a deficiency of 649 officers in 1898 had by the war been turned into an excess of 20 officers above the establishment. The militia in recent years had steadily decreased. In 1881, the year when the militia was practically incorporated with the regular army, there were 127,868 militia of all ranks actually enrolled, and 11,633 wanting to complete. Thus it appears that up to 1898 there had been a loss of 14,429 men, and with the further loss of 14,000 noted above as officially stated in Parliament, the total decrease in the militia in nineteen years was upwards of 28,000 men. This steady depletion of the militia has a most serious bearing upon the military strength of Great Britain.

(A. B. W.)

Millais, Sir John Everett (1829–1896), English painter, was born at Southampton on the 8th June 1829, the son of John William Millais, who belonged to an old Norman family settled in Jersey for many generations, and Emily Mary, *née* Evamy, the widow of a Mr Hodgkinson. After his birth the family returned to Jersey, where the boy soon began to sketch. At the age of eight he drew his maternal grandfather. He went to school for a short time, but showed no inclination for study, and was afterwards educated entirely by his mother. In 1835 the family removed to Dinan in Brittany, where he sketched the French officers, to their great amusement, and in 1837, on the family's return to Jersey, he was taught drawing by a Mr Bissel. In 1838 he came to London, and, on the strong recommendation of Sir Martin Archer Shee, P.R.A., his future was decided. He was sent at once to Sass's school, and entered the Academy schools in

1840. He won a silver medal from the Society of Arts in 1839, and carried off all the prizes at the Royal Academy. He was popular amongst the students, and was called "the child," because he wore his boyish costume till long after the usual age. In 1840 and the immediately succeeding years he made the acquaintance of Wordsworth and other interesting and useful people. He was at this time painting small pictures, &c., for a dealer named Thomas, and defraying a great part of the household expenses in Gower Street, where his family lived. In 1846 he exhibited "Pizarro seizing the Inca of Peru" at the Royal Academy, and in 1847 "Elgiva seized by the Soldiers of Odo." In the latter year he competed unsuccessfully at the exhibition of designs for the decoration of the Houses of Parliament, sending a very large picture of "The Widow's Mite," which was afterwards cut up. In the beginning of 1848 he and W. Holman Hunt, dissatisfied with the theory and practice of British art, which had sunk to its lowest and most conventional level, initiated what is known as the Pre-Raphaelite movement, and were joined by Dante Gabriel Rossetti, and afterwards by five others, altogether forming the Pre-Raphaelite Brotherhood. Rossetti was then engaged, under the technical guidance of Hunt, upon his picture of "The Girlhood of Mary Virgin," which, with Hunt's "Light of the World" and Millais's "Christ in the House of His Parents," forms what has been called the trilogy of Pre-Raphaelite art. According to Millais, the Pre-Raphaelites had but one idea—"to present on canvas what they saw in Nature." Millais's first picture on his new principles was a banquet scene from Keats's "Isabella" (1849), and contains all the characteristics of Pre-Raphaelite work, including minute imitation of nature down to the smallest detail, and the study of all persons and objects directly from the originals. The tale was told with dramatic force, and the expression of most of the heads was excellent. His next important picture, "Christ in the House of His Parents," or "The Carpenter's Shop" (1850), represented a supposed incident in the childhood of our Lord treated in a simply realistic manner, and drew down upon him a storm of abuse from nearly all quarters, religious and artistic. The rest of his more strictly Pre-Raphaelite pictures—"The Return of the Dove to the Ark," "The Woodman's Daughter," and the "Mariana" of 1851, "The Huguenot" and "Ophelia" of 1852, "The Prescribed Royalist" and "The Order of Release" of 1853—met with less opposition, and established his reputation with the public. Indeed, this may be said to have been accomplished by the "Huguenot" and "Ophelia," the refined sentiment and exquisite execution of which appealed to nearly all who were unprejudiced. The public were also greatly influenced by the splendid championship of Ruskin, who, in letters to *The Times*, and in a pamphlet called "Pre-Raphaelitism," enthusiastically espoused the cause of the Brotherhood. In 1851 Millais, who had refused to read *Modern Painters*, where the supposed principles of the Brotherhood were first recommended, became acquainted with Ruskin, and in 1853 went to Scotland with him and Mrs Ruskin, the latter of whom sat for the woman in "The Order of Release." He made several designs for Ruskin, and painted his portrait. In 1855 Millais exhibited "The Rescue," a scene from a fire, which drew great attention, from the frantic expression of the mother and the brilliant painting of the glare. In the Paris Exhibition of this year he was represented by "The Order of Release," "Ophelia," and "The Return of the Dove." This was also the year of his marriage with Mrs Ruskin (Euphemia Chalmers, daughter of Mr George Gray of Bowerswell, Perth), who had obtained a decree of the nullity of her previous marriage. The newly-wedded couple went to live at Annat Lodge, near Bowerswell, where

"Autumn Leaves," described by Ruskin as "the first instance of a perfect twilight," was painted. This and "Peace Concluded" were singled out for special praise by Ruskin in his notes on the Academy Exhibition of 1856, which contained, with other works by Millais, the picture of "A Blind Girl," with a beautiful background of Icklesham and its common. The principal pictures of 1857 were "Sir Isumbras at the Ford," and "The Escape of a Heretic," both of which were violently attacked by Ruskin, who was kinder to the "Apple-blossoms" and "Vale of Rest" of 1859, extolling the power of their painting, but still insisting on the degeneracy of the artist. The "Black Brunswicker" of 1860 was in motive very like the "Huguenot," but it was less refined in expression, and a great deal broader in execution, and may be said to mark the end of the period of transition from his minute Pre-Raphaelite manner to the masterly freedom of his mature style. From 1860 to 1869 the invention of Millais was much employed in illustration, especially of Trollope's novels, beginning with *Framley Parsonage* in the *Cornhill Magazine*. He made altogether eighty-seven drawings for Trollope, and was the cleverest and one of the most prolific of the book illustrators of the 'sixties. He contributed to Moxon's illustrated edition of *Tennyson's Poems*, and made occasional drawings for *Once a Week*, the *Illustrated London News*, *Good Words*, and other periodicals and books. In 1863 he was elected a Royal Academician. The most important pictures of this and the next few years were "The Eve of St Agnes," remarkable for the painting of moonlight, "Romans leaving Britain" (1865), "Jephthah" (1867), "Rosalind and Celia" (1868), "A Flood," and "The Boyhood of Raleigh" (1870). All these were executed in a

very broad and masterly manner. In many of his pictures of this period, such as "The Boyhood of Raleigh," his children were his models, and formed the subject of many more, like "My First Sermon," "My Second Sermon," "Sleeping," "Awake," "Sisters," "The First Minuet," and "The Wolf's Den." He now painted many single figures with more or less sentiment, like "Stella," "Vanessa," and "The Gambler's Wife," with occasionally a more important composition, like "Pilgrims to St Paul's," and "Victory, O Lord" (exhibited 1871), representing Aaron and Hur holding up Moses' hands (Exodus xvii. 12). With it was exhibited the first and most popular of his pure landscapes, called "Chill October," which was followed at intervals by several others remarkable for literal truth to nature and fine execution. They were all from Perthshire, where he generally spent the autumn, and included "Scotch Firs" and "Winter Fuel" (painted in 1874), "Over the Hills and Far Away," and "The Fringe of the Moor" (1875), and "The Sound of Many Waters" (1876). A later series was painted in the neighbourhood of Murthly, a village

in the parish of Little Dunkeld, Perthshire, where he rented a house and shooting from 1881 to 1891. It was to painting nature and the world around him that he principally devoted himself for the last twenty-five years of his life, abandoning imaginative or didactic themes. To this period belong a number of pictures of children, with fancy titles, like "Cherry Ripe," "Little Miss Muffet," "Bubbles," and others well known by reproductions in black and white and in colour for the illustrated papers; and also some charming studies of girlhood, like "Sweetest eyes were ever seen," and "Cinderella." Amongst his more serious pictures were "The Princes in the Tower" (1878), "The Princess Elizabeth" (1879), two pictures from Scott—"Effie Deans" and "The Master of Ravenswood"—painted for

Messrs Agnew in 1877 and 1878, and "The North-West Passage," sometimes regarded as his masterpiece, representing an old mariner (painted from Edward John Trelawney, the friend of Byron) listening to some tale of Arctic exploration in a room overlooking the sea and strewn with charts. "A Yeoman of the Guard" (1877) was perhaps his most splendid piece of colour, and was greatly admired at the Paris Exhibition of 1878, where it was sent with "Chill October" and three others of his pictures. But perhaps the works of his later years by which he will be most remembered are his portraits—especially his three portraits of Gladstone (1879, 1885, and 1890), and those of John Bright, of Lord Tennyson, and of Lord Beaconsfield, which was left unfinished at his death. He also painted the marquess of Salisbury, Lord Rosebery, the dukes of Devonshire and Argyll, Cardinal Newman, Thomas Carlyle, Sir James Paget, Sir Henry Irving, George Grote, Lord

SIR JOHN EVERETT MILLAIS.
(From a photograph by Elliott and Fry, London.)

Chief Justice Russell, J. C. Hook, R.A., and himself (Uffizi Gallery, Florence). He drew Charles Dickens after his death. Amongst his finer portraits of women were those of Mrs Bischoffsheim, the duchess of Westminster, Lady Campbell, and Mrs Jopling.

No very serious interruption of his usual life as a prosperous English gentleman occurred in these years, except the death of his second son George in 1878. In 1875 he went to Holland, one of his few visits to the Continent. In 1879 he left Cromwell Place for a house at Palace Gate, Kensington, which he built, and where he died. In 1885 he was created a baronet on the suggestion of Mr Gladstone. In 1892 his health began to break down. After a bad attack of influenza he was troubled with a swelling in his throat, which proved to be due to cancer. He suffered much from depression, but worked when he could, and derived much pleasure in painting several pictures, including "St Stephen," "A Disciple," "Speak! Speak!" (which was bought out of the Chantrey Bequest), and "The Forerunner"—his last exhibited

subject picture. His finely-characterized portraits of Mr John Hare, the actor, and Sir Richard Quain, belong also to his last years. In 1895, in consequence of the illness of Lord (then Sir Frederick) Leighton, he was called upon to preside at the annual banquet of the Royal Academy, and on the death of Lord Leighton he was elected to the presidential chair. He died on the 13th August 1896, and was buried in St Paul's Cathedral. The Winter Exhibition of the Royal Academy in 1898 was devoted to his works. The list of his honours at home and abroad is a long one. Millais was one of the greatest painters of his time, and did more than any other to infuse a new and healthy life into British art. He had not the imagination of an idealist, but he could paint what he saw with a force which has seldom been excelled. As a man he was manly, frank, and genial, devoted to his art and his family, and very fond of sport, especially hunting, fishing, and shooting. He was greatly loved by a very large circle of friends. He was singularly handsome, and had a fine presence. The National Gallery of British Art possesses many of his finest works. He is also represented in the National Gallery, in the National Portrait Gallery, the Victoria and Albert Museum, and in the public galleries at Manchester, Liverpool, and Birmingham.

Millbury, a town of Worcester county, Massachusetts, U.S.A., a few miles south of the city of Worcester. It is traversed by the Boston and Albany and the New York, New Haven, and Hartford railways. It has an area of 17 square miles, composed of hills and valleys, with many small lakes and ponds. The village of Millbury has an irregular plan, and contains many small manufacturing establishments with varied products. The town was separated from Sutton and incorporated in 1813. Population (1890), 4428; (1900), 4460, of whom 1176 were foreign-born.

Milledgeville, a city of Georgia, U.S.A., capital of Baldwin county, on the west bank of the Oconee river, at the head of navigation, and on the Georgia and the Central of Georgia railways, a little north-east of the centre of the state, at an altitude of 276 feet. It is the seat of several educational institutions, and of the state lunatic asylum. It was formerly the state capital. Population (1890), 3322; (1900), 4219, of whom 29 were foreign-born and 2663 were negroes.

Miller, Joaquin [CINCINNATUS HINER] (1841—), American poet, was born in Indiana, 10th November 1841, and was educated for the law. After some experiences of mining and journalism in Idaho and Oregon, he settled down in 1866 as judge in Grant county, Oregon, and during his four years' tenure of this post he began to write verse. In 1870 he travelled in Europe, and in 1871 he published his first volume of poetry, full of tropical passion, *Songs of the Sierras*, on which his reputation mainly rests. His *Songs of the Sunlands* (1873) followed in the same vein, and after other volumes had appeared, his *Collected Poems* were published in 1882. He also wrote plays, *The Danites* having some success as a sensational melodrama. On his return from Europe he became a journalist in Washington, but in 1887 returned to California. His pen-name, "Joaquin Miller," by which he is known, was assumed by him when he published his first book, in consequence of his having written an article in defence of Joaquin Murieta, the Mexican brigand.

Milligan, William (1821–1892), Scottish commentator and theologian, was born 15th March 1821, and commenced his education at the High School, Edinburgh. When his father was appointed to the charge of the parish of Elie, in Fifeshire, he went to a parish school in the neighbourhood, and proceeded to the University of St Andrews at the age of fourteen. His college career was distinguished, and he graduated in 1839. His divinity studies were carried on partly at St Andrews and partly in Edinburgh. In 1844, a year after the Disruption, he became minister of Cameron in Fifeshire. In 1845, his health having given way, he went to Germany, and studied at the university of Halle. There he became acquainted with the German language and German theology, a fact which greatly influenced his later career. He began, after his return to Scotland and his resumption of his clerical duties, to write articles on Biblical and critical subjects for various reviews. This led to his appointment in 1860 to the professorship of Biblical criticism in the University of Aberdeen. In 1865 he acquired the Syriac tongue. In 1870 he was appointed one of the committee for the revision of the translation of the New Testament. His fervent piety, and his wide interest in educational and social questions, extended his influence far beyond the circle of theologians. His contributions to periodical literature for many years were numerous and valuable; but his celebrity will chiefly rest on his works on the *Resurrection* (1890) and *Ascension of our Lord* (1892), his Baird Lectures (1886), on the *Revelation of St John*, and his *Discussions* (1893) on that book. All these volumes are distinguished by great learning and acuteness, as well as by breadth and originality of view. He died on 11th December 1892. (J. J. L*.)

Millom, a market town in the Egremont parliamentary division of Cumberland, England, 9 miles north by west of Barrow, on the Furness railway. There are blast furnaces and highly productive mines of red hæmatite ore. The deposit lies partly under the foreshore of the river Duddon, and a company has expended upwards of £120,000 upon a sea-wall and embankment to protect the mine from the sea. St Luke's Church (1891), a Baptist chapel and Salvation Army station, are new. Population (1891), 8895; (1901), 10,426.

Millville, a city of Cumberland county, New Jersey, U.S.A., on the Maurice river and on the West Jersey and Seashore railroad, in the southern part of the state, at an altitude of 36 feet. Its site is level and its street plan is regular. It has manufactures of glass, iron, and cotton. Population (1890), 10,002; (1900), 10,583, of whom 598 were foreign-born and 139 were negroes.

Milne-Edwards, Henry (1800–1885), French zoologist, the son of an Englishman, was born in Bruges on 23rd October 1800, but spent most of his life in France. At first he turned his attention to medicine, in which he graduated at Paris in 1823; but his passion for natural history soon prevailed, and he gave himself up to the study of the lower forms of animal life. One of his earliest papers (*Recherches anatomiques sur les Crustacés*), which was presented to the Academy of Sciences in 1829, formed the theme of an elaborate and eulogistic report by Cuvier in the following year. It embodied the results of two dredging expeditions undertaken by him and his friend Andouin during 1826 and 1828, in the neighbourhood of Granville, and was remarkable for clearly distinguishing the marine fauna of that portion of the French coast into four zones. Much of his original work was published in the *Annales des Sciences Naturelles*, with the editorship of

which he was associated from 1834. Of his books may be mentioned the *Histoire naturelle de Crustacés* (3 vols., 1837-41), which long remained a standard work; *Histoire naturelle des Coralliaires*, published in 1858-60, but begun many years before; *Leçons sur la physiologie et l'anatomie comparée de l'Homme et des Animaux* (1857-1881), in 14 volumes; and a little work on the elements of zoology, originally published in 1834, but subsequently remodelled, which enjoyed an enormous circulation. He was appointed professor of natural history at the Faculté des Sciences in 1841, and twenty-one years later became professor of zoology at the Museum, where in 1876 he was succeeded by his son Alphonse (b. 1835). The Royal Society in 1856 awarded him the Copley medal in recognition of his zoological investigations. He died in Paris on 29th July 1885.

Milngavie, a police burgh of Dumbartonshire, Scotland, transferred from Stirlingshire in 1891, lies 9½ miles north-west of Glasgow by rail. There are bleach-fields, dyeworks, and a paper mill; but the town is rapidly becoming residential for Glasgow business men. Adjacent are two water reservoirs, 60 and 90 acres in extent, belonging to the corporation of Glasgow. There is a burgh hall. Population (1881), 2636; (1901), 3481.

Milton, a town of Norfolk county, Massachusetts, U.S.A., a few miles south of Boston, of which it is practically a suburb, on a branch of the New York, New Haven, and Hartford railroad, in the eastern part of the state. It contains an area of 18 square miles of rolling and hilly country, in which are the villages of Milton, Milton Lower Mills, East Milton, and Milton Upper Mills. It contains the Blue Hills, now a part of the Boston park system, on one of which is situated a meteorological observatory. The town was settled in 1640 and incorporated in 1662. Population (1890), 4278; (1900), 6578, of whom 1840 were foreign-born.

Milton, a borough of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river, on the Pennsylvania canal, and on the Pennsylvania and the Philadelphia and Reading railways, a little east of the central part of the state, at an altitude of 472 feet. It contains car works, rolling mills, and other iron and steel works. It was founded in 1797, and chartered twenty years later. In 1882 it was in great part destroyed by fire. Population (1890), 5317; (1900), 6175, of whom 168 were foreign-born and 97 were negroes.

Milwaukee, the largest and most important city of Wisconsin, U.S.A., capital of Milwaukee county, on the western shore of Lake Michigan, at the mouth of the Milwaukee river, in the south-eastern part of the state. It is regularly laid out, with broad streets, paved mainly with wooden blocks. Its water-supply is derived from Lake Michigan, and it has an excellent sewer system. Among its newer buildings of note are the Federal Building (housing the Post Office, Custom House, &c.), Court House, City Hall, the Chamber of Commerce, and the Public Library (containing 100,000 volumes). Milwaukee is a lake port of the first importance, having an excellent harbour, improved by breakwaters. Most of its commerce is domestic, and consists mainly of grain and lumber. It is also a large railway centre, being entered by four railways—the Chicago and North-Western, the Chicago, Milwaukee and St Paul, the Pere Marquette, and the Wisconsin Central, giving it a large inland traffic. As a manufacturing city Milwaukee is of great importance. In 1900 it contained 3342 manufacturing establishments, with a total capital of \$110,363,854. They employed 48,328 hands (exclusive of 4352 salaried officials, clerks,

&c.), to whom was paid in wages \$20,240,656. The value of materials used was \$65,118,719, and that of the products was \$123,786,449. The principal of these products, with their values, were as follows:—flouring and grist-mill products, \$6,357,983; foundry and machine-shop products, \$14,495,362; iron and steel, \$7,410,213; leather (tanned, curried, and finished), \$10,267,835; malt liquors, \$13,899,390; slaughtering and meat-packing (wholesale), \$5,980,340. The city is noted for its extensive breweries, the products of which are distributed to all parts of the country. The assessed valuation of real and personal property in 1900, on a basis of about 60 per cent. of the full value, was \$158,174,873; the net debt was \$6,576,586, and the average rate of taxation was \$23.14 per \$1000. The actual income of the city for the fiscal year, exclusive of loans, was \$4,349,065, and the expenditures, exclusive of loans repaid, were \$4,313,889. Population (1880), 115,587; (1890), 204,468; (1900), 285,315, showing a very rapid growth. Of the total population in 1900, 98,991 were foreign-born (principally Germans) and 862 were negroes. There were 98,802 persons of school age (5 to 20 years inclusive). Out of a total of 75,020 adult males, 34,535 were native-born (of whom only 163 were illiterate, *i.e.*, could not write), and 40,485 were foreign-born (of whom 2896 were illiterate). The death-rate in 1900 was 15.9; in 1890 it was 18.8.

Minas Ceraes, a state of Brazil, situated between 13° 55' and 23° S. and 39° 37' and 50° 58' W., bounded on the N. by the state of Bahia, on the W. by Goyaz, Matto Grosso, and Sao Paulo, on the S. by Sao Paulo and Rio de Janeiro, and on the E. by Espirito Santo and Rio de Janeiro. Its area is 222,160 square miles, and it has the largest population, about 3¼ millions, of any state in Brazil. The capital, Ouro Preto, has a population of over 20,000. Amongst other towns are Diamantina (13,000), Entre Rios (8500), Marianna, Earbacena, Abaeté, Bambuhy, Curvello, &c. The state is well provided with railways, and its mines and agricultural products are rich and varied.

Minbu, a division and district in Upper Burma. The division includes the districts of Thayetmyo, Pakòkku, Minbu, and Magwe. It has a total area of 17,170 square miles, and a population (1891) of 996,873, and (1901) 1,077,978, showing an increase of 8 per cent., and giving a density of 63 inhabitants to the square mile, with 4095 villages paying in 1898-99 a revenue of Rs.23,28,599. It bestrides the Irrawaddy. The district of MINBU has an area of 3297 square miles, and population (1891) of 215,563, and (1901) 236,262, showing an increase of 9.6 per cent. and a density of 71 inhabitants to the square mile, with 1043 villages paying a revenue of Rs.5,99,866. As a whole the district may be said to consist of low plain land towards the Irrawaddy, and of undulating country inland rising higher and higher westwards towards the Arakan hills. Between the plain and the Yoma is a distinct range of hills running north and south, and usually called the Nwa-Madaung hills. The submontane valleys are largely cultivated, but are deadly except to those born in them. The chief streams besides the Irrawaddy are the Môn, the Man, and the Salin, which are largely used for irrigation purposes. At Minbu town the Irrawaddy is 3 miles wide, with numerous islands and sandbanks. There are considerable fisheries along the Irrawaddy and on the Paunglin lake, which is a lagoon fed from the Irrawaddy. The rights are sold yearly by public auction, and realize an average of Rs.15,000. Oil has been discovered near the mud volcanoes of Minbu, but it seems to lie at too great a depth to be profitably worked.

There are 185 square miles of reserved forest in the district. The great bulk of the population is agricultural, and the chief crops raised are paddy, gram, millet, beans, peas, sesamum, and tobacco. The betel-vine is largely cultivated along the Môn river. The district, which was in a chronically disturbed state before the annexation, was not reduced till two years afterwards, many officers losing their lives, among them Phayre, the first deputy-commissioner. The population of the district in 1891 was made up of 206,914 Buddhists, 6867 Chins, 956 Hindus, 691 Mahomedans, and 135 Christians. 173,408 acres were cultivated in 1898-99, and 463,000 acres were available for cultivation; 362,827 acres of current fallow existed, and there were 229,120 acres of forest land, besides 881,771 not cultivable. The annual rainfall varies greatly over the district. It is very considerable on and under the Arakan Yoma, and very slight towards the Irrawaddy. The total in 1898-99 at Minbu was 25.66 inches. The thermometer rises to over 100° in the hot months, and the mean of minimum readings in December is usually about 49°. MINBU, the district headquarters, stands on the Irrawaddy. It had a population of 6270 in 1891. A bank has formed in front of the town, so that the river steamers in the dry season can come no nearer than two miles to the south of the town. (J. G. Sc.)

Minden, a town and episcopal see of Prussia, province of Westphalia, on the river Weser, 40 miles west-south-west of Hanover by railway. The churches of St Mary and St Simeon, the synagogue (1864), the post office (1895), the war memorials of 1864-66 and 1870-71, and the classical school (with two large paintings by Thumann) should be mentioned. Population (1885), 18,592; (1900), 24,327.

Minehead, a market town and seaside watering-place of Somersetshire, England, on the Bristol Channel, with a station (branch terminus) on the Great Western railway. It has a tidal harbour and a quay. Minehead is the point of departure for the coaches to Porlock and Lynton. Population, about 3000.

Mineo, a town of the province of Catania, Sicily, Italy, with a station (4 miles distant) on the branch line from Catania (35 miles) to Caltagirone. The ancient *Mence*, laid out by the Sicilian chief Ducetius, a native of the town, in the middle of the 5th century B.C., it was captured by the Saracens in 840. Four miles to the north is Lake Palici, with strong outflow of carbonic acid, a place of great sanctity and veneration to the ancients, who had there a widely famous temple to the "Palician gods." Population, about 9000.

Minghetti, Marco (1818-1886), Italian patriot and statesman, was born at Bologna on 18th November 1818. In 1846 he signed the petition to the Conclave for the election of a Liberal pope, and was appointed member of the State Council summoned to prepare the constitution for the papal states. In the first constitutional cabinet, presided over by Cardinal Antonelli, Minghetti held the portfolio of public works, but after the allocution pronounced by Pius IX. against the Italian war of independence he resigned office and joined the Piedmontese army with the rank of major. Returning to Rome in September 1848, he refused to form a cabinet after the assassination of Pellegrino Rossi, and, withdrawing from political life, spent the next eight years in study and travel. Summoned to Paris by Cavour in 1856 to prepare the memorandum on the Romagna provinces for the Paris congress, he resumed his public labours for the cause of unity, and was in 1859 appointed by Cavour secretary-general of the Italian Foreign Office. In the same year he was elected president of the assembly of the Romagna after the rejection of pontifical rule by those provinces, and prepared their annexation to Piedmont. Appointed Piedmontese minister of the interior, he resigned office shortly after Cavour's death, but was subsequently chosen to be minister of finance by Farini, whom he succeeded as premier in 1863. With the help of Visconti Venosta he concluded (15th September 1864) a convention with

France known as the "September Convention," whereby Napoleon agreed to evacuate Rome and Italy to transfer her capital from Turin to Florence. The convention excited violent opposition and sanguinary disorders at Turin, in consequence of which Minghetti was obliged to resign office. An object of hatred and unjust accusations, he took little part in public life until 1869, when he accepted the portfolio of agriculture in the Menabrea Cabinet. Both in and out of office he exercised his influence against the scheme of an Italo-French alliance and in favour of an immediate advance upon Rome, and in 1870 was sent to London and Vienna by the Lanza-Sella Cabinet to organize a league of neutral powers in consequence of the outbreak of the Franco-Prussian war. In 1873 he overthrew the Lanza-Sella Cabinet and regained the premiership, which, with the portfolio of finance, he held until the fall of the Right from power on 18th March 1876. During his premiership he inaugurated the *rapprochement* between Italy, Austria, and Germany, and before his fall was able, as finance minister, to announce the restoration of equilibrium between expenditure and revenue for the first time since 1860. After the advent of the Left, Minghetti remained for some years in Opposition, but, towards 1884, joined Depretis in creating the parliamentary phenomenon known as "Transformism," which consisted in bringing Conservative support to Liberal cabinets. Minghetti, however, drew from it no personal advantage, and died at Rome on 10th December 1886 without having returned to power. (H. W. S.)

Miniatures.—The word miniature is derived from *minium*, signifying red lead, in consequence of the capital letters, borders around pages, and headings to chapters in ancient manuscripts having been drawn in this material; it was applied originally to the decorations on the pages of such manuscripts. These illuminations were at first executed in red alone, and afterwards in various colours, when later on they took the form of elaborate designs, embracing pictures of saints, portraits of persons, and illustrations of stories and legends, with religious emblems and medallions. By a further development the word came to be applied to such pictures or portraits as were similar in size to these small illuminations on MSS. It is believed that this use of the word came into vogue in the early part of the 18th century, and was applied to such paintings as before then had commonly been called either "limnings" (see the catalogue of the pictures belonging to Charles I.) or else "paintings in little" (see *Pepys' Diary*, 30th March 1668, &c.). The word is now used mainly in this sense, and by a miniature is meant a painting on a very small scale, usually a portrait, painted on ivory, card, or metal, of such a size as can be carried in the pocket.

In Europe the art of painting in miniature is to a great degree distinctively English, and the greater number of the chief masters in the art have been Englishmen or at least have lived in England. Several of the great portrait painters are said to have worked occasionally in miniature, and there are paintings, small in size, which are attributed with reason to Holbein, Antonio More, "Shootes and Betts" (see Lomazzo's *Trattato dell' Arte della Pittura*, Oxford, 1598), Cleef, Stretes, Teerlinck, Zucchero, John and T. Betts, and with less probability even to Van Dyck. The first true miniaturist, however, was Nicholas Hilliard (*circa* 1547-1619), whose work partakes of the character of that seen in illuminated manuscripts. The colours are opaque, gold is used to heighten the brilliant effect, and the paintings are on card. They are often signed, and have frequently also a Latin motto upon them.

Isaac and Peter Oliver (father and son) succeeded Hilliard. Isaac (*circa* 1551-1617) is said to have been

the pupil of Hilliard and of Zuccherò. Peter (died 1647) was the pupil of Isaac. The two men were the earliest to give roundness and form to the faces they painted, leaving for ever the flat method of the illuminators. They signed their best works by a monogram, and painted not only very small miniatures, but larger ones measuring as much as 10 inches by 9. They copied for Charles I. on a minute scale many of his famous pictures by the old masters. Several of these copies are at Windsor and Montagu House. At about the same date Gerbier, Poel-emberg, Jamesone, Penelope Cleyn, and her brothers, were workers in the art. John Hoskins (died 1664) was a far better artist in miniature than those just named, but his greatest claim to recollection consists in his having been the master of Samuel Cooper, the greatest English miniaturist. The work of Hoskins can be specially well studied in the collection at Ham House.

Samuel Cooper (1609-1672) was a nephew of Hoskins. He spent much of his time in Paris and Holland, and very little is known of his career. His work has a superb breadth and dignity. It has been well if paradoxically called "life-size work in little"; and the portraits which he painted of the men of the Puritan epoch are remarkable for their extraordinary merit, for truth to life, and for strength of handling and presentment. He painted upon card, chicken-skin (*pecorella*), or vellum, and on rare occasions upon rough bone. The use of ivory was not introduced until after his time. His work is frequently signed with his initials, generally in gold, and often in the hair of the person depicted. Flatman (died 1688), Alexander Cooper, brother of Samuel Cooper, David Loggan, White, Sadler, Digby, and Faber deserve notice at this period; and they were followed by such artists as Lawrence Crosse (died 1724), Gervase Spencer (died 1763), Lens, Hone, and Meyer, the latter two of whom were notable in connexion with the foundation of the Royal Academy.

The 18th century produced a great number of miniature painters, of whom Richard Cosway (*circa* 1742-1821) is the most famous. His works are of great beauty, and are done with a dash and brilliance which no other artist excelled. The leading miniaturist of his time, Cosway was especially popular in the circle of the Prince Regent. His best work was done about 1799. It is always on ivory, although he also did what were called "stayed drawings." These were drawn in pencil on paper, with the faces coloured. Cosway's finest paintings are signed on the back with a specially pompous signature; there is known but one genuine Cosway miniature which is signed on its face; very few bear even his initials on the front. George Engleheart (1750-1829) was his great rival, and was attached to the court of the king. He painted 4900 miniatures, and his work is stronger and more impressive than that of Cosway; it is often signed "E." or "G. E." Andrew Plimer (1763-1837) was a pupil of Cosway, and both he and his brother Nathaniel, who worked in the same studio, produced some lovely portraits. The brightness of the eyes, wiriness of the hair, and exuberance of colour, combined, however, with drawing which is often very inaccurate, are characteristics of Andrew Plimer's work.

John Smart (1741-1811) was the greatest of Cosway's pupils. His work surpassed that of his master in refinement, power, and delicacy; its silky texture and elaborate finish, and the artist's love for a brown background, distinguish it. Other notable painters were Ozias Humphrey (1742-1810); Nixon (1741-1812); Shelley (*circa* 1750-1808), whose best pictures are groups of two or more persons; William Wood, a Suffolk artist (1768-1808); Edridge (1769-1821); Sullivan, Sheriff, Crosse, Boyle, and Finney. In the 19th century J. C. D. Engleheart (1784-1862; nephew of George), Andrew Robertson (1777-1845),

Beaumont, Behnes, Harlow, Heaphy, and Mrs Mee must be mentioned. Sir Thomas Lawrence painted miniatures, but the art may be said to have died out with Sir William Ross, the Chalons, and Newton (although some works by Landseer in this form are in existence). Towards the end of the 19th century there was an attempted revival; but although there have been many miniatures, there have hitherto been no masters. Of modern miniature painters, Alyn Williams best deserves mention.

Many fine miniatures were executed in enamel. Petitot (1607-1691) was the greatest worker in this material, and did his finest portraits in Paris for Louis XIV. His son succeeded him in the same profession. Other artists in enamel were Boit (died 1727), Zinke (died 1767), Hurter (1734-1790), Spicer, Thouron (1737-1789), Prieur, Dinglinger, and Thienpondt. Many of these artists were Swiss, but most of them visited England and worked for a while there. The greatest English enamel portrait painter was Henry Bone (1755-1834), the finest of whose productions are now at Kingston Lacy. A great collection of his small enamel reproductions of celebrated paintings is in Buckingham Palace.

Perhaps the earliest French miniature painter was Jean Clouet (died *circa* 1490), while of a much later date Blarenberghe (born 1719) and Drouais (1699-1767) should also be mentioned; but the most popular artists were Augustin (d. 1832) and Isabey (d. 1855). Their portraits of Napoleon and his court are exceedingly fine.

Hall the Swede and Fuger the Austrian were also great miniature painters; and others whose names might be mentioned were Werner (1637-1710), Rosalba Carriera (1675-1757), Chatillon, Pasquier, and Festa.

Miniatures are painted both in oil and in water colour, but by far the greater number are in water colour. A few of Cooper's works are in oil, and these are generally painted on copper. The work of the 18th century is exclusively in water colour. The use of ivory came into general adoption in the early part of the reign of William III., although there are extant miniatures even by Cooper which are painted on a sort of rough bone closely resembling ivory. The work of Snelling, David Loggan, and others was in pencil, used with great effect on vellum. The earliest miniatures are upon card, copper, vellum, or chicken-skin.

The greatest collections of miniatures in England are now (1902) those in the possession of the King, the duke of Buccleuch, the earls of Ilchester, Dysart, Dartrey (notable for enamel work, some examples of which are of the greatest rarity), and Ancaster (especially notable for works by Cosway); of Earl Beauchamp, the Baroness Burdett-Coutts, Sir Gardner Engleheart (notable for works by the Englehearts), Countess Tolstoy, and Messrs. Drake, Digby, J. Pierpont Morgan (noteworthy for the superb series of 18th century portraits and works by Cooper), Senior, E. W. Williams, Whitehead, and Usher of Lincoln. There are also very fine works by Cooper at South Kensington, and in the same gallery, in the Jones collection, some splendid works by Petitot; and there are some famous foreign portraits and picture-miniatures in the Wallace collection, Hertford House, London. The collection at the Louvre, especially as regards the works of Petitot, is of supreme merit; and there are also fine collections at Vienna, Berlin, and Florence.

Mining (see also *Ency. Brit.*, ninth edition, vol. xvi.).

1. *Occurrence*.—In the case of the precious metals several new and interesting discoveries may be mentioned. The three principal are the gold deposits of the Witwatersrand, Cripple Creek, and West Australia. In the year 1885, when first the news came that gold was being found to the south of Pretoria, no one dreamt of the vast importance of the discovery. The metal is there found in several beds of conglomerate, which are interstratified with sandstone and quartzite. The conglomerate consists of quartz pebbles, often the size of a walnut or larger, cemented together in the main by silicious matter and iron pyrites. The gold is contained almost entirely in this cementing material, the quartz pebbles themselves being usually barren. As in the case of other pyritiferous deposits, the parts near the surface are decomposed into oxides, with liberation of the gold, and the easily-worked rusty conglomerate was the source of riches in the earlier days of Johannesburg. The fears that the passage of the oxidized ores into pyrites meant disappearance of the gold are now allayed, and mining engineers do not hesitate to propose to work the pyritiferous beds at a depth of 5000 feet or more. Cripple Creek is a small but rich gold-bearing district in Colorado, where the precious metal occurs largely in combination with tellurium. The tellurides are found in sheets of fissured volcanic or granitic rock altered by mineral solutions. The principal tellurides appear to be calaverite. The state of West Australia attracted little attention until the wonderful discoveries at Coolgardie proclaimed it to be a rich gold-bearing country. The gold occurs native in quartz veins, and also more particularly as a telluride. The so-called "lode formations" of Kalgoorlie are zones of shattered igneous rock, so crushed as to be often schistose in texture, in which tellurides have been deposited. There is no marked sharp plane of division ("wall") separating the auriferous deposits from the surrounding rocks. Here, as at Cripple Creek, we have examples of the doctrine of "selective porosity"—that is to say, certain zones of rock are rich, because the metal-bearing solutions found the fissured portions to be the easiest channels for their passage, and coursed with greater abundance through them. In other words, where the path was easy and the flow abundant, the deposition was copious; impermeable belts of rock received no nourishing currents, and remained barren. This theory may further be advanced as an explanation of the fact that the conglomerates, *i.e.*, coarse or more permeable sediments, in the Transvaal contain payable quantities of gold, whilst the fine sediment, the sandstone, is barren or poor. The Cripple Creek and Kalgoorlie gold deposits are remarkable instances of veins or lodes which are tabular masses of altered rocks, and not merely filled-up fissures.

2. *Prospecting*.—The searcher is now often better equipped for his work by having acquired an elementary knowledge of mineralogy and blowpipe analysis. In some cases a knowledge of geology has had far-reaching effects; the most brilliant example of the result of geological reasoning is the discovery of coal in Kent. Carefully conducted magnetic observations with the Thalen and Tiberg instruments have proved valuable in prospecting for magnetic iron ore. Professor H. Louis has improved the American dipping needle, and finds that it may be usefully applied in searching for deposits of pyrrhotite, which may be rendered valuable by the accompanying nickel or copper ore.

3. *Boring*.—No one process of percussive boring can claim universal adoption. The old Chinese system of boring with the rope has been brought to a high pitch of perfection in the United States, where it has been and is

still largely used for drilling oil wells. In Europe rods, either of iron or wood, seem to be preferred, though rope boring is by no means unknown. Fauck of Vienna has introduced an improvement by substituting a quick short stroke for the old-fashioned slow and long stroke; and by combining this method with the water-flushing system he has attained great rapidity and economy in boring. The rods are hollow, and a stream of water is constantly being forced down through them to the very bottom of the hole, as in the case of the diamond drill. The débris are therefore removed as fast as they are produced, and there is no necessity for stoppage for clearing out the hole. If cores are required, Fauck employs a special chisel with a large central hole, and instead of forcing down water through the rods, pumps it up. The cores are sucked up in this manner, and are delivered piece after piece into a receiving box at the surface. Years of experience with the diamond drill have led to the introduction of sundry improvements. Instead of fixing the black diamonds in the crown itself, each separate stone is often set in a piece of steel, which can be let into a suitable recess in the crown. The advantages of this method are, firstly, firmer setting and consequently less danger of loss of the stone; and secondly, the possibility of shifting stones from one crown to another without resetting. A crown with steel teeth, exchangeable with the diamond crown, has been successfully used for the softer strata, as in the Davis calyx system. It has been abundantly proved that bore-holes frequently deviate very considerably from the straight path they were intended or supposed to take, and in some cases it becomes very important to determine the amount and direction of the deviation. McGeorge's clinograph is one of several ingenious appliances which have been used.

4. *Excavation*.—Everywhere there is a growing tendency to substitute power-driven machines for hand tools. The power may be generated on the spot, but in the case of underground excavations it is usually transmitted by water, compressed air, or electricity. The air-compressors most commonly used work dry—that is to say, there is no injection of water. The cooling of the air in the cylinder is affected by an outer jacket with a constant flow of water. Two-stage compressors with an intermediate cooler enable a pressure of 90 lb per square inch to be reached without difficulty. The machines used in excavating may be classified as follows:—A. Diggers and dredgers; B. Machines for boring holes for blasting; C. Groove-cutters; D. Tunnelling machines and shaft-sinking machines.

A. The principal types of *mechanical excavators* are the steam navy, or steam shovel, as it is commonly called in the United States, the grab dredge, and the bucket or ladder dredge. The steam shovel is a huge scoop worked by a small steam engine standing on a truck, which also carries the steam boiler. The whole machine runs upon rails which are laid down as the excavation proceeds. The amount of work done by these machines is enormous. A 90-ton "Vulcan" steam shovel dug up and loaded into railway cars no less than 170,000 gross tons of iron ore in twenty-six days at the Mountain Iron Mine, Minnesota. This type of excavator is employed very largely for stripping off overburden and for quarrying iron ore. It is also seen in some of the open workings for anthracite in Pennsylvania; it is used for loading iron ore from stock piles into railway waggons, and when mounted on a barge it will scoop up auriferous gravel and sand from the bed of a river. Grab dredges are semi-cylindrical or semi-spherical buckets, raised and lowered by cranes, and so constructed that they open on being lowered, fill themselves, and then close on being raised. The bucket is then swung round by the crane and made to drop its contents into a railway waggon or other receptacle. The grab, or "clam-shell" dredge, as it is usually called in the United States, is principally used for excavating under water. Bucket or ladder dredges resemble the well-known machines in common use for deepening river channels and harbours. They find their most important sphere of action in raising gold-bearing sand and gravel from the beds of existing rivers, or from adjacent alluvial flats. New

Zealand has profited greatly by this method of working, and fully one-seventh of the gold produced by this colony is extracted in this manner, which is exceedingly economical. According to an official report published in 1899, the cost of dredging the gravel, washing out the gold, and getting rid of the waste is only from 1d. to 3d. per cubic yard. The addition of the tailings elevator is an important improvement.

B. Of *machine drills* there are two main types, viz., rotary and percussive. Rotary drills worked by water, compressed air, or electricity are in common use. Brandt's hydraulic drill, with a toothed steel crown, has increased its reputation by enabling two of the "ends" of the Simplon tunnel to be driven at the enormous speed of 22 feet per day through hard rock. Motors driven by compressed air or electricity can easily be made to communicate rotary motion to a twist drill, and machines of this description are to be found in various mines in which comparatively soft materials, such as coal and ironstone, are being excavated. Percussive drills are worked by compressed air or by electricity of the former kind two principal varieties may be distinguished, according as the cutting chisel is attached to the moving piston-rod or receives blows from a mechanical hammer in imitation of the hand tool. The former type is by far the more common, and in fact at the present time is the one almost universally adopted. The machines, though called by various names, have often very much in common, and are distinguished merely by some slight difference in the valve. The hammer-action machines more or less resemble the caulking, chipping, and riveting tools of the ship-yard, and are mechanical hammers which strike several thousand blows per minute upon the head of the chisel. There appears to be a great future for appliances of this kind, in which the extreme rapidity of the stroke makes up for the want of power of each particular blow. A most important point in their favour is their lightness. The Franke drill of the Mansfeld mines, which is held in the hand, weighs only 16 lb; the small Schmucker drill weighs 35 lb, and the large one 80 lb. The Schmucker drills require stands, but they are far lighter and more easily handled than the percussive drills in common use. The new Leyner drill, a heavier machine with a less rapid stroke, is distinguished by its good water-flushing arrangement. Electrically-driven percussive drills are not yet largely employed, in spite of the urgent need which exists of a suitable machine. The problem of obtaining a reciprocating motion by means of an electrical current is solved in two ways. The Marvin drill, already used in a few workings, is based upon the principle of the solenoid. The electric current passes alternately through two coils of copper wire, and converts them into magnets sufficiently strong to suck the tool-holder backwards and forwards; the backward stroke compresses a spring, the recoil of which aids the forward blow. The second method consists in employing rotary motors, from which a back-and-forward action is easily obtained by the aid of a crank. Siemens and Halske, who have already supplied several hundred percussive electric drills, keep the motor entirely separate from the striking part. It is placed in a box on the floor of the working place, and its rapidly rotating axle is connected to the drill proper by the aid of flexible shafting. The drill proper is thus rendered much lighter and more easily handled. The same method is followed in the Gardner electric drill.

C. *Groove-cutters*.—Mechanical groove-cutters serve in quarrying stone, and for undercutting beds of coal or other minerals. There are many varieties: mechanical chisels, boring machines mounted on bars along which they can be shifted, travelling jumpers running upon rails, circular saws, endless chain armed with cutting teeth, wire saw, revolving toothed bar, blade with scythe motion. Mechanical chisels are largely employed in coal mines in the United States for the purpose of undercutting (*holing*). The best-known machines are the Harrison, the Ingersoll, and the Sullivan. This type of coal-cutter consists of a strong cylinder, with an air-driven piston, mounted on a couple of wheels, and having handles at the back to enable the operator to turn it in the desired direction. Into the end of the piston-rod is fitted a strong chisel, the blows of which are directed against the bottom of the bed of coal, the underlying shale, or some parting of waste, so as to chip out a groove corresponding to the "holing" of a hand-wielded pick. According to Mellin (*Glückauf*, vol. xxxvi. p. 1057), one-quarter of the bituminous coal raised in the United States in 1900 was undercut mechanically, and 1907 out of a total of 3125 machines in use belonged to the type just described. There is every reason to believe that the rapidity of the rise in the production of coal in the United States is largely due to the introduction of coal-cutting machinery. Franke's small groove-cutter, used at the Mansfeld copper mines, is a chisel which is struck several thousand blows a minute by a pneumatic hammer. There is no reason why tools of this description should not be used for "holing" coal. If a series of holes are bored in a line and almost touching each other, it is easy to make a groove by breaking down the intervening partitions. Several of the well-known manufacturers supply quarry-bars upon which their boring machines can be mounted, so as to bore the necessary set of holes in a vertical or inclined

position and produce a severance along any desired plane. In the third type, of which the Wardwell channeller is a good example, compressed air or steam is made to communicate a reciprocating motion to a set of chisels clamped together; the machinery is mounted upon a carriage running upon horizontal rails which are laid upon the surface of the bed of stone to be cut. The chisels cut a vertical groove, which can be prolonged indefinitely as the machine travels. Other machines will cut an inclined groove if necessary. The so-called "disc-cutters" are circular saws mounted upon carriages which travel upon rails laid along the working face. The saw is driven by an electric motor or a compressed-air engine, and as the carriage is drawn along automatically, the saw makes a long undercut in the seam of coal or other mineral which has to be worked. The armed endless chain likewise does its work by a sawing action. Upon a frame shaped like an isosceles triangle are fixed three pulleys, a driving pulley at the apex and a guiding pulley at each of the other two angles. A chain is kept continually in motion around the frame by means of a compressed-air or electric motor working the driving pulley. The chain is armed with steel teeth at suitable intervals. The short side of the frame opposite its apex is brought against the face of the coal, and when the chain is set in motion its teeth cut a groove parallel to this side; all the time the chain is cutting, its frame is being mechanically fed forwards at right angles to the line of the groove, so that eventually the coal is undercut over a space equal to the width of the frame multiplied by the amount of the forward feed, say 5 feet by 6 feet. The frame is then withdrawn, and the machine shifted sideways so as to begin a new cut. This kind of machine requires a considerable amount of open space at the working face, and therefore it cannot be used unless the roof is strong enough to remain without supporting timber for some distance. It is chiefly used for "pillar and stall" workings. The wire-saw may be regarded as a kind of band saw. It is an endless strand composed of three steel wires, which is kept moving upon the rock while sand and water are fed to it. The grains of hard sand are caught in the spaces between the wires, dragged along, and so made to abrade the stone and cut a groove. The wire is kept constantly pressed against the bottom of the groove by the aid of two pulleys, one at each end of the cut. In the case of a vertical cut these pulleys are placed upon suitable frames in small pits, and are so arranged that they can be fed downwards by the aid of screws. The wire-saw is employed in various open marble quarries for making long cuts in the live rock and for subdividing the blocks afterwards, and it has also been applied to the "getting" of slate in underground slate quarries. It is made to cut a horizontal groove over a space 170 feet long by 39 feet wide, and the work is done at a cost of only 16d. per square yard. This application of the wire-saw to horizontal cutting may have very far-reaching effects. Monticolo has introduced what he calls a "penetrating pulley," which enables the terminal pits to be dispensed with, or rather to be replaced by two inexpensive bore-holes. The mode of action of the revolving toothed bar will be understood by looking upon the cutting tool as a gigantic round rasp standing at right angles to the working face, and revolving rapidly, while the frame, which carries it and its driving machinery, is made to travel upon temporary rails laid parallel to the working face. Fayol's coal-cutter is a toothed blade to which a scythe-like motion is imparted by a compressed-air motor. Like the disc-cutters, these two last machines require a small amount of free space, and may be made to travel for an unlimited distance along an uninterrupted face of long-wall workings, cutting a continuous groove.

D. *Tunnellers* are machines which cut out a drift in one operation, or, at all events, an annular groove which will render the completion of the drift a very easy matter. Stanley's "heading" machine consists of a strong axle standing in the centre line of the drift and made to revolve by the aid of compressed-air engines. It carries a cross-head with large teeth at each end; these cut an annular groove as they revolve, and in soft rocks, such as coal, the work of complete excavation is speedily accomplished with the pick. The machine cuts a circular tunnel 5 feet in diameter. It has been proposed to apply this principle of mechanically cutting an annular groove to the case of sinking shafts through fairly hard ground, but no large undertaking of this kind has been carried out at present. On the other hand, shafts are being sunk on the Continent by several ingenious rotary boring processes in soft ground or through quicksands.

5. *Explosives*.—In no branch of mining has more progress been made than in the manufacture of mining explosives, particularly with the object of supplying materials which can be used with safety in collieries. A conviction has gradually come over the mining world that many of the worst explosions in collieries have been due to the ignition of gas, or of a fine coal dust floating in the atmosphere, by the flame of the explosive used in blasting, especially when the shot, instead of rending the coal, blows out the tamping like a ball from a cannon. It is to the French Firedamp Commission that we are specially indebted for early scientific investigations upon the subject. They ascertained that if the gases given

off by an explosion have a temperature exceeding 2200° C., they are liable to ignite firedamp, and a law was made prohibiting the use of gunpowder altogether and permitting only such explosives as have a temperature of detonation considerably below the limit just named. Austria, Belgium, Germany, and Great Britain have followed the example of France in endeavouring to supply the miner with explosives possessing a reasonable amount of safety, and a special statute (59 and 60 Vict. c. 43) was passed in Great Britain in 1896 to give the Secretary of State full statutory powers for dealing with the question. An official testing station has been erected at Woolwich; the explosives which pass the test are placed upon what is known as the "Permitted List," and their use is then sanctioned. In order to enable mine-owners to ascertain which are the safer of the explosives in this list, which includes some that barely succeed in satisfying its conditions, the British Government has instituted a "Special Test," which is far more severe than the first. Not only in explosives themselves, but also in the means of firing them, much progress has been made. Cheap and trustworthy electric fuzes are now manufactured on a very large scale, both on the high- and the low-tension systems, and are used with advantage instead of the ordinary safety fuze. Where it is necessary to delay the ignition of certain shots until others have been exploded, electric time fuzes are available. In Austria several other methods of ignition have received the approval of the authorities, such as Tirmann's percussion fuze, Laner's friction fuze, and Jarolimek's lime fuze. Though the old process of fire-setting is extinct save on a small scale in very out-of-the-way districts, the agency of heat is invoked by the miner for the purpose of thawing ice-bound auriferous alluvium and so facilitating the process of excavation. Prospectors in Siberia have long been accustomed to sink their shafts by the aid of heat generated by burning billets of wood. In the Klondike district this process of thawing has been largely replaced by the use of steam. A boiler is erected at the surface and steam is taken down the shaft in a pipe, a hose from which conducts it to the working place. At the end of the hose is a piece of iron pipe terminating in a small hole. Steam is turned on, and the pipe is passed into the frozen gravel and left there. After the lapse of three or four hours a large mass of gravel has been thawed, and can easily be worked away with the pick.

6. *Principles of employment of mining labour.*—Persons employed at mines are still paid by time, by work accomplished or calculated by measuring or weighing, or by some settled proportion of the value of the mineral excavated, as described in the ninth edition of this work (vol. xvi. p. 449).

7. *Support.*—Three kinds of supporting materials are still in use, viz., timber, metal, and masonry, the last heading including both brickwork and concrete.

In order to reduce the expense of cutting the somewhat complicated joints required for "square sets," mines now use special machines consisting of circular saws so arranged as to make the necessary cuts. Machines like huge pencil-sharpeners are employed for tapering the ends of props when Hepplewhite's system is adopted. Preservatives against dry rot are not commonly used, in spite of the advantage of prolonging the life of the timber and rendering it less inflammable. Aitken's process of impregnating the timber with a solution of the chlorides of sodium and magnesium has been found very effective at certain collieries in Scotland. Steel is becoming a favourite supporting material in many countries, and especially for permanent levels and shafts. It possesses many advantages, especially durability, small size compared with timber and consequent increase of ventilating area, and is free from danger from fire. The H-section is usually adopted, and two bars suitably bent into an arched form at the top, which can be quickly and firmly united by fish-plates, form an admirable lining for a level. The ground between two adjacent frames may be further supported by small rods of square section. This kind of support is common in many French collieries. Where the bottom of a level is liable to rise, from the pressure upon it, the steel lining is sometimes made of two semicircles suitably joined by sleeves. Shafts are lined with circular frames of channel steel, each frame consisting of two or more segments united by suitable fish-plates and bolts; the space between two successive frames is lined with planks or with bars of steel. The commonest permanent lining for round shafts in Great Britain is brickwork; but concrete is gradually coming to the front, on account of its two great advantages, viz., speed of execution and economy in price. In northern France, where cast-iron lining (*tubbing*) is common, it is usual to employ segments with *internal* flanges which are bolted together. The staunchness of the joint is secured by interposing thin sheet lead. The Poetsch method of sinking in water-bearing strata by artificially freezing the ground (see COAL) was successfully applied in many instances at the end of the 19th century, and the boring processes

associated with the names of Kind and Chaudron, which afford another solution of the problem of putting down a shaft through water-bearing rocks, have been considerably simplified in some of their later applications. The moss-box and equilibrium pipe have been dispensed with, and the engineers have relied upon very carefully placed concrete for making a staunch joint at the base of the tubbing.

8. *Exploitation.*—The methods of working away minerals have been arranged by Haton de la Goupillière in three great classes, according as the original excavation is left open permanently, is allowed to "cave" in of itself, or is artificially filled up with rubbish. On the whole, it may be said that the third method is gaining ground, and is being largely employed, not only in collieries, but also in working beds of slate and wide mineral veins. Though hydraulic mining in principle remains as it was, attention may be drawn to some successful applications in Australia, where alluvial flats are being worked with great success under conditions which would make the process impossible if carried out in the typical Californian manner. The necessary pressure for the powerful jet of water is obtained not by its natural fall, but by a steam pump; the stream of mud, sand, and gravel coming away from the working face is raised by a centrifugal pump, passed along gold-catching sluices, and, when deprived of its gold, is run into a part of the excavation whence the gold has already been extracted, and gradually fills it up. The steam boiler, the pump which generates the pressure, and the centrifugal pump are all carried upon a barge of very shallow draught, so that when work is finished at a given spot it is easy to float the plant to a short distance and repeat the operation until the whole flat has been treated.

9. *Haulage.*—More and more attention is being paid to the substitution of mechanical power for animal power in mines. In addition to the older process of haulage by wire rope or chain, the mine-owner now has at his disposal successful methods of doing the work by electricity and compressed air. Electric locomotives are usually operated by overhead wires with trolleys connecting them with the motor. Accumulators have been little used, though they have been adopted at the Vicoigne and Nœux collieries in the Pas de Calais. The compressed-air locomotive is adopted in fiery mines in order to secure freedom from sparks. The Porter locomotive is supplied from a large reservoir which is charged with air at a pressure of 600 lb per square inch.

10. *Winding.*—Flat ropes made of the so-called aloe fibre are still largely employed in France and Belgium, but hoisting is generally performed by round ropes of steel wire of a high tensile strain, often capable of supporting no less than 180 kilos per square millimetre, or, speaking roughly, 120 tons per square inch. Ropes with the so-called Lang's lay, in which the spirals of the strands are turned in the same direction as the spirals of the individual wires, have proved by long practice to last longer than ropes made upon the old principle. In order to make the surface of the rope more nearly approach that of a cylinder, and so to throw the wear upon a large number of wires, the strands are sometimes made oval by employing flat wire for the core. These "flattened strand ropes" have given good results. Casting aside entirely the principle of making wire ropes of separate strands, we come to the so-called locked coil ropes. Specially-shaped wires—V-shaped or S-shaped, for instance—are used, and in section the rope is seen to consist of several successive concentric sheaths, each composed of interlocking wires. The outer surface of the rope is cylindrical; no space is wasted, and a rope of given diameter is able to support a greater weight than one made in the old way. The carefully kept statistics concerning the life and wear of winding ropes in Westphalia are not, however, favourable

to the locked coil variety for hoisting purposes. The clumsy kibble hanging loose in the pit, or sliding along a bed of planks or poles in an inclined shaft, is fast disappearing, and in mines worked on a large scale the material is hoisted either in a cage, which carries the waggon, or in a steel box called a skip. Both cage and skip are properly guided. Efforts are constantly being made to increase the rapidity of hoisting. Machinery is employed to push the waggons from the cage, or the cage is so arranged that its floor is tilted automatically on reaching the surface, and causes the waggons to empty themselves without leaving the cage. The skips, whether hoisted up inclined or vertical shafts, are made to turn over automatically on reaching the surface, discharge their contents, and return to their original position without the aid of a workman (see COAL). For the prevention of accidents in winding, speed indicators and automatic speed-checking appliances have been introduced in various mines. Less reliance than formerly is placed upon safety catches, and especially in Great Britain, where, on the whole, they are regarded with little favour. No progress has been made in pneumatic hoisting, for the colliery where Blanchet's apparatus was in use had to be abandoned for lack of coal, and the system has not been tried elsewhere.

11. *Drainage*.—The most important drainage tunnel in course of construction at the present time is that which is being driven from Marseilles to unwater the Gardanne lignite mines, situated at a distance of more than 9 miles (15 kilometres) from the sea. The importance of this gigantic undertaking may be measured by the fact that the total cost is estimated at about a quarter of a million sterling. The work was to be finished by the end of 1902. It is calculated that the great adit will unwater 40,000,000 tons of lignite, besides enabling more than 100,000,000 tons to be worked from depths not exceeding 300 metres below it. When pumps have to be employed, the tendency is to abandon the old Cornish method of raising water, which consists in employing a slow-working single-acting beam engine with a ponderous main-rod to transmit power from the surface to a series of force pumps in the shaft, which step by step raise the water to the top. Nowadays the main pump is frequently placed in a chamber near the bottom of the shaft, and is made to force the water to the surface in one continuous column. The force-pumps are driven (*a*) by steam engines, the steam for which is usually generated at the surface and piped down the shaft; (*b*) by hydraulic engines driven by water under pressure brought down in pipes from the surface; (*c*) by compressed-air engines; (*d*) by electric motors connected by wires with dynamos on the surface. A type of electric pump in common use consists of three plungers actuated by a three-throw crank, driven by a quick-running motor, with suitable intermediate gearing or a belt for reducing the speed. Now engineers have gone further, and by diminishing the length of stroke of the plungers they have found it possible to run them at such a speed that the intermediate gearing is dispensed with entirely and the crank shaft coupled direct to that of the motor. Riedler and Stumpf's "Express" pumps are driven directly from electric motors or other high-speed prime movers making 200 to 300 revolutions a minute, and are employed for forcing considerable quantities of water to a maximum height of 1886 feet (575 m.). Ehrhardt and Schmer likewise make mine pumps with the crank coupled directly to the shaft of an electric motor running at 200 to 300 revolutions a minute, and forcing 200 to 300 gallons (1 to 1½ cb.m.) of water per minute to heights of 800 to 1000 feet (250 to 300 m.), the cranks running in oil. They contend that mechanically controlled valves, a special

feature of Riedler's pumps, can be dispensed with. It is manifestly unfair that one mine should be saddled with the expense of pumping more than its share of water because it happens to be deeper than its neighbours, and the difficulty is sometimes met by establishing a drainage board—*i.e.*, a corporate body whose sole business it is to drain the water from a definite area and make each mine pay a share of the expense. The scheme has worked well in South Staffordshire, where, in addition to maintaining large pumping engines, the Drainage Commissioners have done excellent work by preventing surface water from finding its way into the mines. At Mansfield also measures have been taken to prevent surface percolation.

12. *Ventilation*.—Though many mines, and especially workings on mineral veins, are dependent for their supply of air solely upon natural currents, the standard method of ventilation is by centrifugal fans, which have to a large extent entirely replaced the old furnaces, with great advantages of economy and safety. The main fan is placed at the surface, and acts almost invariably by exhausting the foul air from the mine. Sometimes certain working places in the mine are specially ventilated by small fans driven by electric motors or compressed-air engines. The fans most in use are those of Capell, Geissler, Guibal, Mortier, Rateau, Schiele, Ser, and Waddle. Murgue has devised an ingenious appliance, which shows the volume of air passing through a mine at any given moment, and registers it upon a scroll of paper placed around a cylinder, which revolves by clockwork. The curve which is traced resembles that of a self-registering aneroid barometer, and affords a useful check upon the mine officials, besides forming an important record in case of any disputes. Murgue has also done good work by pointing out the large amount of power expended in overcoming the friction of the air currents against the sides of mine passages, especially those which are timbered, and by explaining the manner in which such friction can be reduced. The means of testing the air of mines have been improved. Instead of depending upon the indications of an oil lamp, the searcher for fire-damp may now avail himself of the far more delicate alcohol flame. Chesneau's lamp, largely used in French collieries, burns alcohol containing chloride of copper, and the flame tinged by the metallic salt gives an indication of fire-damp when the amount of gas exceeds 0.1 per cent. Stokes has brought out a lamp with a detachable alcohol reservoir, which enables the oil flame or an alcohol flame to be used at pleasure. Le Chatelier's laboratory method of determining the amount of fire-damp in a sample by the limit of inflammability of a mixture of the gas and air, is regularly employed in some collieries. Shaw's more cumbersome apparatus depends upon the same principle. (Also see COAL.)

13. *Lighting*.—The safety lamp most largely used at the present day is that of Marsaut, though the name of the eminent French engineer is often ignored by manufacturers. It is a safety lamp with two or more gauzes and an outer shield capable of resisting strong air-currents with safety. The use of mineral oil in place of vegetable oil is spreading. Many safety lamps are now lighted electrically, with a great economy of time and trouble. An appliance for relighting a safety lamp which has gone out accidentally is largely used at some collieries on the Continent, and is considered by many engineers to be a valuable addition. A roll of paper, with little spots of a material ignitable by friction or a blow, is fitted close to the top of the wick and is rubbed or struck without opening the lamp, the flame so produced igniting the wick. The commonest method of preventing the illegal opening of safety lamps underground is by the lead plug; the magnetic lock finds favour in

some collieries; and the ingenious cavalier, or water-pressure lock, is not without adherents. Much labour has been expended in endeavouring to devise a portable electric lamp for use in mines, but, so far, the Sussmann lamp is the only one which can claim to have been introduced on a large scale. Several thousands of these lamps are employed at collieries in England and Belgium.

14. *Ascent and Descent.*—The standard method of descent into mines and ascent therefrom is by the cage or the skip; even in the most conservative ore-mining districts managers are recognizing the absurdity of making a miner waste his strength and endanger his health by excessive ladder-climbing, and this mode of reaching and leaving the workings is disappearing. The man-engine, which has done good work in its day, is likewise doomed to extinction, now that strong steel ropes enable cages to be raised and lowered with so much rapidity and safety. (See ORE-DRESSING.)

15. *Legislation.*—Laws for rendering the miner's calling less dangerous are found in most civilized countries, and the amount of legislation in recent years has been great. The Acts of Parliament in the United Kingdom, and the mining law of the late South African Republic, may be taken as typical examples of laws for regulating the working of coal and ore mines respectively. The mines of coal, fire-clay, shale, and stratified ironstone in Great Britain are governed in the main by the Coal Mines Regulation Act of 1887 (50 and 51 Vict. c. 58). The Coal Mines Regulation Act of 1896 (59 and 60 Vict. c. 43) was passed with the prime object of giving the Secretary of State power to regulate the use of explosives in mines where blasting might cause dangerous explosions by igniting fire-damp or an atmosphere charged with coal dust. All the mines in the United Kingdom not covered by the Coal Mines Act are governed by the Metalliferous Mines Regulation Act, 1872 (35 and 36 Vict. c. 77). Its title is bad, as it regulates not only ore mines, but all underground workings for salt, slate, stone, &c. The Transvaal Law (Law No. 12, 1896) was a general mining statute dealing with many questions besides the safety of the workman. It was far ahead of the British Metalliferous Mines Act. Mine managers were required to give proof of their competency by passing an examination, plans had to be kept up by competent surveyors, and far more complete statistics of output had to be furnished than was the case in Great Britain.

16. *Accidents.*—It is a matter of great congratulation that mining is every year becoming a less dangerous occupation, and this assertion can be proved by reference to official statistics which are so abundantly furnished by many countries. One point in preparing these statistics is sometimes forgotten, viz., the necessity of calculating the death-rates of the underground workers separately. If the death-rate of the true miner is watered down by mixing it up with that of surface workers, who have a comparatively small risk, conclusions will be erroneous.

TABLE I.—Death-rate from Accidents in and about the Mines of the United Kingdom per 1000 Persons employed, in 1891 and 1900.

YEAR.	Death-rate from Accidents per 1000 Persons.							
	Underground Workers taken separately.						Surface Workers taken separately.	General Death-rate of all persons employed both Above and Under Ground.
	Explosions of Fire-damp or Coal-dust.	Falls of Ground.	Shaft Accidents.	Miscellaneous.	All Causes Underground.			
1891 . . .	·091	·894	·236	·438	1·660	·864	1·493	
1900 . . .	·070	·790	·133	·452	1·445	·699	1·289	
Average for 10 years . . .	·175	·791	·158	·463	1·586	·800	1·423	

In the early 'fifties the underground death-rate was more than 5 per 1000, whilst, taking all the mines together, both under the Coal Mines Acts and Metalliferous Mines Acts, the average death-rate of the underground workers in 1900 was only 1·445; this is slightly higher than the corresponding figures for the two previous years,

though lower than the average for the previous decade, which was 1·586. The general decline in the death-rate from accidents in Great Britain is shown graphically for the years 1873-1900 by Figs. 1 and 2, and numerically for 1891 and 1900 by Table I. Fig. 3 shows the proportions in which each class of accident swelled the total during the last half of the 19th century. The small importance of explosions, compared with falls of ground, is very striking. What can be done to combat falls has been shown by the Courrières Colliery Company in France. By systematic timbering, increased supervision, and the employment of iron bars as temporary supports to the roof in advance of the last row of props, the death-rate from falls at Courrières has been reduced to 0·15 per 1000, or $\frac{1}{6}$ of what it used to be, and $\frac{1}{5}$ of the British death-rate from falls in 1900. Without indulging in optimistic hopes, it may fairly be assumed that the general death-rate of miners from accidents can be brought down below 1 per 1000 per annum, a figure which may be conveniently taken to denote the borderland between hazardous and non-hazardous occupations. British statistics point to the attainment of this desirable goal in the early years of the 20th century. In some other countries such a result will be delayed on account of the employment of unskilled labourers, fearless to a fault, and imperfectly acquainted with the language of their masters and some of their companions. Thus the death-rate from accidents at the diamond mines of Kimberley, and the gold mines of the Transvaal and Mysore, far exceeds that in Great Britain.

17. *Mineral Statistics.*—The output of mines and quarries of the United Kingdom in 1900 was as follows:—

TABLE II.—General Summary of Mineral Produce.

Description of Mineral.	Quantity.	Value at the Mines and Quarries.
	Tons.	£
Alum Shale	1,308	164
Arsenical Pyrites	9,573	8,710
Arsenic	4,081	67,028
Barytes	29,456	29,244
Bauxite	5,779	1,350

Minneapolis, the capital and leading city of Minnesota, U.S.A., situated on both banks of the Mississippi river at the Falls of St Anthony. With the "twin" city of St Paul it constitutes the centre of the commercial life of the north-west, sharing the termini of the Northern Pacific, Great Northern, Canadian Pacific ("Soo" Line), St Paul and Duluth, Chicago and North-Western, Chicago and Great Western, Minneapolis and St Louis; Chicago, Burlington, and Quincy; Chicago, Milwaukee, and St Paul; and the Wisconsin Central Railways. Dams are being constructed by the Federal Government below the city, which will make Minneapolis the head of navigation on the Mississippi. Communication with St Paul is secured, besides the steam railways, by an electric line. Minneapolis possesses a street-car system of some 120 miles of tracks. Its population in 1895 was 192,833, and in 1900, 202,718, of whom 61,021 were foreign-born (largely Scandinavian) and 1548 were negroes. The birth-rate is 13.54 per 1000, and the death-rate (1900) only 10.8. The public school system has 59 buildings, 4 of which are high schools, and there are 782 teachers. The school attendance in 1899 was 34,863. In 1900 the United States census reported 60,377 persons of school age (5 to 20 years inclusive). Out of 63,711 males of voting age, 1205 were illiterate (unable to write), of whom 1065 were foreign-born. In addition to the public schools, there are three preparatory schools, a medical college, an art school, and a conservatoire

of music. The higher institutions of learning are the Augsburg theological seminary and the University of Minnesota. The public life of the city is indicated in its library of 106,000 volumes, art gallery, park system, 18 miles of boulevards, 170 churches, 3 theatres, 4 daily newspapers, 43 weekly, 6 semi-monthly, 27 monthly, and 2 quarterly periodicals. In finance and manufacturing Minneapolis has made rapid progress. There are 6 national banks, 6 state and savings banks, and 4 trust companies with a combined capital of \$8,536,000. In 1899 the bank clearings reached the sum of \$539,400,176. The deposits in these banks in the same year amounted to \$34,604,720. During 1899 buildings to the value of \$3,052,500 were erected. In 1900 there were 2368 manufacturing establishments, with a capital of \$57,708,204, and products valued at \$110,943,043. There were 26,608 wage-earners employed (exclusive of 2606 salaried officials, clerks, &c.), who received in wages \$12,708,523. The principal output consisted of lumber and timber products, valued at \$12,285,305, and flouring and grist-mill products, valued at \$49,673,568. In 1899 the jobbing or wholesale business amounted to \$100,000,000. The assessed valuation of real and personal property in 1900, on a basis of about 60 per cent. of the full value, was \$99,492,054, and the rate of taxation \$27.40 per \$1000. The bonded indebtedness was \$8,550,000, but there was a sinking fund of \$1,872,115. The cost of the city government was \$2,882,719. (F. L. McV.)

Minnesota, one of the north-central states of the United States, situated between 43° 30' and 49° 25' N. and 89° 29' and 97° 5' W. In 1885 the population was 1,117,896, an addition in five years of 43 per cent.; in 1890 it was 1,301,826, or 16.4 persons to the square mile; and in 1900 it was 1,751,394, and the density 22.1 per square mile. In 1895 the population comprised 1,057,084 native-born persons and 517,535 foreign-born. Of these 119,554 were born in Sweden, 107,319 in Norway, 133,768 in Germany, 49,831 in Canada, 26,106 in Ireland, and 70,957 in other countries. Of the total population in 1900, 932,490 (53.2 per cent.) were males and 818,904 (46.8 per cent.) females; 1,246,076 native-born and 505,318 (28.9 per cent.) foreign-born; 1,737,036 were white and 14,358 (0.8 per cent.) coloured, of whom 4959 were negroes, 166 Chinese, 51 Japanese, and 9182 Indians. The death-rate in 1900 was about 9.7 per cent. The urban population, classing as such all persons in cities of 8000 inhabitants or over, was 470,046, or 26.8 per cent. of the total population, as against 28.2 per cent. in 1890. In 1890 the population of the forty cities and villages with over 2000 inhabitants was 456,214; but in 1900 it had increased to 52 with a combined population of 629,398. Since 1880 the three largest cities have had a rapid growth. In 1880 Minneapolis had a population of 46,887, St Paul 41,473, and Duluth 838. In 1890 the respective figures were 164,738, 133,156, and 33,115. In 1900 the populations were as follows: Minneapolis 202,718, St Paul 163,065, and Duluth 52,969.

Religion.—In 1890 there were thirteen denominations with over 5000 members. Of these the Roman Catholics had 271,319 members; the Lutherans (of all denominations), 136,914; the Methodists, 30,387; the Baptists, 14,698; the Presbyterians, 13,734; the Congregationalists, 13,624; and the Episcopalians, 11,142.

Charities and Corrections.—In 1860 there were in the state institutions 23 inmates, or one to every 8826 of the population. In 1898 the number had increased to 5671, or one for every 306. The expense of maintaining these was \$2,829,723. The insane asylums are at St Peter, Rochester, Fergus Falls, Anoka, and Hastings, and the schools for the deaf, dumb, blind, and imbecile at Faribault. The soldiers' home is at Minnehaha Falls, and the school for neglected and dependent children at Owatonna. Young boys and girls under sixteen are sent for certain offences to the training school at Red Wing. Young men between sixteen and

thirty are committed to the state reformatory at St Cloud for the first offences. Criminals are sent to the state prison at Stillwater. Under the Act of 2nd March 1883 the Legislature created a board of six persons to supervise the entire system of public charities and correctional institutions, which was appointed by the governor, and served without recompense. By Act of the Legislature in 1901, however, its work and powers were placed in the hands of three persons known as the Board of Control. The members are appointed by the governor, and hold office for six years.

Education.—Illiteracy had fallen to 5.9 per cent. in 1890. This was due to the public school system, which includes a series of closely associated institutions from the primary school to the university. The schools proper are under the general supervision of a high school board consisting of a principal of an independent state high school appointed by the governor, the president of the university, and the superintendent of public instruction. The Legislature in 1899 made an appropriation for the aid of the schools of the state, which has been apportioned by the high school board. Rural schools receive \$75 per year; semi-graded schools, \$100; graded schools, \$200; and high schools, \$800. The number of pupils enrolled in 1898 was 364,063. At that time there were 6415 common schools, 151 independent schools, 25 special, 97 state high, and 110 state graded schools. The value of the school houses and apparatus was \$15,277,500. The support of the public schools comes from two sources, taxation and the interest from a permanent school fund now amounting to \$12,087,627. There are five normal schools at Winona, Mankato, St Cloud, Moorhead, and Duluth, with an attendance in 1898 of 3052. Regular appropriations are made for their support by the state legislature. The State University in Minneapolis has faculties of literature, science, and art; of agriculture, of law, of medicine, and of engineering, and the schools of chemistry and mines. The attendance is 3400; the income—derived from a $\frac{3}{8}$ mill tax, from students' fees, from United States appropriations, and from interest on endowment—is about \$380,000 per annum. The Legislature has supplemented the public school work by creating a system of travelling libraries, farmers' institutes, and local option free text-books. In 1900 the number of persons of school age (5 to 20 years inclusive) was 612,990. Out of 506,794 males of voting age, 20,785 were illiterate (unable to write), of whom 16,780 were foreign-born and 1378 Indians.

Banks.—The banks on the 1st of February 1899 were divided as follows:—National 72, capital \$13,750,000; state banks 149, capital \$6,500,000; savings banks 14, with deposits of \$11,000,000, and 47,328 depositors; trust companies 8, capital \$3,664,226; and 206 private banks with a capital of \$3,975,500. With the exception of the private banks, all are under the supervision of the state examiner.

Finances.—The income is derived from twenty different sources, and in the year ending 31st July 1898 amounted to \$5,429,240, while the expenditure was \$5,298,942. There was a balance in the treasury of \$2,184,612. The expenditure for 1899 and 1900 was estimated at \$3,086,660 and \$2,607,812. The state debt is \$1,475,647. In 1899 the total valuation of all classes of property was \$585,083,328. On this amount taxes were levied to the amount of \$14,539,285, the state receiving \$2,026,774. The principal source of income, outside the personal and property taxes, is a 4 per cent. tax on the gross earnings of railway, express, telephone, telegraph, fast-freight and sleeping-car companies. The total tax levied for all purposes averaged for the whole state 24.85 mills.

Agriculture.—In 1900 there were in the state 154,659 farms, containing 26,248,498 acres, of which 70.3 per cent. were improved land. The total value of farm property was \$788,684,642, made up as follows:—Land, improvements and buildings, \$669,522,315; implements and machinery, \$30,099,230; live stock, \$59,063,097. The increase in the total value of farm property during the decade 1890–1900 was \$373,983,016, or over 90 per cent. Of the total number of farms, 82.7 per cent. were worked by owners, 3.3 per cent. by cash tenants, and 14 per cent. by share tenants. The total value of farm products for the year 1899 was \$161,217,304. Statistics of the principal crops are given in the following table:—

Crops.	Acres	Quantity.	Value.
Indian corn . . .	1,441,580	47,256,920 bushels	\$11,397,105
Wheat . . .	6,560,707	95,278,660 "	50,601,948
Oats . . .	2,201,325	74,054,150 "	15,829,804
Barley . . .	877,845	24,314,240 "	7,220,739
Flax seed . . .	566,801	5,895,479 "	5,898,556
Hay and forage . . .	3,157,690	4,411,667 tons	14,585,281
Potatoes . . .	146,659	14,643,327 bushels	3,408,997
Miscellaneous . . .			
vegetables . . .	27,438	...	1,372,907
Forest products	2,602,335

The number and value of the most important domestic animals were as follows:—753,632 dairy cows, \$21,513,337; 1,117,693 other neat cattle, \$14,735,621; 696,469 horses, \$42,255,044; 8500 mules and asses, \$498,055; 359,328 sheep (not including lambs), \$1,329,531; 1,440,806 swine, \$5,865,590.

Mining.—In 1884 the great iron ranges were little known; only 62,124 tons had been taken out of the Vermilion range. The Mesabi range mines were opened in 1892, and in 1898 the two ranges produced 5,878,908 tons of ore. The total tonnage since 1884 is 28,492,256. Several valuable mines have been leased to private companies on terms that require payment in advance and a second payment on the execution of the contract. Up to 31st July 1898 the state had made 2520 prospecting leases, twenty-six of which are in force. There are also eighty-six mining contracts in force. The royalties paid into the state treasury from such contracts in 1897 and 1898 amounted to nearly \$51,447. The private mines are largely controlled by eastern syndicates. The ore is shipped to Ashtabula, Cleveland, Buffalo, and Erie from Two Harbors, Duluth, and West Superior by way of the great lakes.

Manufactures.—The general statistics of manufactures in 1890 and 1900 are shown in the following table:—

	1890.	1900.	Per cent. of Increase.
Number of establishments	7,505	11,114	48.1
Capital	\$127,686,618	\$165,832,246	29.9
Salaried officials, clerks, &c.	9,839 ¹	7,319	25.6 ²
Salaries	\$7,818,116 ¹	\$6,554,424	16.2 ²
Wage-earners (average number)	69,790	77,234	10.7
Total wages	\$30,371,123	\$35,484,825	16.8
Miscellaneous expenses	\$12,136,612	\$13,273,648	9.4
Cost of material used	\$118,481,941	\$173,425,615	46.4
Value of products	\$192,033,478	\$262,655,881	36.8

The principal industry is milling. In 1900 the manufacturing establishments for flouring and grist-mill products numbered 512, and employed an average number of 4086 wage-earners. The capital invested in this industry amounted to \$24,125,781. The products were valued at \$83,877,709, or 15 per cent. of the total value of the flouring and grist-mill products of the United States. Not only did Minnesota lead in this industry among the states of the Union, but the like products in the state next in rank (New York) amounted in value to only a little more than half as much. A very large export trade in flour has been built up, amounting in 1898 to 4,000,000 barrels. Lumber and timber products rank next in importance, being valued in 1900 at \$43,585,161. In this industry there were 438 establishments, with a total capital of \$52,095,923, and employing 15,140 wage-earners. The lumber product in 1898 was 1,687,762,000 feet of board lumber, 440,511,000 shingles, and 315,869,000 lath. It is estimated that there is still standing in the state 13,000,000,000 feet of pine. At the present rate of cutting this would disappear within a few years, but undoubtedly the cut will decline each year. The products of slaughtering and meat-packing (wholesale) amounted in 1900 to \$6,803,112, and the value of cheese, butter, and condensed milk produced at factories amounted to \$8,479,896. The leading manufacturing centre in the state is Minneapolis.

Commerce.—The jobbing or wholesale trade is estimated at \$600,000,000. The two customs districts with ports of entry at Duluth and Minnesota City, recorded \$4,410,303 worth of exports, and \$1,743,204 of imports in 1899.

Railways.—The facilities for transportation are exceptionally good. The railway mileage in 1899 was 6338. Three trunk lines cross the state to the Pacific coast, six lines extend from the twin cities to Chicago, and a number run from north to south. In 1898 the capital stock and bonds of these railways were \$1,157,061,160. Minnesota's proportion on a mileage basis was \$264,326,776. The gross earnings of the railways for that year, inside the state, amounted to \$43,903,818. The Federal Government has given these railways 17,621,952 acres, and the state 3,548,719 acres—a total of 21,170,671 acres. Of this 10,234,598 acres have been patented by the state to the railways.

History and Politics.—The state has been undisturbed by strife, with the exception of the rise of the Pillager Indians in October 1898, which was quelled by the United States army. The immediate cause of the outbreak was the attempt to arrest certain Indians who were engaged in the illegal sale of whisky within the reservation. The arrest was resisted by the Indians, and led to

disturbance. But the resistance was intensified by injustice done to the Indians in connexion with the sale of their lands, and made the incident from their point of view an effort towards vindication. In politics the Republican party controlled state elections for forty years after the admission of the state into the Union. In 1898 this long history was broken by the fusion of the forces of the Democrats and Populists, which elected their candidate for governor. The Democratic-Populist candidate received 131,980 votes, while the Republican received only 111,706. In the presidential election of 1900, out of a total vote of 313,087, McKinley (Republican) received 190,461 votes, and Bryan (Democratic) 112,901.

Constitutional Changes.—Important changes have been made in the constitution since 1880. The requirements of citizenship are more rigorous; only full citizens of the United States are permitted to exercise the franchise, and these only after a residence of six months in the state and thirty days in the district. Special legislation was restricted by constitutional amendment in 1891, as a result of which it was impossible for cities to obtain any revision of their charters except by general Act. It was therefore necessary to amend the constitution so as to permit citizens to frame charters for their respective municipalities. This was done in 1896. Any city of over 1000 inhabitants may secure a new charter by appointing a charter commission to draw such an instrument. The charter must be submitted to the people within six months after the appointment. A four-sevenths vote makes it the basis of the city organization. The session of the Legislature has been increased to ninety days. In civil actions a jury after six hours' deliberation may render a verdict by a five-sixths vote. Combinations against trade are prohibited by the constitution. The governor may veto a part of a money Bill without invalidating the remainder.

Minsk, a government of western Russia, bounded on the N. and E. by Vilna, Vitebsk, and Moghilev; on the S. and W. by Chernigov, Kieff, Volhynia, and Grodno. Area, 35,293 square miles. Its population in 1897 was 2,156,123, of whom 1,078,466 were women, and 228,822 lived in towns. They were distributed as follows, according to religion:—Greek Orthodox, 71.3 per cent.; Jews, 17.3; Catholics, 10.1; Greek Nonconformists, 0.8; Mussulmans, 0.3; Protestants, 0.2 per cent. The peasants constitute 65 per cent. of the population. The average yearly crops of 1893–98 were: rye 6,720,000 cwt., wheat 1,507,000 cwt., oats 3,314,300 cwt.; all cereals 13,067,000 cwt. Gardening is carried on in some districts. There were in 1895, 259,000 horses, 690,000 horned cattle, and 560,000 sheep. The chief industrial establishments are distilleries, breweries, steam flour-mills, tobacco, and various factories for dealing with forestry produce. Their aggregate returns amounted in 1897 to £1,742,700. Archaeological finds of great value, dating from the Neolithic and subsequent ages, have lately been made. Of schools there were, in 1897, 1827 and 726 Jewish *heders*, with an aggregate of 67,130 pupils (8580 girls). The government is divided into nine districts, of which the chief towns and populations are: Minsk, capital of the government, 91,494 inhabitants in 1897; Bobruisk (35,177), Igumen (4579), Mozyr (10,762), Novogrudok (7700), Pinsk (27,938), Ryechitsa (9322), and Slutsk (14,180).

Minster, or MINSTER IN SHEPPEY, a parish and village in the Isle of Sheppey, Kent, England, 3 miles south-east of Sheerness. The church of SS. Mary and Sexburga was formerly part of an ancient convent church. In 1894 the parish was reduced by the formation out of it of the civil parish of Sheerness. It is connected with Queenborough by a light railway, opened in 1901. Population (1891), 1307; (1901), 1292.

¹ Includes proprietors and firm members, with their salaries.

² Decrease.

Minto, William (1845–1893), Scottish man of letters, was born at Anchintoul, Aberdeenshire, in 1845, and educated at Aberdeen University and Merton College, Oxford, winning high honours in classics, mathematics, and philosophy. He was assistant professor under Alexander Bain at Aberdeen for some years, and between 1874 and 1878 was editor of the *Examiner*; he subsequently wrote for various newspapers, and in 1880 was made full professor of logic and English at Aberdeen. In 1872 he published a *Manual of English Prose Literature*, which was very successful, and was distinguished by sound judgment and sympathetic appreciation; and his *Characteristics of English Poets* (1874) showed the same high qualities. He contributed *Daniel Defoe* (1879) to the "English Men of Letters" series, and was also the author of two novels, *The Crack of Doom* (1886) and *The Mediation of Ralph Hardelot* (1888). He died in 1893.

Minusinsk, a district town of Russia, East Siberia, government of Yeniseisk, 220 miles south of Achinsk railway station, 5 miles from the right bank of the Yenisei, situated in a fertile prairie region. It is a centre for trade (annual value, £100,000) with the native populations of the Sayans and north-western Mongolia. It has one gymnasium for girls, and an excellent natural history, ethnographical, and archæological museum (1877), with a library and a meteorological station. The industry is chiefly agricultural; large herds of cattle are kept, but there is a variety of small trades. Population (1897), 10,255.

Miquel, Johann von (1829–1901), German statesman, was born at Neuenhaus, Hanover, on 21st February 1829. He sprang from a French family which had emigrated during the Revolution. He learnt law at the universities of Heidelberg and Göttingen, and at an early age studied the writings of Karl Marx. For a time he became a convert to the extreme revolutionary, socialistic, and atheistic creed; but though he entered into correspondence with Marx, with the object of starting a revolutionary movement, he does not appear to have taken any overt part in the events of 1848–49. Further study of political economy soon enabled him to pass out of this phase, and in 1850 he settled down to practise as an advocate at Göttingen. He acquired repute as an able lawyer and a rising politician, was one of the founders of the National-Verein, and in 1864 was elected member of the Hanoverian Parliament as a Liberal and opponent of the Government. He accepted the annexation of Hanover by Prussia without that regret felt even by many Liberals who belonged to older Hanoverian families, and was one of the three Hanoverians whose brilliant parliamentary abilities at once won a commanding position in the Prussian and German Parliaments. For some reason, perhaps because Bismarck did not entirely trust him, he did not at this time attain quite so influential a position as might have been anticipated; he was chairman of the parliamentary committee by which in 1876 the new rules of legal procedure were drafted, but he found scope for his great administrative abilities in the post of burgomaster of Osnabrück (1865–1870 and 1876–80), and was also from 1870 to 1873 a director of the Discontogesellschaft, the most important of German banks. In 1880 he was elected burgomaster of Frankfort-on-Main, where he gained great reputation for the energy with which he dealt with social questions, especially that of the housing of the poor. Probably owing to his early study of Socialism, he had never adopted the economic as well as the political doctrines of Liberalism, and he was very ready to support the new State Socialism of Bismarck. He was the chief agent in the reorganization

of the National Liberal party in 1887. After Bismarck's fall he was chosen as Prussian minister of finance, and held this post for ten years. He distinguished himself by his reform of the Prussian system of taxation, an important series of measures to which the financial prosperity of Prussia is largely attributed, and the one really successful measure of the new reign in internal affairs. An attempt to reform the system of imperial finance in 1893–94 failed, and much injured his reputation. In all the political controversies and intrigues of the time he took a leading part, but it is impossible to explain here the course of his policy, which was not always clear. He had entirely given up his Liberalism, and aimed at practical measures for improving the condition of the people irrespective of the party programmes; some of his measures, such as that for taxing "Warenhäuser," i.e., stores, were of a very injudicious nature. He professed to aim at a union of parties on the basis of the satisfaction of material interests, a policy to which the name of *Sammlung* was given; but his enemies accused him of constantly intriguing against the three Chancellors under whom he served, and of himself attempting to secure the first place in the State. The sympathy which he expressed for the Agrarians increased his unpopularity among Liberals and industrials, and added to the difficulties of the Administration to which he belonged; but he pointed out that the State, which for half a century had done everything to help manufactures, might now attempt to support the failing industry of agriculture. In June 1901 the rejection of the canal Bill led to a crisis which probably took the form of a trial of strength between him and Bülow, and he was obliged to send in his resignation. His health was already failing, and he died on 8th September of the same year at his house in Frankfort. He left the reputation of a statesman in ability second to none of those who had risen to power under the Empire, who only failed to reach the highest rank because of a restless ambition and an uncertainty in action which prevented men from depending on him whether as leader or colleague.

Miraj, a native state of India, in the Deccan division of Bombay, forming part of the southern Mahratta Jagirs. Since 1820 it has been subdivided between a senior and a junior branch. The territory of both is widely scattered among other native states and British districts. Area of the senior branch, 339 square miles; population (1891), 88,343; average density, 260 persons per square mile; gross revenue (1897–98), Rs.2,81,883, of which Rs.86,605 was expended on public works and Rs.32,808 on famine relief; tribute, Rs.12,558; number of police, 335; 29 schools, with 2691 pupils. Area of the junior branch, 225 square miles; population (1891), 35,487; gross revenue, Rs.3,47,657, of which Rs.46,431 was expended on public works; tribute, Rs.6412; number of police, 137; 31 schools, with 1362 pupils. The chiefs are Brahmans by caste, of the Patwardhan family. The town of MIRAJ, at which both chiefs have their residence, is situated in 16° 49' N. and 74° 41' E., near the river Kistna; it is a junction on the Southern Mahratta railway for the branch to Kolhapur. It has a high school, with 244 pupils in 1897–98, and two state printing-presses. Population (1881), 20,616; (1891), 26,060.

Mirgorod, a district town of Little Russia, government of Poltava, 90 miles north-west of the town of Poltava, 14 miles from the Kharkoff–Nikolaieff railway. It is an old town, which played an important part in the wars between Little Russia and Poland. Population, (1897), 10,023.

Mirzapur, a city and district of British India, in the Benares division of the North-West Provinces. The

city is on the right bank of the Ganges; a station on the East Indian railway, about half-way between Allahabad and Benares, 509 miles north-west from Calcutta. Population (1881), 85,362; (1891), 84,130; and (1901), 79,787; municipal income (1897-98), Rs.60,360, almost entirely from octroi; incidence of taxation, nearly 10 annas per head; registered death-rate (1897), 60.86 per thousand. Formerly it was the emporium of trade between northern and central India, which has now been diverted to the railways. It has two European and 39 native lac factories, the latter employing 2400 hands, with an out-turn valued at Rs.9,72,000. The London Mission manages a high school. There are three printing-presses, one of which issues a newspaper in vernacular and English.

The district of MIRZAPUR extends into the Sone valley. Area, 5223 square miles; population (1881), 1,136,796; (1891), 1,161,508; (1901), 1,082,706; showing an increase of 2 per cent. between 1881 and 1891, but a decrease of 6.8 between 1891 and 1901; average density, 207 persons per square mile. The land revenue and rates are Rs.9,71,735, the incidence of assessment being less than 8 annas per acre; cultivated area (1897-98), 385,808 acres, of which 45,495 were irrigated from wells, &c.; number of police, 2156; number of vernacular schools, 103, with 4856 pupils; registered death-rate (1897), 51.7 per thousand. The district is permanently settled, and comprises a large part of the hereditary domains of the Raja of Benares, which are revenue-free. It is traversed, near the Ganges, by the main line of the East Indian railway for 53 miles. The Great Southern road used to start from Mirzapur city. There are no Government canals.

Mishawaka, a city of St Joseph county, Indiana, U.S.A., on the St Joseph river, at the intersection of the Grand Trunk and Michigan Southern railways, in the northern part of the state. Its manufactures consist largely of agricultural tools and machines. Population (1890), 3371; (1900), 5560, of whom 821 were foreign-born and 21 were negroes.

Misiones, a territory of the Argentine Republic, bounded on the E. by Brazil, from which it is separated by the rivers Pepiri (also called Pepiri-Guazu) and San Antonio, on the S. by Brazil, on the N. by Brazil, and on the W. by Paraguay and the Argentine province of Corrientes. The official area at the census of 1895 was 11,282 square miles; and in 1895 the population was 33,163. The capital, Posadas, was founded in 1865. The territory is divided into fourteen administrative divisions. In 1895 there were 2519 farms in the territory, and 15,630 acres planted in cereals; 70,259 head of cattle, and 25,002 horses.

Miskolcz, a corporate town of Hungary, capital of the county of Borsod, with 32,288 inhabitants in 1891, and 43,096 in 1900. It has two gymnasia, a commercial school, an orphanage, a hospital, and is an important centre of trade and traffic.

Missions.—This article is mainly devoted to the extension of missionary work since 1884, with some reference to previous events not fully dealt with in the article on the subject in the earlier volumes of this work. It is generally agreed that the years since 1885 have witnessed a very marked increase of missionary zeal and interest in Great Britain, both in the Church of England and among the Nonconformists. The improvement, indeed, dates back somewhat earlier. So far as the Church of England is concerned, it may fairly be said to have started

afresh in the year following the first observance of the Day of Intercession for Missions, 20th December 1872. Both the Society for the Propagation of the Gospel and the Church Missionary Society were at that time suffering from a general coldness which, in the case of the latter society, had led in that very year to the committee reporting "a

failing treasury and a scanty supply of men." The observance of that first Day of Intercession was followed by an immediate change, and unquestionably there has been progress ever since. Then, less than five months afterwards, David Livingstone died at Ilala; and no event of the whole century did so much to wake up Protestant Christendom. Most of the Missions in Central Africa owe their origin to the spirit it aroused. But the year 1884, from which the present survey mainly starts, was also an epoch to be marked. In that year Bishop Hannington went to Africa; and his murder in 1885 (first reported in England on New Year's Day, 1886) deeply touched the Christian conscience. The speedy publication of Mr Dawson's biography of him worked a revolution in the circulation of missionary literature. Not only was the sale of the book itself large, but it encouraged publishers to bring out other works on Missions. Another event of 1884-85 was the going forth to China of the men known as the Cambridge Seven, in connexion with the China Inland Mission. All were men of good family; some of them went at their own charges; and among them were the stroke-oar of the University Eight (Mr Stanley Smith) and the captain of the University Eleven (Mr C. T. Studd). Probably no event of recent years has exercised a wider influence in the cause of Missions. In particular, university graduates have since then gone out as missionaries in much larger numbers than before. There are now five Missions definitely linked with the universities. The Central African Mission (1858), indeed, is not for the most part manned by graduates, though it is led by them; but the Cambridge Mission at Delhi (1878), the Oxford Mission at Calcutta (1880), and the Dublin Missions in Chota Nagpore (Society for the Propagation of the Gospel, 1891) and the Fuh-Kien Province of China (Church Missionary Society, 1887) consist of university men. Moreover, the older and larger societies have much increased the proportion of graduates on their staffs, the Society for the Propagation of the Gospel and Church Missionary Society having between them about 300 engaged in actual missionary work among the heathen (besides the S.P.G. colonial clergy).

The cause of Missions in the universities has been fostered in the last few years by the Student Volunteer Missionary Movement, initiated in America in 1886, and organized in England in 1892. Between 1892 and 1902 no less than 1880 students in colleges in the United Kingdom (including theological colleges and medical schools) signed a declaration expressing their purpose, "if God permit," to be foreign missionaries; and of these, 733 had sailed by February 1902 in connexion with various societies, Anglican and Nonconformist. The Student Volunteer Missionary Union has adopted as its watchword, "The Evangelization of the World in this Generation"; and this motto has been approved by several bishops and other Christian leaders. Another influence upon university men and others who have taken holy orders is that of the Younger Clergy Union of the Church Missionary Society (1885), and the Junior Clergy Association of the Society for the Propagation of the Gospel (1891). Some 4000 clergymen have joined one or other of these organizations, and while more than 100 have gone out as missionaries, the members generally have been incited to the study of Missions and to efforts for their support. At the same time there has been a great accession of men to the missionary ranks from among other classes of society. The Anglican societies and the regular and older Nonconformist societies (Methodist, Baptist, Presbyterian, and the London Missionary Society, which is virtually Congregationalist) have shared in these humbler recruits; but a large proportion of them have joined several younger "non-denominational" or "inter-denominational" Missions.

Of these the China Inland Mission is the largest and most influential; and while it has sent forth many of this class, it has also enrolled not a few men and women of considerable wealth, education, and social status. The South Africa General Mission, the North Africa Mission, and the Congo Balolo Mission come next in importance; but there are several smaller bodies working in different countries. The Salvation Army also has missions in India, Ceylon, and Japan; but these cannot be called "non-denominational," because the Army has gradually become a very strict denomination itself. There is one Anglican society working, like some of those just mentioned, in one particular field, viz., the South American Missionary Society, founded in 1844. Many foreign dioceses also have associations in England for their help and support. Medical men have come forward in increasing numbers for missionary service, and Medical Missions are now regarded as a very important branch of the work of evangelization. They are especially valuable in Mahommedan countries, where open preaching is difficult and sometimes impossible, and also in works of mercy among barbarous tribes; while in China, which comes under neither of these two categories, they have been largely developed. About 500 fully qualified doctors are labouring in British and American Missions; and in 1898 it was calculated that the in-patients in British Mission hospitals exceeded 30,000, while the visits of out-patients in a year were nearly a million and a half. In several of the great London hospitals there are missionary associations, the members of which are medical students; but a chief source of supply in the past has been the Edinburgh Medical Mission, founded in 1841, which, while working among the poor in that city, has trained many young doctors for missionary service. Of course the total number is only a small fraction of the whole body of medical men; but the same remark applies to other classes of missionaries, clerical and lay.

The most remarkable development of missionary enterprise has been the employment of women. From an early date many of the wives of missionaries have done good service; but the going forth of single women in any appreciable number has only been encouraged by the societies in the last quarter of the 19th century. The Society for Promoting Female Education in the East (now absorbed by others, chiefly by the Church Missionary Society) was founded in 1834; the Scottish Ladies' Association for the Advancement of Female Education in India (which subsequently became two associations, for more general work, in connexion with the Established and Free Churches of Scotland respectively) in 1837; the Indian Female Normal School Society (now the Zenana Bible and Medical Mission) in 1861 (taking over an association dating from 1852); the Wesleyan Ladies' Auxiliary in 1859; the Women's Association of the Society for the Propagation of the Gospel, and the Baptist Zenana Mission, in 1867; the London Society's Female Branch, in 1875; the Church of England Zenana Society (an offshoot from the Indian Female Society) in 1880. But the earlier of these organizations only contemplated employing women for educational work, on a very small scale. Out of it grew the visitation of Indian zenanas. The employment of women in general evangelistic work, such as village itineration, house-to-house visiting in towns, classes for female inquirers, training of native female workers, &c., although recent, has rapidly extended. The Church Missionary Society, besides relying on the above-named Zenana Bible and Medical Mission and Church of England Zenana Missionary Society for women's work at several of its stations in India and China, sent out 500 single women in the fifteen years

ending 1900; and the non-denominational Missions above referred to have (including wives) more women than men engaged in their work,—especially the China Inland Mission, which has sent out several hundreds to China, and in 1900 had just 300 (unmarried) on the roll. Women's work and medical work are combined in the persons of about eighty fully-qualified lady doctors in various Missions. Although nearly half the male missionaries (Protestant) are unmarried, these are exceeded in number by the unmarried women; and consequently, the husbands and wives being equal, the aggregate of women in the Missions is greater than the aggregate of men. If the total number of British missionaries, including wives, is taken at 7000, the married men would stand at about 1900, and their wives at 1900, the single men at 1400, and the single women at 1800; but this is an estimate in round figures.

The home organization of Missions is a subject that has been much considered. The bulk of the work has been done by voluntary societies, membership in which depends upon a pecuniary subscription, and the administration of which is entrusted to elected committees. These committees comprise not only real experts, such as retired veteran missionaries, and retired civil and military officers who have been active friends of Missions while on foreign service, but also leading clergymen and laymen who, though not personally acquainted with the mission fields, become almost equal experts by continuous attendance and careful study. In the case of the two leading Church of England societies, the bishops (being members) are *ex officio* on all executive committees; but their labours in other directions prevent their ordinarily attending. The numerous non-denominational Missions previously referred to are differently worked. There is no membership by subscription, nor any elected committee. The "Mission" consists of the missionaries themselves, and they are governed by a "Director," with possibly small advisory councils in the field and at home, the latter undertaking the duty of engaging missionaries and raising funds.

On the other hand, there is a growing sense that Missions should be the work of the Church in its corporate capacity, and not of voluntary associations. This is the system of the Presbyterian Churches, the Missions of which are entirely controlled by the General Assemblies in Edinburgh, Belfast, and London respectively. The Wesleyan Society also is under the authority of the Conference. In the Church of England the question was broached in Convocation, shortly after the revival of that body, in 1859; and during the next few years many suggestions were put forth for the establishment of a Board of Missions which should absorb the societies, or at least direct their work. It soon appeared, however, that neither the Society for the Propagation of the Gospel nor the Church Missionary Society was willing to be absorbed; and it was urged by some that in a great comprehensive national Church, comprising persons of widely different views, more zeal was likely to be thrown into voluntary than into official enterprises. Eventually, in 1887, the Canterbury Convocation and Archbishop Benson formed a Board of Missions; and York followed shortly afterwards. These Boards, however, were not to supersede the societies, but to supplement their work, by collecting information, fostering interest, registering results, and acting as referees when required. They have already done some useful work, and will probably do more. Their most active members are men who are also leaders in their respective societies, and have thus gained experience in missionary administration. But the Church of England has not yet put Missions in the prominent place they occupy in the Nonconformist denominations.

When the Baptist Union holds its annual session, the first day is devoted to a review of the Baptist Missions. Convocation has not yet adopted a similar procedure.

The closing years of the 19th century were remarkable for the centenary commemorations of the older missionary societies. The Baptist Society celebrated its centenary in 1892; the London Missionary Society (Congregationalist) did the same in 1895; the Society for Promoting Christian Knowledge kept its bi-centenary in 1898; the Church Missionary Society its centenary in 1899; the Society for the Propagation of the Gospel its bi-centenary in 1900-01; and the British and Foreign Bible Society was founded in 1804. Considerable special funds have been raised in connexion with these commemorations.

Colonial Missions next claim attention. By "colonial" is meant not missions to the British colonial population, but Missions from the colonial population to the heathen.

The former have been very largely the work of the Society for the Propagation of the Gospel, and, in a smaller degree, of the Colonial Church Society (Church of England) and the Colonial Missionary Society (Nonconformist). Those Missions, however, are more properly an outlying branch of home Missions, being to the professing Christian settlers or their descendants. But these Christian settlers have their own Missions to the heathen—both to the heathen at their doors and to the great heathen lands beyond.

In Canada and Australia, the Anglican, Presbyterian, Methodist, Baptist, and other communities have regular organizations for foreign Missions. The non-Episcopal Missions thus formed and supported are worked quite independently of the home societies of the denominations respectively. The Australian Presbyterians have important agencies in the South Seas and in Korea, the Australian Baptists in Bengal, the Canadians of various denominations in the Far North-West of the Dominion, and in India and China. The Anglican Church in Canada has its Domestic and Foreign Missionary Society, working in the North-West and in Japan; and in Australia it has a Board of Missions, working amongst the Australian aborigines and in New Guinea. The Melanesian Mission, associated with the names of Selwyn and Patteson, is officially connected with the Church of New Zealand, but is also largely supported in Australia. In New South Wales, Victoria, New Zealand, and Canada there are also Church Missionary Associations which supply missionaries, and support them, for the mission fields of the Church Missionary Society.

The *German* societies are numerous and important, and have increased in number and in vigorous work. The *Moravian Church*, whose Missions are the oldest (1732), is itself a missionary organization

in a sense in which no other Christian community rivals it. Its total membership is under 100,000, and it has some 350 missionaries, labouring in the most unpromising fields, Greenland, Labrador, Alaska, Central America, Tibet, and among the Hottentots. The *Basel Society*, with its famous seminary at Basel, which formerly supplied many able German missionaries to the Church Missionary Society, has extensive work in India, West Africa, and South China. The *Berlin Society* and the *Rhenish Society* labour in South Africa and China, the *Hermannsburg Mission* (Hanover) in South Africa and India; *Gossner's Mission* (Berlin) and the *Leipzig Lutherans* in India. At least two of these societies, and other new associations formed for the purpose, and the Moravians, have taken up work in German East Africa. In 1900 German missionaries numbered 986, and their converts were estimated at 370,000. The principal organization in *Holland* is the Netherlands Missionary

Society, working in the Dutch East Indies. A *Danish* Society has a mission in South India. The old *Swedish* and *Norwegian* Missionary Societies work in South Africa, Madagascar, and India; but large numbers of Scandinavians have been stirred up in missionary zeal, and have gone out to China in connexion with the China Inland Mission; several were massacred in the Boxer outbreaks. The *French* Protestants support the *Société des Missions Évangéliques*, founded in 1822. Its chief mission has been in Basutoland, since extended to the Zambezi; but it has also followed French colonial extension, establishing missions in Senegambia, the French Congo, Madagascar, and Tahiti.

The newer American organizations are, as in England, non-denominational and "free-lance," especially the Christian Alliance under the direction of a popular minister at New York, the Rev. A. B. Simpson, which has sent many missionaries to India and China. The older societies attribute to these new agencies more zeal than discretion, while the newer credit the older with a discretion that cripples zeal. The Student Volunteer Movement, already referred to, has had large influence in the United States, where it arose; and its leaders have proved themselves men of rare intellectual and practical capacity. In a journey round the world in 1895-97, Mr J. R. Mott succeeded in forming students' associations in universities and colleges in several European countries, as well as in Turkey in Asia, Syria, India, Ceylon, China, Japan, and Australia; and all these associations, nearly 100 in number, are now linked together in a great International Student Federation, of which a Swede is chairman and a Japanese vice-chairman. The older American societies, especially the American Board (Congregationalist), the Presbyterian Boards, the Methodist Episcopal Church Society, the Baptist Missionary Union, and the Missionary Society of the Protestant Episcopal Church, have much extended their work. The "Ecumenical Missionary Conference" held at New York in April 1900 was an astonishing revelation to the American public of the greatness of Missions generally, and of the Missions of their own Churches in particular. American missionaries number about 4800.

Missions to the Jews are distinct from Missions to heathen and Mahomedans, and are worked by distinct organizations. There are several societies in England, Scotland, Germany, and America. No special development has to be reported, except the great extension of Mr John Wilkinson's *Mildmay Mission to the Jews*, and its energy in the free distribution of Hebrew New Testaments. Converted Jews are commonly supposed to be very few, and in numbers they do not compare with converted heathen; but they are more numerous than is usually imagined, especially if the second and third generations of Christians of Hebrew race are included. It is estimated, for example, that 250 Anglican clergymen are converted Jews or the sons of converted Jews. The London Society for Promoting Christianity among the Jews includes among its missionaries about 80 who are converts. Professor Deitzsch estimated that 100,000 Jews had embraced Christianity in the first three quarters of the 19th century; and Dr Dalman of Leipzig says that "if all those who have entered the Church and their descendants had remained together, instead of losing themselves among the other peoples, there would now be a believing Israel to be counted by millions, and no one would have ventured to speak of the uselessness of preaching the Gospel to the Jews."

At the beginning of the 19th century the Roman Communion seems to have shared to some extent in the torpor

4. *American.*

5. *Missions to the Jews.*

and stagnation as regards Missions that characterized the Protestant Churches. There was little of the zeal which had carried the Franciscans all over Asia in the 13th century, and the Jesuits to South America, India, and Japan in the 16th. But the 19th century has witnessed a great change, and Roman Catholic Missions have been extended *pari passu* with Protestant. The revival was not a little due to the foundation in 1822, by a few earnest but (as they called themselves) "humble and obscure" Catholics at Lyons, of a new voluntary society called the Institution for the Propagation of the Faith. It collected in its first year about £2000 from the shopkeepers and artisans of Lyons. Thirty years later its income was £200,000 a year; and now it is £300,000. It has sent out no missionaries of its own. It merely makes grants to the various missionary parties sent forth, and it has done much in this direction. Roman Missions are carried on both by missionary societies and by religious orders, all under the supreme direction of the Pope, and also more or less under the general supervision of the Congregation de Propaganda Fide at Rome since its foundation in 1622. The Congregation of Lazarists was founded at Paris by St Vincent de Paul in 1632, and the Société des Missions Étrangères, also at Paris, in 1663. This last-named society is the largest Roman Catholic missionary organization, labouring all over eastern Asia and parts of India. It had, in 1899, 34 bishops, 1100 missionaries, 680 native priests, and 1,227,000 native Christians. In that year it baptized 46,000 adult pagans, 41,000 children of Christians, and 155,000 "children of pagans *in articulo mortis*." Several other smaller societies have their headquarters in Belgium, Italy, and Ireland. For the purpose of Missions in Africa several modern congregations have been formed, particularly the Congregation of the Holy Ghost and Heart of Mary, the Lyons Society of African Missions, the Institute of Verona, and the Algerine Congregation for the conversion of Central Africa (White Fathers). An English organization, St Joseph's Foreign Missionary Society, was founded by Cardinal Vaughan at Mill Hill, near London, about 1870. It had in 1900 two bishops and 86 priests in the mission field, and works in Uganda, north and south India, Borneo, and New Zealand. The religious orders are also largely represented in the foreign field. The English Benedictines work in British colonies; the Capuchins in the Levant, Western Asia, North Africa, and South America; the Carmelites in India; the Dominicans in Turkey, Indo-China, North and South America; the Lazarists in China, the Levant, Persia, Abyssinia, Madagascar, and South America; the Franciscans, who have been zealous missionaries since the days of their great founder, in China, in the Philippines and Pacific islands, in North and South America, in Egypt and North Africa, in Palestine (where they are the appointed guardians of the Holy Places), and in many European countries; the Priests of the Sacred Heart in South America and the Pacific Ocean; the Oblates of St Mary in the polar regions of North America; and, lastly, the Jesuits in all quarters of the world, who in 1899 had 116 missionaries in Europe, 233 in Africa, 988 in Asia, 550 in Oceania, 1246 in North America, and 856 in South America; total Jesuit missionaries, 3989. In 1895 the Propaganda returned the number of Catholics in heathendom as 3,606,000. But this did not include North and South America, so that the total would be quite four millions. By far the greater part of the Roman missionary work is done by France. The majority of the missionaries are French (over 7000); the bulk of the money—so far as it is voluntary contribution (but the Propaganda at Rome has large endowments)—is raised in France. The French

Government, anti-clerical as it is at home, is the watchful and strenuous protector of the Missions abroad; and it is evident that not a little political influence in foreign countries is gained thereby. *L'Année de l'Eglise*, in reporting on the Missions in all parts of the world, dwells continually on this with satisfaction. Protestant missionaries are opposed, not merely because they are heretical, but because they are English or (if American) English-speaking; and the Greek Church missionaries in Persia and Japan, not only because they are schismatic, but because they are Russian—the Franco-Russian alliance notwithstanding. This is a feature in French Catholic Missions which cannot be overlooked in the briefest account of them.

AFRICA.—The old Missions on the *West Coast*, of the Church Missionary Society, the Wesleyans, and others, including several American agencies in Liberia, have continued to develop and extend. The native church organizations at Sierra Leone, Lagos, the Niger Delta, &c., are self-supporting, and the Missions proper have advanced into the interior. The professing Christians (Protestant) on the coast probably number not less than 100,000. More than 120 negroes have been ordained to the ministry of the Church of England. There are now four negro bishops, one of them (in Liberia) connected with the American Episcopal Church. Attempts have been made to reach the Mahomedan populations of the Western and Central Sudan, particularly Hausaland, but so far they have been unsuccessful. In the southern half of West Africa, *i.e.*, the *Congo Region*, there are extensive Missions of the English and American Baptist Societies, the Congo Balolo Mission, and others, all founded since 1875. Although still in their early stages, some hundreds of converts have been received. In all these regions there are extensive Roman Catholic Missions, chiefly French, of the Congregation of the Holy Ghost and the Lyons African Mission.

The *South African Colonies*, being the borderlands of native barbarism and European civilization, are among the hardest of mission fields. The Society for the Propagation of the Gospel, the London Missionary Society, the Wesleyans, the United Free Church of Scotland, the South Africa General Mission, the Moravians, the French Protestants, and some German societies, are at work among Kaffirs, Zulus, Pondos, Basutos, Bechuanas, Hottentots, &c., with considerable results, there being probably 150,000 native Christians (Protestants); and several missions now extend northwards to the Zambezi. The Church of England has nine dioceses, in all of which the work is among both colonists and heathen. The American Board (Congregationalist) has begun work on both sides of Africa, a little north of South Africa proper. There are several vicariats and prefectures of the Roman Church, the principal Missions being French, those of the Congregation of the Holy Ghost, and the Oblates of Mary.

East and Central Africa have witnessed great missionary development since 1884. The Scottish Missions in Nyasaland have gained great influence and won many converts. The church at Blantyre, connected with the Mission of the Established Presbyterian Church of Scotland, and built by the natives themselves, is a large and imposing one. The Universities' Mission, with its two bishops, and its cathedral at Zanzibar, also works on Lake Nyasa, and in several other East African districts, with increasing success. In Bishops Steere, Smythies, and Maples it added distinguished names to the roll of Anglican heroes. The London Missionary Society's enterprise on Lake Tanganyika has been disappointing, despite much patient and zealous labour. The German Missions in German East Africa are still in their infancy. Of the several Church Missionary Society Missions, Uganda has proved the most successful. In 1884 the first handful of converts had recently been baptized. There are now 30,000 baptized Christians, 2000 native teachers, 27 native clergymen, 800 churches, all supported by the converts themselves; and under Bishop Tucker's direction the Mission is branching out into the surrounding countries. The Roman Mission in Uganda, begun about two years after the Anglican one, in 1901 reckoned 8000 baptized Christians and about 16,000 catechumens. It was for some years a French Mission only, the White Fathers of Algeria, but there is now an English bishop with English priests from St Joseph's Society at Mill Hill. The Jesuits work on the Zambezi, the White Fathers in the Great Lake region, and the French Congregation of the Holy Ghost and German Benedictines on the Zanzibar coast. The French Mission at Bagamoyo has long been famous for its excellent work.

MOSLEM STATES.—*North Africa* and *Egypt* are among the hard Mahomedan fields, and so are the *Turkish Empire*, *Arabia*, and *Persia*. The American Presbyterians and Congregationalists have

The
Mission
Fields.

the largest Protestant Missions in these lands, working, however, mainly for the enlightenment and education of the Oriental Christians. With the same object, though on different lines, the archbishop of Canterbury's Assyrian Mission seeks to influence the Nestorians. The Roman Catholics have extensive Missions in these countries, directed at winning adherents to the unity of the Holy See from the Oriental Churches, which are regarded as schismatic and heretical. In this enterprise there has been great advance in Egypt among the Copts, and in 1899 the Pope signaled "the resurrection of the Church of Alexandria" by appointing a Patriarch for Egypt, Lihya, and Nubia. Farther east, on the borders of Turkey and Persia, the Roman and Russo-Greek Churches compete for the adhesion of the Nestorians, Chaldeans, and Armenians. The Franciscans, Dominicans, Lazarists, and Jesuits are engaged in all these works. Direct work among Mahomedans is done, though with small result, by the North African Mission (non-denominational) and the Church Missionary Society. The Egypt, Palestine, and Persia Missions of the latter society have been largely reinforced and extended since 1884, medical work and women's work being especially prominent. Four cities in southern Persia are now occupied. Three Missions just touch the borders of *Arabia*, viz., the United Free Church of Scotland at Aden, founded by the late Hon. Ion Keith-Falconer, Arabic professor at Cambridge; an American Presbyterian Mission on the Persian Gulf; and the Church Missionary Society's Mission at Baghdad.

INDIA.—The India Missions illustrate, as no others do, the diversities of missionary operations—bazaar preaching, village itineration, lectures and conversations, zenana visiting, vernacular schools, high schools and colleges, orphanages and boarding schools, mission hospitals and dispensaries, native church councils, and the quiet labour of linguistic translation. Almost all the great Protestant societies have their India Missions, and these have been largely reinforced. Perhaps the most notable feature is the extensive development of the American agencies, particularly those of the Episcopal Methodists, who are rapidly spreading their organization over many parts of India; but also those of the Presbyterians, Congregationalists, and Baptists. In 1890 the total number of Protestant missionaries was 975. It is probably at least 1300 now, possibly 1500. In the decade 1881-90 the Indian Protestant Christians increased from 417,000 to 559,000. The census of 1891 reported 2,036,000 native Christians, 70 per cent. of whom belonged to the Roman and Syrian Churches. The Church of England claimed 10 per cent., and the other Protestant denominations 18 per cent. The Government figures for the Protestant Christians were higher by 20,000 than those compiled by the missionary societies, showing that the latter had not over-estimated their results. The census of 1901 gives the native Christians as 2,664,359, showing an increase in the decade since 1891 of 628,359. The total is thus made up:—Roman Catholics, 1,122,378; Syro-Romans, 322,583; Jacobite Syrians, 248,737; Anglicans, 305,907; other Protestants, 561,078; miscellaneous and unspecified, 103,676. The Anglicans and other Protestants show a larger relative increase than the Roman Catholics. In 1891 the latter (including Syro-Romans) were 61 per cent. of the whole; now they are 54 per cent. There is no better gauge of real missionary success than ordinations, as they indicate the highest result of Christian training. About 400 natives of India have received Anglican orders, almost all of them since 1850; and very many of those in Presbyterian and other orders have been at least their equals in education and capacity. The large majority of baptisms in India continue to be among the non-caste or "depressed" classes of the population, comprising both the non-Aryan tribes and the lower grades of Hindus; but year by year there are numerous baptisms of Brahmans and other high-caste men, and even of the higher classes of Mahomedans. The missionary colleges and high schools have much increased in efficiency under the spur of Government examinations, and the moral results of the education they impart—even apart from conversions—are acknowledged on all hands. The great United Free Church College at Madras, under Dr W. Miller, confessedly stands in the front rank of all educational institutions. Female education is spreading, though still slowly, and chiefly among the native Christian population. The total number of women who had matriculated at the Indian Universities to 1899 was 1306. The majority were Europeans or Eurasians, but 395 were Indian women, and of these 367 were Christians, 27 Hindus, and one a Mahomedan. Roman Catholicism has made considerable progress in India, particularly in the south, and since the famine of 1877-78; but a large proportion of its adherents are descendants of the converts of the 16th and 17th centuries. The *Missiones Catholice* in 1895 gave the total as 1,391,000, including Burma and Ceylon. The *Illustrated Catholic Missions* gives it as just over 2,000,000 in 1900. The ecclesiastical organization comprises a Papal delegate at Kandy, 7 archbishops, 21 bishops, and 7 vicars or prefects apostolic; under whom are 800 European missionaries (French, English, German, Italian), 800 Goanese priests, and 700 Indian priests. The various societies and orders do not seem to be more united than the different Protestant denominations. The French Jesuits of Madura and

Tinnevely complain bitterly (in *L'Année de l'Église*) of the opposition of the Goanese as worse even than that of the pagans and Protestants. Prior to 1884 the archbishop of Goa's jurisdiction extended over the whole Roman Church in India, but in that year the Pope confined it to the Portuguese section, abolishing it in British and French territory. *L'Année de l'Église* attributes the progress of the Protestant Missions to their extensive educational work, and urges the Roman missionaries to do likewise, pointing to the success of the Catholic colleges already established.

INDIAN OCEAN.—Ceylon is a flourishing mission field. The Anglican Church there is now properly organized, with a constitution of its own. Roman Catholics and Wesleyans are also strong. *Mauritius* is an outpost of India, the work being mainly among Indian coolies. In *Madagascar* the work of the London Missionary Society, which had been among the most successful in the world, and also the work of the Society for the Propagation of the Gospel, and of the Friends' and the Norwegian Missions, have suffered much since the French conquest of the island. Gradually, however, by accepting the situation, and adopting the French language in the schools, the missionaries have conciliated the new rulers, and many difficulties have been removed, while good has resulted from the advent of the French Protestant missionaries. The French Catholic Missions are on an extensive scale, reckoning 94,000 baptized and 267,000 catechumens. *L'Année de l'Église* complains of the favour shown to the Protestant Missions by the French officials, without which, it says, those missions would have disappeared in twenty years; before the war the Protestants had two-thirds of the Christian adherents and the Catholics one-third, but the proportions have since the war been exactly reversed. In the *Malay Archipelago* the principal Missions are Dutch, and the external results are considerable. The Rhenish Society also works in the islands, especially in *Sumatra*. There is an Anglican bishop for the *Straits Settlements* and *Borneo*.

CHINA.—The years since 1880 have been a period of extraordinary extension in the Protestant Missions in China. It was not until after the Chefoo Convention of 1876 that the great pioneer journeys of the China Inland Mission men carried them into almost all the eighteen provinces. In 1878 there were 473 Protestant missionaries in China; in 1890 there were 1300; in 1900 there were 2800 (including wives). Of these, 784 belonged to the China Inland Mission; about the same number to other British societies (Church Missionary Society 189, London Missionary Society 120); about 930 to American societies; and the rest to Continental and colonial associations, or unconnected. There are four English bishops and two American. Women missionaries are especially numerous, and they have travelled with propriety and with safety (all assertions to the contrary notwithstanding) into the remotest provinces. The converts who were communicants numbered 13,000 in 1878; in 1900 they were estimated to be 100,000. The excellence of the converts, upon the whole, is testified to by travellers who really know the case; particularly by Mrs Bishop, who speaks of the "raw material" out of which they are fashioned as "the best stuff in Asia." China has been regarded as the most promising of all mission fields. The whole country has been open, even the long-closed and hostile province of Hunan; the people generally friendly, notwithstanding occasional local riots and outrages, such as the massacre of a clergyman, eight ladies and two children, in Fuh-Kien in 1895; the mandarins often displaying singular fairness in dealing with inevitable difficulties, the Government of Peking becoming more and more liberal under the young Emperor, and English education beginning to attract the upper classes, awakened from their torpor by the issue of the war with Japan. But all this was changed in 1900 by the high-handed proceedings of the Dowager-Empress, the rise of the Boxer fanatics, the struggle at the Peking embassies, the terrible massacres of 133 Protestant and 49 Roman missionaries in the northern provinces, and the withdrawal of some hundreds more from the interior by the peremptory orders of the consuls. Much of the work in the south, however, went on without interruption, and even where the missionaries had withdrawn the Chinese ministers and teachers continued their labours amongst their own countrymen. Since then the viceroys of the northern provinces have themselves invited the missionaries back. Roman Catholic Missions in China have a remarkable history from the 16th century downwards. The scientific and literary attainments of the Jesuit missionaries rendered them famous. The work is now carried on by ten societies or religious orders. There are 39 bishops and 790 European priests (600 of them French). There were 370 native priests in 1895. The Chinese Christians numbered 582,000 in that year, and are now reckoned as 661,000. *L'Année de l'Église* says that the most prominent feature of the work is the large number of baptisms of the children of pagans. In the province of Szechuen alone 85,643 children of heathen parents were baptized in 1899, a large proportion of them being baby girls thrown away by their mothers. In 1898 the Jesuits of the Shanghai mission baptized 41,400 pagan children "at the point of death." An important concession was obtained in 1899 by the French Minister at Peking, with a view to the more effective

protection of the Roman Missions. The bishops were declared "equal in rank to the viceroys and governors," and the priests "to the prefects of the first and second class"; and their influence and authority were to correspond. The Anglican bishops agreed to decline these secular powers, as also did the heads of other Protestant Missions. It is alleged by some that the exercise of the powers gained by the Roman hierarchy was one cause of the Boxer outbreaks. Certainly their native adherents had their full share of persecution and massacre.

JAPAN.—Although effective missionary work on any scale was little more than ten years old in 1884, that was a period of high hopes for the early triumph of Christianity. The Japanese newspapers openly anticipated it, and some of them welcomed the prospect. When the first Parliament, or Diet, of Japan was elected in 1890, out of 300 representatives, all leading men, 14 were Christians; and the president chosen for the Lower House was a member of the Presbyterian Church. But the following decade witnessed a change. A strong tide of national pride and independence set in, and there was less readiness to adopt anything Western. Progress therefore became slower, and there were many apostasies, chiefly from some American Missions regarded as lacking in orthodoxy. The bulk of the Protestant work all along has been American and non-Episcopal, and of the 40,000 Protestant converts three-fourths belong to churches founded by American missionaries. These are rapidly assuming a more or less national character; and similarly, the Anglican Missions have combined with the American Episcopal Church to form the *Nippon Sei-Kokwai*, or Japan Church, with a constitution and synod of its own, and 10,000 members; though for the present it has foreign bishops, four English and two American. The Russo-Greek Church has an important Mission in Japan, under an able bishop. It has enrolled some 25,000 converts. The Roman Church, which achieved such extraordinary success in the 16th century, is again to the front, having 54,000 Christians, about half of whom are the descendants of the small remnant left after the dreadful persecutions of that period. It has an arch-bishop and three bishops, and it works largely through orphanages, hospitals, &c., which methods have not been adopted by Protestant Missions in Japan, as they have been in India. A remarkable article in the *Illustrated Catholic Missions* for October and November 1900 states that while the Protestant Missions have gained many converts from among the educated classes, the Catholic Missions are most successful among the poor. The writer cites an intelligent Japanese as attributing this to the similarity of Roman and Buddhist ritual: educated men, despising the latter, are led to despise the former; but he himself attributes it rather to the fact that Protestantism is the religion of the nations which Japan regards as most progressive, Great Britain, Germany, and the United States. He considers, however, that the Catholic religion will eventually prevail, because it is embraced from "supernatural motives," while the Protestants, being swayed by private judgment, are more likely to become freethinkers.

THE REST OF EASTERN ASIA.—*Burma* is part of British India, although very different in many ways, and Buddhist in religion. The Society for the Propagation of the Gospel, the American Baptists, and the Roman Catholics have large and fruitful Missions there. *Siam* is a field of the American Presbyterians, also with promising fruit. In *French Indo-China* the Roman Missions are very extensive, and have 700,000 converts, notwithstanding violent persecution prior to the French occupation, with terrible massacres of priests and native Christians. The Pope in 1900 "beatified" many of the martyrs. *Mongolia* has been the scene of pioneer efforts by the London Society. In *Manchuria* the Scottish and Irish Presbyterians have had remarkable success, while the Roman year-book says that, despite Russian influence, the people "are throwing themselves *en masse* into the Catholic Church." This field has been called the Uganda of Asia. *Korea*, opened by Sir H. Parkes's treaty in 1883, has been occupied by American, Canadian, and Australian Presbyterians, and, since 1889, by the Society for the Propagation of the Gospel. The Roman Catholics had Missions there before the opening, and nine missionaries were martyred in 1866, while now there are 36,000 adherents. The *Philippine Islands* have already attracted missionaries from the United States.

THE SOUTH SEAS.—The great archipelagos of the Pacific are old and very fruitful fields of the English Congregationalists and Wesleyans and the Scottish Presbyterians. The Anglican Mission in *Melanesia* has been already mentioned. The *Sandwich Islands* and *Micronesia* are American fields. In the whole Pacific the Roman Missions count 85,000 converts. A more modern field is *New Guinea*. In the British part of that great island there are Missions of the London Society (1871), the Anglican Church of Australia (1892), and the Australian Methodists (1892)—all in the early stages of work.

NORTH AMERICA.—Missions among the Red Indian tribes in the North-West Territories of both the United States and Canada have long been carried on by several societies. Bishop Whipple of Minnesota was justly called the Apostle of the Indians, so far as the

work of the American Episcopal Church was concerned. In the Canadian North-West the Church Missionary Society's Missions have reached many tribes, up to the shores of the Polar Sea, and made some thousands of converts. Even the wandering Eskimo have supplied a few hundred members to the Christian Church. The one bishopric of those territories in 1872 has since become eleven. The Roman Catholic missionaries also are scattered over these immense territories, and have a large number of Indian adherents. Besides the Oblates before mentioned, many are Jesuits from French Canada. The Russo-Greek Church has a mission in Alaska, dating from the time when it was Russian territory. The total number of Indians in British North America is 99,000, of whom about 27,000 are still pagan, and the rest are about equally divided between the Protestant and Roman Catholic Missions.

CENTRAL AMERICA AND WEST INDIES.—American Missions are at work in Mexico and adjacent countries. In the islands the negro population has been reached by most of the larger British societies.

SOUTH AMERICA.—The South American Missionary Society, founded by the ill-fated Captain Allen Gardiner, has much extended its work among the Indians of the interior of what has been well called "the Neglected Continent"; and several American Missions are also at work. The Society for the Propagation of the Gospel has an important Mission in British Guiana. But there are numerous heathen tribes never yet reached. The Roman Church, which is dominant throughout the continent, has been engaged in serious struggles with the anti-religious tendencies of the Republican governments, and *L'Année de l'Église* makes no mention of Missions among the Indians. In fact, the Pope in 1897 was obliged to send a severe rebuke to the clergy for their lack of consistency and zeal.

The Christian Church bases its missionary enterprise upon the command of its Founder, and regards the duty as just the same whether the results be large or small. It appeals to common sense, saying in effect, "If it be a fact that a Divine Person came into the world to bless mankind, all men ought to know it, and have a right to know it. However much or (if you will) little a Buddhist or a Moslem may need to know of Christ, he certainly has a *claim* to be told of Him. The responsibility, if there be any, of believing, rests with the individual told; the responsibility of telling him rests with the Christian Church." On this view of the matter, results, however desirable, are no certain test of a Mission doing its work. A Mission in Persia, with its handful of converts, has, on this view, as much right to support and appreciation as a Mission in southern India with its tens of thousands. Again, on the hypothesis that Christianity is true, the statistics at a particular period are no test of success at all. For in them *the dead are not counted*; and the converts who are already dead are—at least in respect of individual salvation—the surest of results. If, however, we are to take statistical returns for what they are worth, it is estimated that the Christians in heathen lands gathered by Protestant Missions probably amount to four millions, and, as above stated, a similar total may be ascribed to Roman Catholic Missions, making eight millions in all. This, however, includes adherents still under instruction for baptism, and their children. The inner circle of communicant members is not more than one-third of the total.

But it has to be carefully borne in mind that Missions are still—to the reproach of the Christian Church on the above hypothesis—in their infancy. In most of the South Sea Islands, and among the Red Indians of North America, the work of evangelization, *i.e.*, of proclaiming the Gospel, may be said to have been fairly completed, but in the great continents of Africa and Asia it is as yet in an early stage. Meanwhile, it is generally acknowledged that a vast preparatory influence is being exercised. In effecting the mighty social changes in India since 1850, Lord Lawrence said that Christian Missions had done more than all other agencies combined. The forward movements in China (prior to the Boxer outbreaks) were largely the direct result of missionary influence. In Japan, leading men fully recognize the importance of that influence.

Results of missions.

In Africa, geographical exploration, commercial enterprise, and the extension of European power, have followed in the wake of missionary pioneers. While it is true that very diverse opinions are held concerning Missions, it is indisputable that the most favourable testimonies come from those who have really taken the most pains to examine and understand their work. The one discouraging feature, from the Christian point of view, is the backwardness of Christendom in its great enterprise. If the Churches did their foreign work with the same energy which they throw into their home work, the results would be very different.

Statistics of Protestant Missions.—A very elaborate volume of Protestant missionary statistics at the end of the 19th century has been compiled by Dr Dennis of America, and published in Great Britain by Messrs Oliphant, Anderson, and Ferrier. We take the following condensed figures from its tables:—

There are 558 missionary societies, viz:—	
Engaged in direct evangelization	294
Indirectly aiding the work	127
Devoted to specific branches of the work	137
	<u>558</u>

These societies have their headquarters in the following parts of the world:—

Great Britain and Ireland	154
European Continent	82
American Continents	128
Asia	117
Africa	42
Australasia and Oceania	35
	<u>558</u>

The total number of missionaries is stated to be 17,974, but the figure needs considerable reduction, and a more careful analysis gives the following approximate results:—

Ordained	4,800
Physicians: Men	480
Women	220
Laymen not physicians	2,000
Unmarried women not physicians	3,600
Married women not physicians	4,400
	<u>15,500</u>

The results of Missions, as represented by living native Christians, are thus given:—

Christian community—including communicants and non-communicants of all ages	4,514,592
Of whom are communicants	1,531,889
Increase of communicants in one year	112,152

The following educational statistics are given:—

Missionary universities and colleges	94
Theological and training schools	375
Boarding and high schools, &c.	879
Industrial training institutions	179
Medical schools	67
Elementary day schools	18,742
Pupils in the higher institutions—	
Males	97,667
Females	42,908
Total pupils—Males	716,741
Females	332,980

Philanthropic institutions:—

Orphanages	247
Leper homes, &c.	100
Homes for blind or deaf mutes	30
Miscellaneous	156
Guilds and associations	118

Medical statistics:—

Mission hospitals	379
" dispensaries	783
Hospital in-patients, in year	85,169
Individual patients, in year	2,347,780
Total treatments, in year	6,442,427

Literary statistics:—

Missionary Bible translations—	
Of the whole Bible	99
Of the New Testament	121
Of portions	236

Carried forward 450

Brought forward	456
Add transliteral versions	20
	<u>476</u>
Deduct obsolete versions	40
	<u>436</u>
Versions in use	436
	<u>436</u>
Mission publishing houses and printing-presses	159
Periodicals issued by missionaries	379

Mississippi, one of the southern states of the American Union, situated south of the state of Tennessee, and immediately east of the Mississippi river. It is separated from Tennessee by 35° N. approximately. The 31st parallel forms its southern boundary from the Mississippi river to the Pearl, and the Gulf of Mexico marks its limits from the mouth of this river to the arbitrary line which separates Mississippi from the state of Alabama on the east. The islands within 6 leagues of the coast are included, and the total land area of the state is 46,383 square miles. The state was organized in 1817.

Population.—The census figures have been as follows:—

	Total.	White.	Coloured.	Density per square mile.
1880	1,131,592	479,371	652,221	24.42
1890	1,289,600	544,851	744,749	27.57
1900	1,551,270	642,900	908,370 ¹	33.48

¹ Including a small number of Chinese and Indians.

The rate of increase from 1890 to 1900 was 20.3 per cent., as compared with 14.0 per cent. for the preceding decade. The census of 1900 showed 781,451 males and 769,819 females, 1,543,289 native-born and 7981 foreign-born inhabitants. The proportion of whites to the total in 1880 was .423, in 1890 .424, and in 1900 .415. There are about 2200 Indians of the Choctaw tribe still remaining scattered through the central parts of the state. In 1900 there were seven cities and towns having a population of more than 5000 inhabitants each, and an aggregate population of 68,503, and of these only three had a population of over 8000. The urban population was therefore 2.6 per cent. of the total number of inhabitants. The population of the chief cities was, in 1900, Vicksburg, 14,834, Meridian, 14,050, Natchez, 12,210. The population has grown in the last decade of the 19th century chiefly by natural increase.

Education.—Interest in education has been greatly increased, and the public schools have made decided advances. The total number of persons of school age, including all between the ages of 5 and 21 years, in 1900 was 588,275. Of these 167,178 were white and 192,368 coloured. In 1900-01, 387,488 pupils were enrolled in the public schools: The total number of teachers employed was 8515, 5147 white and 3368 coloured. The cost of maintaining these schools, not including the higher institutions, was \$1,472,432. The length of the public school term averages 4½ months. Separate schools of all grades are maintained for the two races, affording equal facilities. The State University, near Oxford, has an academic department, and schools of law, engineering, &c. There are 20 instructors and 300 students. Its endowment amounts to \$750,000, besides equipment worth \$300,000. Its annual income is \$50,000. Its endowment comes from the sale of lands given by Congress in trust to the legislature of the state for this use. The State Agricultural College has revenues amounting to \$55,000, about 20 instructors, and 300 students. The Industrial Institute and College for Girls has an income of \$30,000, and 400 students. These institutions are for white youth. There are corresponding institutions for coloured youth maintained by the state. In all state institutions tuition is free. The number of private schools and endowed colleges, other than state, is small.

Charitable and Penal Institutions.—The state supports two hospitals for the insane, one at Jackson, with 900 patients, and one at Meridian, with 312. It maintains two hospitals, one at Vicksburg and one at Natchez, and schools for the blind and for deaf mutes at Jackson. All of these have liberal provision for support. The state has adopted the policy of keeping the convicts condemned to the state prison at work on farms leased or owned by the state. Under this system abuses have been avoided, eminently humane treatment has been secured, and convict labour in agriculture, chiefly in the raising of cotton, has been quite profitable. The management is under a board of control, consisting of the governor of the state, the attorney-general, and the three railroad commissioners.

Religion.—The chief religious denominations are branches of the Methodists, Baptists, and Presbyterians, having numerical strength in the order named. The population is largely religious.

Agriculture.—Agriculture is the occupation of a very large proportion of the people. Cotton is the chief market crop. The production amounts to about 1,000,000 bales of 500 lb each, the value of which is from \$40,000,000 to \$50,000,000. The state grows enough grain and hay for domestic use. Stock-raising, particularly the raising of cattle, is an important and growing industry. The southern third part of the state is covered with a heavy growth of yellow pine, representing a value of \$250,000,000. The useful timber of other varieties aggregates in value more than this amount. Clays and marls are mined to a small extent. Borings to a depth of from 200 to 500 feet in nearly every county yield an abundance of pure water.

Manufactures.—The following table shows the manufacturing and mechanical industries in 1890 and 1900, with the percentage of increase for the decade:—

	1890.	1900.	Percentage of Increase.
Number of establishments	1,698	4,772	181.0
Capital	\$14,896,884	\$35,807,419	140.4
Wage-earners, average number	14,465	26,418	82.6
Total wages	\$4,191,754	\$7,471,886	78.3
Cost of material used	\$10,064,897	\$21,692,092	115.5
Value of products	\$18,705,834	\$40,431,386	116.1

The manufacture of lumber, of cotton goods, and of cotton-seed products are the chief industries, and are profitable.

Railways.—The chief railway lines are the Illinois Central and its branches, the Mobile and Ohio, the Southern, and the Louisville and Nashville. The total mileage is 2681. These lines repre-

sent a value of about \$10,000 per mile. The maritime interests are confined to fishing boats on the coast, where oysters are taken in great quantity for packing. The commercial business is transacted largely through cities in adjoining states, chiefly New Orleans, Mobile, and Memphis.

Internal Improvements.—Under state management a complete system of embankments, or levees, has been completed along the east bank of the Mississippi river from the northern boundary of the state southwards to the vicinity of Vicksburg. These have in the main been efficient in preventing the river from overflowing the rich delta lands situated between the Mississippi and the Yazoo, thus rendering available for agriculture thousands of acres of the most fertile soil. The new capitol building at Jackson will cost at least \$1,000,000.

Finances.—The total valuation of property, from assessment rolls, was in 1899: Realty, \$113,210,931; personal property, \$74,606,004. The state debt was \$2,666,048, of which \$1,030,946 is payable, and the balance, \$1,635,102, represents trust funds for educational purposes, derived from the sale of lands granted by Congress for these purposes.

Banks.—There are 12 national banks; aggregate capital, \$780,000; deposits, \$2,725,391. There are 107 private banks, with capital amounting to \$646,584 and deposits amounting to \$11,349,618. There are nine building and loan associations.

History.—Since 1880, and especially during the last decade of the 19th century, the attention of the people has been given to the intellectual, moral, and material advancement of the state. The white race has been dominant in politics since 1875. The legislation passed since that time marks a distinct advance and betterment for all classes. High licence and prohibitory legislation make the sale of intoxicants illegal in all counties except fourteen. The law regulating distribution of school funds gives decided advantages to the counties where blacks largely predominate, and allows in those counties a term of from seven to nine months. The white population pays nine-tenths of the school tax. Railways are required to furnish separate and equally good accommodation for white and coloured passengers. Legislation amply protects the labouring classes in their rights. Liberal inducements in the way of exemption from taxation are offered to investments in manufactures, and full protection is afforded to vested capital. The Constitutional Convention of 1890 changed the organic law in several important particulars. Elections are by secret ballot, each voter marking without assistance the names of the persons voted for. "Every male inhabitant of this state, except idiots, insane persons, and Indians not taxed, who is a citizen of the United States, twenty-one years old and upwards, who has resided in this state two years, and one year in the election district, or in the incorporated city or town in which he offers to vote, and who is duly registered as provided in this article, and who has never been convicted of bribery, burglary, theft, arson, obtaining money or goods under false pretences, perjury, forgery, embezzlement, or bigamy, and who has paid, on or before the 1st day of February of the year in which he shall offer to vote, all taxes which may have been legally required of him, and which he has had an opportunity of paying according to law, for the two preceding years, and who shall produce to the officers holding the election satisfactory evidence that he has paid said taxes, is declared to be a qualified elector; but any minister of the Gospel in charge of an organized church shall be entitled to vote after six months' residence in the election district, if otherwise qualified." (Constitution of 1890, sec. 241.) It is also provided that a uniform poll tax of two dollars, to be used solely in aid of the common schools, shall be imposed on every male inhabitant between the ages of twenty-one and sixty years. Electors must be duly registered at least four months before any election in which they may offer to vote, and "every elector shall, in addition to the foregoing qualifications, be able to read any section of the Constitution of this state; or he shall be able to understand the same when read to him, or give a reasonable interpretation thereof." Elections for state and county officers occur every four years. The governor, state treasurer, state auditor, county sheriffs and treasurers, and certain other officers are not eligible for immediate re-election. Corporations can be formed under general laws only. Property rights of married women are fully protected. While the new qualifications for voting have barred from the polls many illiterates of both races, the state has since 1880 been offering equal school facilities to all, and ample opportunity for becoming qualified. The careful restrictions placed upon the use of the ballot have excluded chiefly unworthy and inconsiderate voters. These laws have evidently allayed political excitement, and promoted among the labouring classes attention to private business and the means afforded for education. The accumulation of property by these classes has been greater during the last decade of the 19th century than during any equal preceding period. This legislation has gone far towards solving the problem of the satisfactory co-existence of the white and black races in the state.

(R. B. F.)

Mississippi River.—A general account of the Mississippi river and of its valley is given in the earlier volumes (ninth edition) of this work (vol. xvi. pp. 518–521). We are here concerned with the history of the improvement works which have been carried out in it since 1880.

The distance from St Paul to St Louis, by the river, is 698 miles. On this portion an attempt is being made to obtain at least $4\frac{1}{2}$ feet of water at all stages, from St Paul to the Missouri river, and 6 feet thence to St Louis. Below St Paul the low-water depths were sometimes not more than 2 feet. The usual methods for regulating rivers are followed: lateral channels are closed, excessive widths are reduced by spurs and closing side channels, caving banks are protected, and dredging is used. At Des Moines a ship canal, with locks, has been built to avoid the rapids, and at Rock Island a channel has been cut in the rock. From St Louis to Cairo, at the mouth of the Ohio, the Mississippi carries all the sediment from the Missouri, at the mouth of which it changes from a clear to a muddy stream. In contraction works here, accordingly, hurdles of piles and brush are used instead of the solid spurs of the upper river. They have had surprising results in building up new banks. Caving banks have been protected by mattresses similar to those used on the lower river, but, partly on account of lesser depths of water, much lighter mattresses can be used. Two pumping dredges with a capacity of 1000 cubic yards of sand per hour have been built, with which it is hoped to maintain low-water depths of 6 feet instead of $3\frac{1}{2}$ or 4 feet. The depth ultimately desired is 8 feet. Above Cairo there had been expended, under the present projects for improving the river, about \$17,000,000 up to 1898.

Of the tributaries to the Mississippi, the Ohio is commercially the most important, as it carries coal from Pittsburg to all points below. Works for its improvement, on the same general principles as those for the Upper Mississippi, have been going on for many years, the aim being to get 6 feet of water at low stages. This is impracticable immediately below Pittsburg (1000 miles above the mouth of the Ohio), on account of the small low-water flow. Accordingly locks and movable dams are being constructed to give navigable pools during low water. Six have been completed or are in course of construction, and Congress has required an estimate for twelve more, carrying the system down to Marietta. Each lock and dam costs about \$800,000.

The Lower Missouri river has a slope nearly double that of the Mississippi below Cairo; its low-water flow may sink to $\frac{1}{4}$ part of its high-water flow, or to 15,000 cubic feet per second: its average sediment for one year was $\frac{2}{3}$ part by weight of the water, rising to a maximum of $\frac{3}{5}$ part. A good deal of money has been spent in attempting to improve it by works of regulation, but, as might be expected in a river of such characteristics, with limited success.

The principal expenditure for the improvement of the Mississippi river below Cairo has been since 1879 under the control of the Mississippi River Commission, the jurisdiction of which extends from Cairo to the head of the passes, a distance of 1060 miles by the river. The plan adopted by the commission was that usually followed on such rivers, namely, to protect the banks when caving existed or was to be feared, and to build contracting works when the widths exceeded about 3500 feet and the low-water navigation was difficult. The low-water depths were sometimes $4\frac{1}{2}$ or 5 feet; it was proposed to obtain 10. In addition the use of levees was adopted as an important part of "any general and systematic plan for the improvement of the river and the prevention of destructive floods."

In protecting the banks, mattresses of brush or small trees, woven like basket-work, were sunk on the portion of the bank at the time under water, by throwing rubble stone upon them, an excess of stone being used. A common size of mattress was 800 feet long, counted along the bank, by 250 feet wide. Sometimes a width of 300 feet was used, and lengths have reached 2000 feet. The depth of water was often from 60 to 100 feet. At first these mats were light structures, but the loss of

large quantities of bank protection by the caving of the bank behind them, or by scour at their channel edges, forced the commission steadily to increase the thickness and strength of the mattress, so that the cost of the linear foot of bank protection, measured along the bank, rose from \$8 or \$10 to \$30 in the later work. The structure of the mattress was also changed, so that its longitudinal strength became that of the strands of wires which replaced the binding poles formerly used, and its thickness that of the fascines which replaced the brush. Even in the stronger types of bank protection there have been failures, and the permanence of the present type is not fully assured. At first the portion of bank out of water was graded to a gentle slope and then covered by a mattress built in place; later, rubble stone was used instead, and was much more satisfactory. When stone is costly, as on the lower river, concrete slabs have been experimented with, both for the upper bank and for sinking mattresses.

The contraction works adopted were systems of spurs or pile dykes, running out from the shore nearly to the line of the proposed channel. Each dyke consisted of from one to four parallel rows of piles, the interval between rows being about 20 feet, and between piles in a row 8 or 10 feet. The piles and rows were strongly braced and tied together, and in many cases brush was woven into the upper row, forming a hurdle, in order further to diminish the velocity of the water below the spur. At Baleshed, 540 miles below Cairo, an area of 700 acres was built up 20 feet in a few years by such spurs. Similar dykes were used to close waterways behind islands. This system of contraction works and bank protection was applied to two stretches of the river. The first, at Plum Point, 165 miles below Cairo, was 18 miles long, and was carried well towards completion, the navigable depths being increased from a minimum of 5 feet to 9 or 10 feet in ordinary seasons. The second, at Lake Providence, 542 miles below Cairo, was 19 miles long, and was not nearly completed. At one time a prohibition by Congress of the use of bank revetment, followed by a lack of funds, led to a large loss of work caused by changes in the river. By 1893 there had been expended at Plum Point \$3,600,000, and at Lake Providence \$3,200,000. It was evident that the cost of the proposed improvement, which had been estimated at \$33,000,000 by a majority of the commission in 1881, would really be several times that amount, and that the works would require heavy expense for their maintenance and many years for their execution. Navigation interests demanded more speedy relief.

The commission then began building powerful pumping dredges, and in 1900 had nine in operation. Centrifugal pumps are used, the suction pipes being at the bow and the discharge at the stern through a line of pipes about 1000 feet long, supported on pontoons. Water jets or cutters stir up the material to be dredged before it enters the suction pipes. The largest of the dredges had two entirely independent pumps, each having discharge pipes 33 inches in diameter. Its engines had 2000 horse-power. During test trials its average delivery of sand was 4920 cubic yards per hour. It cost \$217,000. The later dredges, of a more convenient size, have a capacity of about 1000 cubic yards of sand per hour, the velocity in the 32- to 34-inch discharge pipes being from 10 to 15 feet per second. They cost from \$86,000 to \$120,000, and their working during a low-water season costs about \$20,000. These dredges begin work on a bar where trouble is feared before the river reaches its lowest stage, and make a cut through it. A common cut is 2000 feet long by 250 feet wide, and 3 or 4 feet deep. They have rendered much service to navigation, and the aim now is to maintain with them low-water navigable depths of 9 feet.

In 1882 occurred one of the greatest floods known on the Mississippi, and extensive measurements of it were made. A maximum flood of 1,900,000 cubic feet per second crossed the latitude of Cairo. Much of it escaped into the bottom lands, which are below the level of great floods, and flowed through them to rejoin the river below. The flow in the river proper at Lake Providence, 542 miles below Cairo, was thus reduced to about 1,000,000 feet per second, while if the river had been confined by levees, the flow between them would have been double, or about 2,000,000 cubic feet per second. The volume of the levees in 1882 was about 33,000,000 cubic yards, and by 30th June 1899 had been increased to about 137,000,000 cubic yards, of which the United States has built about one-half, and has expended on them about \$14,000,000. The length of levees is about 1400 miles, and, with the exception of a gap of about 50 miles of broken levees on the west bank below Memphis, is continuous, save where interrupted by tributaries or by high lands, from New Madrid, or 80 miles below Cairo, to Fort Jackson, 1039 miles below Cairo. The width of the interval between levees on the opposite banks of the river varies greatly; in many places the levees are built much nearer the normal margin of the river than is consistent with keeping the flood heights as low as possible. This has arisen from two causes: firstly, to give protection to lands already cultivated, which lie usually near the bank of the river; secondly,

to avoid the lower ground, which, owing to the peculiar formation, is found as one goes back from the river. Another ill result of this nearness of the levees to the bank of the river is the loss of levees by caving, which was over 4,000,000 cubic yards in 1898-99, and can only be prevented by bank protection costing \$150,000 per mile, to protect a levee perhaps 16 feet high costing about \$30,000 per mile. The levees have top widths of 8 feet, side slopes of $\frac{1}{2}$, and banquettes when their heights exceed about 10 feet. The grades of the levees are usually 3 feet above the highest water, and have to be raised from year to year as greater confinement of water gives greater flood heights. When this system is completed, there will probably be hundreds of miles of levee with heights exceeding 14 feet. In 1883 a majority of the Mississippi River Commission estimated the cost of a system of levees from Commerce, Missouri, 38 miles above Cairo, to Fort Jackson, 1039 miles below Cairo, at \$11,443,000. In 1899, after about \$28,000,000 had been spent on levees by the United States and by the local authorities, the commission submitted an estimate for additional work on levees, amounting to 124,000,000 cubic yards and costing \$22,000,000. The effect of the levees has been to increase flood heights. A conspicuous example is that on Lake Providence, where the maximum gauge heights since 1879 have risen from 38·3 feet in 1882 to 44·5 in 1897, or by 6·2 feet. Captain Newcomer, the local engineer, estimates that perfect confinement of the water will increase this maximum gauge reading to 49·5, a total increase of 11·2 feet. Though the Mississippi River Commission was forbidden by Congress to build levees to protect lands from overflow, a majority of its members believed them useful for the purpose of navigation improvement. Since 1882 no less than \$28,000,000 has been expended on levees. This enormous expenditure has effected no sensible improvement in the navigation of the river at low stages, and at other stages no improvement was needed for the purposes of navigation. About \$37,000,000 has been appropriated for the commission work below Cairo since 1879.

In 1879 Mr J. B. Eads, the contractor for the South Pass jetties, obtained a channel through the pass having a depth of 30 feet, the original depth on the bar having been 9 feet, and thus earned his final payment for the jetties. He used essentially the plan of a Government board of engineers, on which Congress gave him the contract, without competition. His original contract was for a channel 30 feet deep and 350 feet wide, but Congress subsequently removed this restriction on the width without making a corresponding reduction in the price. The works were required to be "permanent works by which said channel may be maintained for all time after their completion." He was entitled by law to \$100,000 per annum for maintenance of a channel 26 feet deep and 200 feet wide through the jetties, and a central depth of 30 feet, and of 26 feet deep through the pass, until 1901. By the aid of dredging, this channel has thus far, with interruptions, been maintained; but these interruptions were for 174 days in 1897, and 63 days in 1898. In 1891 a crevasse occurred about 2 miles from the head of South Pass, from Pass à l'Outre to the gulf, and gradually increased until it was 2000 feet wide in 1894. The contractor's heirs made repeated efforts to close it, but in vain, and now the United States has undertaken the work. This crevasse, by lowering the water surface at the head of South Pass, diminished the flow through the pass, which has decreased somewhat in size. At the sea end of the jetties delta-building has gone on, so that dredging has been needed there. Of the curves of depth at the sea end of the jetties, the 60, 70, 80, 90, and 100 feet curves each advanced, between 1877 and 1897, from 92 to 108 feet annually, and the 40 and 50 feet curves advanced respectively about 52 and 62 feet. The difficulties in the South Pass have led Congress to require a plan to be made for improving the South-West Pass, which is much longer, and where the delta-advance at the sea end is much more rapid.

See the Annual Reports of the Chief of Engineers, U.S.A., since 1879.

(C. B. C.)

Missolonghi or Mesolonghi, a city of Greece, on the north side of the Gulf of Patras, about 7 miles from the coast. It is the chief town of the province of Acarnania and Ætolia. Population about 10,000.

Missoula, a city of Montana, U.S.A., capital of Missoula county, on Clark fork of the Columbia river, at the mouth of the Bitter Root, in the western part of the state, at an altitude of 3197 feet. It is on the main line of the Northern Pacific railway, at the junction of a branch from the Bitter Root valley, and is situated in the level valley, on which the town is regularly laid out. It is the seat of the University of Montana, a

non-sectarian institution, founded in 1895. In 1899 this had 12 instructors and was attended by 208 students, of whom 108 were women. Near it is the United States military post of Fort Missoula. Population (1890), 3426; (1900), 4366, of whom 1020 were foreign-born and 34 were negroes.

Missouri, a central state of the American Union, lying between about 36° and 40° 30' N. and 89° 2' and 95° 44' W. Its population in 1890 was 2,679,184, or 39 persons to the square mile. The native-born population in 1890 was 2,444,315; the foreign-born, 234,869. 51·7 per cent. of the population were males. The white population by the same census was 2,528,458, and the coloured, 150,726. There were, in 1890, 705,718 persons entitled to the privilege of voting. The population of the state in 1900 was 3,106,665, giving a density of 45·2 to the square mile, and was made up as follows:—1,595,710 (51·4 per cent.) were males and 1,510,955 (48·6 per cent.) females; 2,890,286 native-born and 216,379 (7·0 per cent.) foreign-born; 2,944,843 were white and 161,822 (5·2 per cent.) coloured, of whom 161,234 were negroes, 449 Chinese, 9 Japanese, and 130 Indians. The death-rate in 1900 was about 12·25 per cent. The urban population, classing as such all persons in cities of 8000 inhabitants or over, was 955,563, or 30·8 per cent. of the total population, as against 26·3 per cent. in 1890. St Louis, the chief city, had in 1880 a population of 350,518; in 1890, 451,770; and in 1900, 575,238. Kansas City, on the western border, next in importance, had in 1880 a population of 55,785; in 1890, 132,716; in 1900, 163,752. St Joseph, in the north-west, had in 1880, 32,431; in 1890, 52,324; in 1900, 102,979. Hannibal, in the north-east, had in 1880, 11,074; in 1890, 12,857; in 1900, 12,780. Springfield, a thriving railway centre in the south-west, had in 1880, 6522; in 1890, 21,850; in 1900, 23,267. Joplin, in the extreme south-west, in the centre of a lead and zinc mining district, had in 1880, 7038; in 1890, 9943; and in 1900, 26,023.

Agriculture.—All the chief cereals, all varieties of fruits, and all varieties of grass are found in abundance. Horses and mules are raised, and the mule market of St Louis is visited by purchasers from every part of the world. For 1899 the cereal products were reported to be as follows: corn, 162,915,064 bushels; wheat, 11,398,702 bushels; and oats, 20,709,000 bushels. A large crop of tobacco is also raised, that for 1899 being estimated at 7,580,000 lb. The fruit crop for 1899 was valued at \$19,500,000. The total number of farms in the state in 1890 was 238,043, with an aggregate acreage of 30,780,290, and a valuation of \$109,751,024.

Minerals.—Coal and iron are found in large quantities, as also are clays for fire-brick, marbles, limestone, and sandstone. The most important minerals of late years have been the immense deposits of lead and zinc in the southern and south-eastern sections, the richest of which lie in the counties of Jasper and St François. The output for the year ending 30th June 1899 was 70,829 tons of lead ore, and 181,430 tons of zinc ore, the total valuation of both being \$9,120,861. A large increase is made yearly in the lead and zinc product, especially from the south-western part of the state, and the area of mining lands is being greatly extended.

Commerce.—The commerce centres at St Louis in the east and Kansas City in the west. Trade with the south-west and with Mexico has made great strides since 1880. Foreign shipments of flour and grain by railways and river during 1899 were: flour, 743,373 barrels; wheat, 1,006,840 bushels; corn, 12,285,515 bushels; oats, 360,697 bushels. The total amount of freight received at St Louis by rail and river in 1899 was 15,272,482 tons, and the total amount shipped was 8,469,598 tons. The shipments of cotton for 1899 showed 377,513 bales exported, while 612,446 bales went to various parts of the United States. The total value of the gross receipts of cotton for the year was about \$15,000,000. Among other receipts at the St Louis market for 1899 were: lumber and logs, 1,148,124,000 feet; wool, 28,491,625 lb; sugar, 204,322,225 lb; coal, 109,067,875 bushels; butter, 13,729,188 lb.

Banks.—There were, in 1898, 494 banks incorporated under the state law. There were also 85 private banks and 70 national banks. The total resources of the banks in the state amounted to \$117,009,314, distributed as follows: loans and discounts, \$76,161,897; overdrafts by solvent customers, \$771,803; U.S. bonds and other bonds and stocks, \$6,292,472; real

estate, including banking-house, \$3,408,262; furniture and fixtures, \$578,383; due from other banks, \$17,872,944; cheques and other cash items, \$1,816,523; U.S. notes of various kinds, \$6,092,722; gold coin, \$3,201,406; silver and other small coin, \$669,421; all other resources, \$143,476. The St Louis bank clearings for 1899 reached a total of \$1,638,348,203, a gain of more than 65 per cent. in ten years.

Manufactures.—The general statistics of manufactures in 1890 and 1900, with the percentages of increase during the intervening decade, are given in the following table:—

	1890.	1900.	Per cent. Increase.
Number of establishments	14,052	18,754	33.5
Capital	\$189,558,546	\$249,888,581	31.8
Salaried officials, clerks, &c.	18,936 ¹	13,900	26.6 ²
Salaries	\$16,773,935 ²	\$14,569,606	13.1 ²
Wage-earners, average number	124,203	134,975	8.7
Total wages	\$59,643,429	\$60,719,429	1.8
Miscellaneous expenses	\$22,885,565	\$41,396,905	80.9
Cost of materials used	\$177,582,382	\$214,988,018	21.1
Value of products	\$324,561,993	\$385,492,784	18.8

A brief summary of the statistics of thirteen leading industries follows:—

Industry.	Number of Establishments.	Capital.	Value of Products.
Boots and shoes	50	\$4,183,979	\$11,253,202
Carriages and waggons	377	4,019,087	5,583,364
Cars (steam railway) and general shop construction and repairs by steam railway companies	47	8,176,242	14,246,889
Clothing, men's, factory product	148	4,651,882	8,925,088
Coffee and spice, roasting and grinding	27	2,517,482	5,266,264
Confectionery	99	2,842,164	5,554,384
Flouring and grist-mill products	1145	11,402,827	26,393,928
Foundry and machine-shop products	261	11,606,445	15,073,005
Lumber and timber products	1197	11,089,799	11,177,529
Malt liquors	49	25,731,930	13,776,905
Printing and publishing (including newspapers and periodicals)	1100	11,149,288	15,355,949
Slaughtering and meat packing (wholesale)	31	7,844,054	42,229,127
Tobacco and snuff	602	8,011,237	27,847,432

The three most important manufacturing centres are St Louis, Kansas City, and St Joseph, in the order named. The products of the first named amounted in value to more than 60 per cent. of the total products of the state. As the foregoing table shows, the most important industry in the state is slaughtering and meat packing; during the decade 1890-1900 the value of its products increased nearly 135 per cent. St Joseph is the principal centre of manufacture for this industry, and St Louis ranks next.

Railways.—Several important trunk lines of railway afford ample accommodation for passenger and freight traffic. Chief among these are the Missouri Pacific; the Iron Mountain; the St Louis and San Francisco; the Wabash; the Chicago, Burlington, and Quincy; the Atchison, Topeka, and Sante Fé; the St Louis South-Western; the Missouri, Kansas, and Texas; and the Kansas City, Fort Scott, and Memphis. The total mileage of railways in Missouri in June 1898 was 6762.56.

Finance.—The financial condition of the state, as shown in a statement prepared by the state auditor, 4th January 1900, is as follows:—

Total valuation of real estate and personal property, as fixed by the State Board of Equalization for 1899 taxes	\$987,456,906
Railway, bridge, and telegraph property, including street railway property for 1899 taxes	102,946,600
Merchants and manufacturers, valuation for 1899 taxes (estimated)	55,125,824
Total	\$1,145,529,330

¹ Includes proprietors and firm members, with their salaries.

² Decrease.

Balance in treasury, 31st December 1898	\$897,109
Receipts into the state treasury from all sources, for all purposes, for the year ending 30th December 1899	4,370,249
Expenditure during 1899, for all purposes	4,690,351
Balance in treasury, 30th December 1899	577,007

State Bonded Debt, 1st January 1900.

5 3½ per cent. 5-20 refunding bonds, due 1st July 1907	\$5,000
5 3½ per cent. 5-20 refunding bonds, due 1st October 1907	5,000
2837 3½ per cent. 5-20 refunding bonds, due 1st January 1908	2,837,000
Total bonded debt	\$2,847,000

School and Seminary Certificates of Indebtedness.

School certificates, 6 per cent.	\$2,909,000
School certificates, 5 per cent.	249,000
Seminary certificates, 6 per cent.	\$122,000
Seminary certificates, 5 per cent.	1,113,839
Total	\$1,235,839

The rate of taxation in 1898 was 25 cents on every \$100 of the valuation.

Education.—Since 1880 the state university at Columbia, having lost its old buildings by fire, has erected new and commodious structures. Its endowment has been increased, its faculty enlarged, and its standard of scholarship raised. The high schools have felt the impulse of the new life of the university, and about 100 of these schools are now able to prepare their pupils for admission to its classes. The number of students enrolled at the university in January 1900 was 1000; the number of instructors 65. Washington University, a non-sectarian endowed institution in St Louis, has increased its endowment funds by nearly \$4,000,000, has purchased a tract of 150 acres for a new site, and is erecting new buildings at an immediate cost of \$800,000. The number of students during 1899-1900 was 645, of instructors 99. The St Louis University is the oldest and most influential of the Roman Catholic institutions. It was established in 1829, and is controlled by the Order of Jesuits. It occupies a group of commanding buildings, erected at a cost of about \$1,000,000. The faculty of government and instruction numbers 25. Other colleges and schools, founded in the interests of various religious bodies, are increasing in strength and influence. The net amount of state school moneys apportioned to the use of the public schools in 1898 was \$915,866, and the state school enumeration was 980,422, with 15,259 teachers. The percentage of illiterates is 9.5. In 1900 the number of persons of school age (5 to 20 years inclusive) was 1,105,258. Out of 856,684 males of voting age, of whom 46,418 were negroes, 60,327 were illiterate (unable to write), of whom 14,829 were negroes.

Penal and Charitable Institutions.—The state penitentiary is situated at Jefferson City, the capital. On 1st January 1901 it contained 2116 convicts. Other state institutions are an insane hospital at Fulton, with 566 patients in 1896; one at St Joseph, with 714 inmates; and another at Nevada with 466. There are also the following schools: (1) the Missouri school for the blind, at St Louis, with 116 scholars; a school for the deaf and dumb at Fulton, with 392 scholars; a reform school for boys at Boonville, with 160 boys; a reform school for girls at Chillicothe, with 63 girls.

Religion.—The Roman Catholic Church was, for many years after the early settlement of the state, the only religious organization. Many Protestant bodies, however, now share with that Church in the religious work of the state. In 1896 the number of communicants in the leading denominations was reported as follows: Roman Catholics, 160,000; Methodists, 160,000; Baptists, 150,000; Disciples of Christ, 95,000; Presbyterians, 50,000; Lutherans, 25,000; Episcopalians, 6406. Denominational colleges are supported by most of these sects.

Politics.—Missouri has given a large plurality to the Democratic candidate at every Presidential election since 1872. The vote for President for the elections specified was given as follows:—

1888, Democratic,	261,974	Republican,	286,257
1892 "	268,398	"	226,918
1896 "	363,667	"	304,940
1900 "	351,912	"	314,091

The vote of St Louis in 1896 was: for Bryan (Democrat), 50,091, and for McKinley (Republican), 65,708; in 1900, for the same candidates, 59,931 and 60,697 respectively. No important changes have been made in the state constitution since 1875, when the

present constitution was drawn up by a convention called for that purpose, and was ratified by the people. (M. S. S.)

Missouri River, the main western branch of the Mississippi river, U.S.A. It rises in three streams in the Rocky Mountains of south-western Montana, the Jefferson, Madison, and Gallatin rivers, which unite at the foot of Gallatin Valley; thence the river flows north, out of the mountain region into the plains, which it traverses in a course at first north-east, then east, flowing down the general slope. Entering North Dakota the river turns gradually to the south-east, then south, and again south-east, traversing both North and South Dakota. It forms the eastern boundary of Nebraska and part of Kansas, and crosses Missouri in an easterly course to its junction with the Mississippi a few miles above St Louis. Its entire length is 3475 miles, and it drains an area of 527,155 square miles, or more than one-sixth of the area of the United States, excluding Alaska. As its longest and largest affluent, it is properly the main source of the Mississippi. Of the three sources of the Missouri, the middle stream, Madison river, rises in Yellowstone National Park, and is fed by geysers and hot springs. Yellowstone river, a right-hand tributary, rises just south of Yellowstone National Park, flows through it, and joins the Missouri at the eastern boundary of Montana. On this stream, within the park, are Yellowstone Lake, the Great Falls (300 feet high), and the cañon, features which constitute some of the finest scenery of the United States. In the Dakotas many small but long streams join it, among them the Little Missouri from the Bad Lands, and the Cheyenne from the Black Hills. In Nebraska come the muddy waters of the Platte, which rises in two large branches in Colorado. At Kansas City the Missouri is joined by Kansas river, a stream of the plains. On the left the Missouri is fed by Sun, Marias, and Milk rivers, which rise in Mission Range in western Montana, and farther down by the James, the Big Sioux, and many smaller streams. Owing to the vast amount of detritus which its waters collect in its long course over the plains, the Missouri is at all times thick with mud, and well deserves its familiar cognomen of "Big Muddy." The Missouri is navigable at high water to the Great Falls, near the city of that name in Montana; and even now, in spite of the competition of the railroads, carries a large amount of freight. Upon it are situated many cities, the principal of which are Kansas City, Mo., St Joseph, Mo., and Omaha, Neb. (H. G*.)

Mistral, Frédéric (1830—), Provençal poet, was born at Maillane (Bouches-du-Rhône) on 8th September 1830. In the autobiographical sketch prefixed to the *Isco d'Or* (1876) he tells us, with great simplicity and charm, all that is worth knowing of his early life. His father was a prosperous farmer, and his mother a simple and religious woman of the people, who first taught him to love all the songs and legends of the country. In these early days on the farm he received those first impressions which were destined to constitute one of the chief beauties of *Mirèio*. "Mon enfance première se passa donc à la ferme, en compagnie des laboureurs, des faucheurs et des pâtres. Je me souviens toujours de cette époque avec délices. . . ." In his ninth year Mistral was sent to a small school at Avignon, where he was very wretched at first, regretting the free outdoor life of the country. Gradually, however, his studies attracted him, above all the poetry of Homer and Virgil; and he translated the latter's first eclogue, showing his efforts to a young schoolfellow, A. Mathieu, who was destined to play a part in the foundation of the Félibrige. When Roumanille (see PROVENÇAL LITERATURE, MODERN) be-

came an usher at Mistral's school, the two, fired by the same love of poetry and of their native Provence, soon became close friends. "Voilà l'aube que mon âme attendait pour s'éveiller à la lumière," he exclaimed, on reading Roumanille's first dialect poems; and he goes on to say: "Embrasés tous les deux du désir de relever le parler de nos mères, nous étudîâmes ensemble les vieux livres Provençaux, et nous nous proposâmes de restaurer la langue selon ses traditions et caractères nationaux." On leaving school (1847) he returned to Maillane, where he sketched a pastoral poem in four cantos (*Li Meïssoun*). With all his love for the country, he soon realized that life on a farm did not satisfy his ambition. So he went to study law at Aix, where he contributed his first published poems to Roumanille's *Li Prouvençalo* (1852). He had become *licencié en droit* the year before, but now decided on a literary career. The Félibrige was founded in 1854, and five years later appeared *Mirèio*, the masterpiece not only of Mistral, but so far of the entire school. It was everywhere hailed with enthusiasm: Lamartine wrote a panegyric on it, Gounod set its theme to music, and several translations appeared. The tale itself was nothing—the old story of a rich girl and her poor lover, kept apart by the girl's parents. Mireille, in despair, wanders along a wide tract of country to the church of the Trois-Maries, in the hope that these may aid her. But the effort was too great: she sinks exhausted, and dies in the presence of her stricken parents and her frenzied lover. Into this simple web Mistral has woven descriptions of Provençal life, scenery, character, customs, and legends that raise the poem to the dignity of a rustic epic, unique in literature. Nothing is forced: every detail is filled into the framework of the whole with a cunning which the poet was never again to attain. In the first lines he invokes Homer; and the Greek nature of his epic has been dwelt on by all its critics, from Lamartine to Gaston Paris. It is indeed Greek in its truth to nature, in the simplicity of its presentment, and in the perfection of its manner. There is no deep psychology in the characters, but then the people depicted are simple rustic folk, who wear their hearts on their sleeve, and whose inner lives and motives do not require, nay, would not bear, the dissecting-knife of a Bourget. *Calendau* (1867), the story of a princess held in bondage by a ruthless brigand, and eventually rescued by a youthful hero, is a comparative failure. There are many purple patches, but an epic must be judged as a whole, not piecemeal. The description of scenery is again masterly; but the old lore, which had charmed all readers in *Mirèio*, here becomes wearisome, its introduction being forced, not inevitable. The characters are mere symbols—indeed, the whole poem is obviously an allegory, the princess standing for Provence, the brigand for France, and the young lover for the Félibrige. Mistral lavished enormous labour on this work, which probably accounts for its lack of spontaneity, as also for the love he bears it ("Malgré la bienveillance de tous les journaux, le public en général se montra moins empressé pour *Calendau* que pour *Mireille*; non pas que le premier contienne moins de poésie, mais parce que dans *Mireille* la nature prédomine, et dans l'autre, à mon sens, c'est l'imagination. J'ai croyance pourtant que, si un jour ce pays n'est plus émasculé par une éducation fausse, beaucoup prendront plaisir à lire *Calendau*"). In 1876 (the same year in which he married Mlle Marie Rivière, of Dijon) was published the volume *Lis Isco d'Or*—a collection of the shorter poems Mistral had composed from the year 1848 onwards. Here he is again at his very best. Old legends, *strventes* (mostly, as in mediæval times, poems with a tendency), and lyrics—all are admirable. Even the *pièces d'occasion* may be reckoned with

the best of their kind. Two pieces, the *Coupe* and the *Princesse*, aroused violent controversy on their first appearance. They reproduce, in effect, the theme of *Calendau*, and Mistral was accused of trying to sow discord between the north and south of France. Needless to say, he was altogether innocent of such a design. His earnest desire to awaken in the Provençals a sense of their past achievement was not only compatible with a love of the whole of France, but inseparable from it. *Nerto* (1884) is a charming tale of Avignon in the olden days, in which a girl's purity triumphs over her lover's base designs and leads him to nobler thoughts. There is little individuality in the characters, which should rather be regarded as types; and we feel no terror or pity at the tragic close. But we are carried along by Mistral's art and by the brilliancy of his episodes; and though comparisons with Ariosto, that have so often been instituted, are altogether beside the mark, our poet has here achieved the object he had in view: he has told a pretty tale—it is almost a fairy tale—and he has imbued it with the proper touch of local colour and with the true spirit of romance. The play *La Rèino Jano* (1890) is a complete failure, if judged from the dramatic standpoint: it is rather a brilliant panorama, a series of stage pictures, and the characters neither live nor arouse our sympathy. In the great epic on the Rhone (*Lou Pouèmo dou Rouse*, 1897), the poet depicts the former barge-life of that river, and intertwines his narrative with the legends clustering round its banks, and with a graceful love episode. For the first time he employs blank verse, and uses it with great mastery; the lines roll on with a fine volume of sound. But his chief failing reappears in an accentuated form: the ancient lore is overdone, and produces a sense of weariness. A splendid piece of work is *Lou Tresor dou Féli-brige* (1886), which is fit to rank with Littré's great French dictionary. In these two volumes Mistral has deposited with loving care every word and phrase, every proverb, every scrap of legend that he had gathered during his many years' journeys in the south of France.

An excellent literary appreciation of the poet is that by GASTON PARIS, *Frédéric Mistral* (originally in the *Revue de Paris*, October and November 1894; then in *Penseurs et Poètes*, Paris, 1896). More elaborate accounts are WELTER, *Frédéric Mistral*, Marburg (1899); and DOWNER, *Frédéric Mistral*, New York, 1901 (with a full bibliography).

Mitcham (the Michelham, "great village," of Domesday Book), a suburb of London, in the Wimbledon parliamentary division of Surrey, 10 miles south of London Bridge by rail. Mitcham Common covers an area of 480 acres, and affords one of the best golf-courses near London. The neighbourhood abounds in market gardens and plantations of aromatic herbs for the manufacture of scents and essences. Population (1901), 14,904.

Mitchell, Donald Grant (1822—), American author, was born in Norwich, Connecticut, on the 12th of April, 1822. He graduated at Yale College in 1841; studied law, but soon took up literature as his profession. Throughout his life he showed a particular interest in agricultural and horticultural pursuits, which he followed at first in pursuit of health. He has produced books of travel; volumes of essays on rural themes, of which *My Farm of Edgewood* (1863) is the best; sketchy studies of English monarchs and of English and American literature; and a character-novel entitled *Doctor Johns* (1866), &c.; but is best known as the author, under the pseudonym of "Ik Marvel," of the gently sentimental essays contained in the volumes *Reveries of a Bachelor, or a Book of the Heart* (1850), and *Dream Life, a Fable of the Seasons* (1851), long popular in the United States, especially during the latter years of the

first literary period in that country, in which reminiscential egotism of the school of Irving had affected many writers and readers.

Mitchell, Silas Weir (1829—), American physician and author, was born in Philadelphia on the 15th of February 1829. He studied at the University of Pennsylvania in that city, and received the degree of M.D. at Jefferson Medical College in 1850. During the Civil War he had charge of the governmental wards for nervous injuries and maladies at Turner's Lane Hospital, Philadelphia, and at the close of the war became a specialist in nervous diseases, contributing numerous articles to medical and other scientific journals, and attaining a high place in his profession and in various academies and societies. While working in his chosen field as a physician, in 1863, he wrote a clever short story, combining physiological and psychological problems, entitled *The Case of George Dedlow*, which appeared in the *Atlantic Monthly*. Thenceforward Dr Mitchell, as a writer, divided his attention between professional and literary pursuits. In the former field he produced monographs on rattlesnake poison, on intellectual hygiene, on injuries to the nerves, on neurasthenia, on nervous diseases of women, on the effects of gunshot wounds upon the nervous system, and on the relations between nurse, physician, and patient; while on the latter he wrote juvenile stories, several volumes of respectable verse, and prose fiction of varying merit, which, however, gave him a leading place among the American authors of the close of the 19th century. His short stories, with the exception of the strong tale already named, are sketches rather than finished results; but his historical novels *Hugh Wynne, Free Quaker* (1897) and *The Adventures of François* (1898) take high rank amongst the best efforts in this branch of fiction.

Mitford, William (1744—1827), English historian, was the elder of the two sons of John Mitford, a barrister, who lived near Beaulieu, at the edge of the New Forest. Here, at Exbury House, his father's property, Mitford was born on the 10th of February 1744. He was educated at Cheam School, under the picturesque writer William Gilpin, but at the age of fifteen a severe illness led to his being removed, and after two years of idleness Mitford was sent, in July 1761, as a gentleman commoner to Queen's College, Oxford. In this year his father died, and left him the Exbury property and a considerable fortune. Mitford, therefore, being "very much his own master, was easily led to prefer amusement to study." He left Oxford (where the only sign of assiduity he had shown was to attend the lectures of Blackstone) without a degree, in 1763, and proceeded to the Middle Temple. But gradually he began to feel a curiosity "to become acquainted with the celebrated writings of the Greeks in their own language," and when he married Miss Fanny Molloy in 1766, and retired to Exbury for the rest of his life, he made the study of the Greek language and literature "without the assistance of any instructor" his constant hobby and occupation. After ten years passed in this way, his wife died, and in October 1776 Mitford went abroad. He was encouraged by French scholars whom he met in Paris, Avignon, and Nice to give himself systematically to the study of Greek history. But it was Gibbon, with whom he was closely associated when they both were officers in the South Hampshire Militia, who definitely suggested to Mitford the form which his work should take. In 1784 the first of the volumes of his *History of Greece* appeared, and the fifth and last of these quartos was published in 1810, after which the state of Mitford's eyesight and other physical infirmities, including

a loss of memory, forbade his continuation of the enterprise, although he painfully revised successive new editions. While his great book was slowly progressing, Mitford was engaged in a certain amount of public activity. He was a member of the House of Commons, with intervals, from 1785 to 1818, and he was for many years verderer of the New Forest and a county magistrate. It does not appear that at any time in his life William Mitford visited Greece. After a long and enfeebling illness he died at Exbury on his eighty-third birthday, 10th February 1827. In addition to his famous *History of Greece*, he published a few smaller works, most of them of a subsidiary character. Of these the most important was an *Essay on the Harmony of Language*, 1774. The style of Mitford is natural and lucid, but without any of the rich colour of Gibbon. He affected some oddities both of language and of orthography, for which he was censured and which he endeavoured to revise. But his political opinions, applied to the constitutions of the Greek republics, were still more severely treated, since Mitford was an impassioned anti-Jacobin, and thought that a king could do no wrong. His partiality for a monarchical form of government led him to be unjust to the Athenians. Hence his *History of Greece*, after having had no peer in European literature for half a century, faded in interest on the appearance of the more democratic work of Grote. Clinton, too, in his *Fasti Hellenici*, charged Mitford with "a general negligence of dates," though admitting that in his philosophical range "he is far superior to any former writer" on Greek history. Byron, who dilated on Mitford's shortcomings, nevertheless declared that he was "perhaps the best of all modern historians altogether." This Mitford certainly is not, but his pre-eminence in the little school of English historians who succeeded Hume and Gibbon it would be easier to maintain.

(E. G.)

Mithras.—The cult of Mithras is one of the most important Eastern cults which were introduced at Rome. The god was worshipped before the separation of the Iranian from the Indian Aryans. Among the early Persians he held a foremost place with Ahura-Mazda and Anahita. In the Avesta he has become less potent, and is one of the gods who serve Ahura-Mazda in his struggle against evil. He is the embodiment of created light, and is the god of truth. From Iran his worship spread to Babylonia, where it absorbed Chaldean elements. Old Persian gods became identified with the stars adored by the Babylonians, and were connected with the theory that the soul after death wanders through the region of the stars. From Babylon Mithras travelled to Pontus and Cappadocia, and while little known to the Greeks, was brought to Rome by soldiers and slaves. He is first mentioned by Statius in the *Thebais*, A.D. 90. The oldest known Roman Mithras inscriptions date from Trajan and Hadrian. First favoured by the lower classes, the cult spread upwards. Sculptures represent Mithras as (1) a boy with Phrygian cap, emerging from a rock and holding a torch, probably signifying Mithras as god of light, gilding the mountains; (2) shooting a rock whence comes a stream from which a man takes water: here he is the mythical bowman who causes rain to come upon the earth; (3) stabbing a bull: a serpent and a dog lick the blood, a scorpion grips the bull, a raven stands by, and boys hold torches: here the bull is the first creature made by Ahura-Mazda, the death of which is necessary for the creation of plants and animals; the scorpion is the animal of Añgra-Manyu (Ahriman), who tries to hinder the work of Ahura-Mazda; the serpent is the symbol of the earth enriched by the bull's blood; the dog catches the soul of the bull for new uses; the raven is probably

an emblem of the sun-god, signifying that the sacrifice is performed at his command.

The devotees of Mithras formed a community which consisted of seven divisions, *Coraces, Gryphi, Milites, Leones, Persae, Heliodromi, Patres*. At the head of the *Patres* was the *Pater Patrum*. The *Patres* do not seem to have been necessarily *sacerdotes*, a class which offered the sacrifices and was presided over by a *summus pontifex*. Worship was not conducted in temples. Each Mithraeum was a grotto, real or artificial. Existing examples are at Rome under the church of S. Clemente, and under the Capitol, and at Spoleto. That at Spoleto had three niches at the end for statues of Mithras and the two torch-bearers. Before them was a small altar inscribed "Soli invicto Mitrae Sacrum." Near it stood two large stones, one triangular and the other conical and perforated. The latter may have been an emblem of the rock from which Mithras was born. Some caves had two altars and a hole for the blood of the bull sacrificed. The Christians regarded Mithraism as a dangerous rival of Christianity. Its belief in a mediator, in the resurrection, the lustrations and the common meal of bread and water were points of contact. Apparently the Mithraists made the most of these resemblances, as is done in parts of India by Hindus who exalt Krishna against Christ. Investigation of early Christian worship has proved that it owes nothing to Mithraism. The only point still dubious is the origin of observing 25th December as Christmas. But the heathen Roman observance of 25th December seems to date from the Syrian sun worship introduced by Aurelian A.D. 270, while belief that Christ was born on 25th December can be traced back at Rome to Hippolytus c. 220. It is possible that 25th December was attained as the result of the strong belief that Christ died on 25th March. It was thought that He spent an exact number of years on earth, and thus 25th March was chosen for the Annunciation and 25th December reckoned from it.

For bibliography see article "Mithras" in W. H. Roscher's *Lexicon der Griechischen und Römischen Mythologie* (B.G. Teubner, Leipzig, 1894-97).

(L. P.)

Mitrovicza, a town of Hungary, in the county of Szerém, in the province of Croatia-Slavonia, on the Save, with 19,795 inhabitants in 1891, and 11,518 in 1901. It has an under *realschule*, many administrative and other offices, and a thriving trade. On its site once stood the Roman city of Syrmium, the capital of Pannonia, and later of Illyricum, where was born and buried the Emperor Probus, and where dwelt other Roman emperors. Its ancient buildings were destroyed by the Turks in 1396 and 1521.

Mittweida, a town of Germany, on the Zschopau, 12 miles by rail north of Chemnitz, in the circle of Leipzig, kingdom of Saxony. There are an engineering and electrotechnical institute, cotton and spinning mills, machinery, dye, earthenware, and furniture works. Population (1890), 11,298; (1900), 16,117.

Mivart, St George (1827-1900), English biologist, was born in London on 30th November 1827, and educated at Clapham Grammar School, Harrow and King's College, London, and afterwards at St Mary's, Oscott, since his conversion to Catholicism prevented him from going to Oxford. In 1851 he was called to the bar, but his interests were chiefly scientific, and he devoted himself to medical and biological studies. In 1862 he was appointed lecturer at St Mary's Hospital medical school, in 1869 he became a fellow of the Zoological Society, and in 1874 he was appointed professor of biology at University College, London. In 1873 he had published *Lessons in Elementary Anatomy*, and

a separate essay on *Man and Apes*. His monograph on APES written for the *Encyclopædia Britannica* was incorporated in the *Study of Mammals* by Flower and Lydekker, for which he also wrote *Skeleton and Reptiles*. In 1881 appeared *The Cat, an Introduction to the Study of Back-boned Animals*, in which the detailed study of one particular animal is made the starting-point of a general survey of its kindred. The careful and detailed work he bestowed on Insectivora and Carnivora has largely increased our knowledge of the anatomy of these groups. In 1871 his *Genesis of Species* had brought him into the controversy then raging round the question of evolution. While fully asserting evolution generally, Mivart denied its applicability to the human intellect. He represented the formation of new species as mainly due to one mode of action of that plastic innate power manifest on all hands in nature, as evidenced by many instances quoted by him. His views as to the relationship existing between human nature and intellect and animal nature in general were given in *Nature and Thought* (1882); and in the *Origin of Human Reason* (1899) he stated what he considered the fundamental difference between men and animals, pointing out where the human intellect differed from the highest psychical actions of brutes. In 1884, at the invitation of the Belgian episcopate, he became professor of the philosophy of natural history at Louvain. This university also conferred on him the degree of M.D. Some articles in the *Nineteenth Century*, in which Mivart advocated the claims of science even where they seemed to conflict with religion, were placed on the *Index Expurgatorius*, and a curious correspondence ensued between him and Cardinal Vaughan, in which Mivart vindicated his claim to hold liberal opinions while remaining in the Catholic Church; but the result was that, as he refused to recant, he was excommunicated. The episode was interesting as throwing light on the state of Roman Catholic sentiment in England; but Mivart died almost immediately afterwards (on 1st April 1900), and the discussion dropped.

(A. Z.)

Mława, a district town of Russian Poland, government of Płock, 7 miles from the Prussian frontier, and 78 miles by rail north-west of Warsaw, near the Prussian frontier. It has a *realschule*, agricultural machinery works, steam flour-mill, tanneries, and soap-works. It is an important railway junction, and has considerable trade in grain. Population (1897), 13,449.

Moberly, a city of Randolph county, Missouri, U.S.A., on the Missouri, Kansas and Texas and the Wabash railways, north of the centre of the state, at an altitude of 858 feet. It has a level prairie site and a regular plan, divided into four wards. It contains the machine shops of the Wabash railroad, in addition to varied manufactures. Population (1880), 6070; (1890), 8215; (1900), 8012, of whom 450 were foreign-born and 923 were negroes.

Mobile, a city and seaport of Alabama, U.S.A., capital of Mobile county, on the west side of the Mobile river near its mouth. Its site is level and its plan fairly regular; it has a good water-supply, and its business streets are paved with brick and wood. Four railways centre in the city, the Louisville and Nashville, the Mobile and Ohio, the Mobile, Jacksonville and Kansas City, and the Southern. Mobile is the only seaport of the state, and it has considerable export trade, consisting almost entirely of cotton. Its importance in this regard has, however, diminished greatly. In 1900 its manufacturing establishments had a total capital of \$3,294,238, and employed an average number of 2827 wage-earners.

The total products were valued at \$4,451,062, of which the most important were lumber and timber products (\$566,800) and flouring and grist-mill products (\$454,134). The city was rechartered in 1887, the state assuming most of the debt which had made it bankrupt. The assessed valuation of real and personal property in 1900, on a basis of about one-half of the full value, was \$15,986,201, the net debt was \$822,000, and the rate of taxation was \$26.50 per \$1000. Population (1890), 31,076; (1900), 38,469, of whom 2111 were foreign-born and 17,045 were negroes. The death-rate in 1900 was 25.9; the death-rate of the coloured population was about one-half greater than that of the white.

Models.—The term model denotes a tangible representation, whether the size be equal, or greater, or smaller, of an object which is either in actual existence, or has to be constructed in fact or in thought. More generally it denotes a thing, whether actually existing or only mentally conceived of, whose properties are to be copied. In foundries, the object of which a cast is to be taken, whether it be for engineering or artistic purposes, is usually first formed of some easily workable material, generally wood. The form of this model is then reproduced in clay or plaster, and into the mould thus obtained the molten metal is poured. The animate figures which serve the painter as types are described as models. The sculptor first makes a model of the object he wishes to chisel in some plastic material such as wax, ingenious and complicated contrivances being employed to transfer this wax model, true to nature, to the stone in which the final work is to be executed. In anatomy and physiology, models are specially employed as aids in teaching and study, and the method of *moulage* or chromoplastic yields excellent impressions of living organisms, and enables anatomical and medical preparations to be copied both in form and colour. A special method is also in use for making plastic models of microscopic and minute microscopic objects. That their internal nature and structure may be more readily studied, these are divided by numerous parallel transverse cuts, by means of a microtome, into exceedingly thin sections (see **MICROTOMY**). Each of these shavings is then modelled on an enlarged scale in wax or pulp plates, which are fixed together to form a reproduction of the object.

Models in the mathematical, physical, and mechanical sciences are of the greatest importance. Long ago philosophy perceived the essence of our process of thought to lie in the fact that we attach to the various real objects around us particular physical attributes—our concepts—and by means of these try to represent the objects to our minds. Such views were formerly regarded by mathematicians and physicists as nothing more than unfruitful speculations, but in more recent times they have been brought by Maxwell, Helmholtz, Mach, Hertz, and many others into intimate relation with the whole body of mathematical and physical theory. On this view our thoughts stand to things in the same relation as models to the objects they represent. The essence of the process is the attachment of one concept having a definite content to each thing, but without implying complete similarity between thing and thought; for naturally we can know but little of the resemblance of our thoughts to the things to which we attach them. What resemblance there is lies principally in the nature of the connexion, the correlation being analogous to that which obtains between thought and language, language and writing, the notes on the staff and musical sounds, &c. Here, of course, the symbolization of the thing is the important point, though, where feasible, the utmost possible correspondence is sought between the

Repre-
sentation
in thought.

two—the musical scale, for example, being imitated by placing the notes higher or lower. When, therefore, we endeavour to assist our conceptions of space by figures, by the methods of descriptive geometry, and by various thread and object models; our topography by plans, charts, and globes; and our mechanical and physical ideas by kinematic models—we are simply extending and continuing the principle by means of which we comprehend objects in thought and represent them in language or writing. In precisely the same way the microscope or telescope forms a continuation and multiplication of the lenses of the eye; and the notebook represents an external expansion of the same process which the memory brings about by purely internal means. There is also an obvious parallelism with representation by means of models when we express longitude, mileage, temperature, &c., by numbers, which should be looked upon as arithmetical analogies. Of a kindred character is the representation of distances by straight lines, of the course of events in time by curves, &c. Still, neither in this case nor in that of maps, charts, musical notes, figures, &c.; can we legitimately speak of models, for these always involve a concrete spatial analogy in three dimensions.

So long as the volume of matter to be dealt with in science was insignificant, the need for the employment of models was naturally less imperative; indeed, there are self-evident advantages in comprehending things without resort to complicated models, which are difficult to make, and cannot be altered and adapted to extremely varied conditions so readily as can the easily adjusted symbols of thought, conception, and calculation. Yet, as the facts of science increased in number, the greatest economy of effort had to be observed in comprehending them and in conveying them to others; and the firm establishment of ocular demonstration was inevitable in view of its enormous superiority over purely abstract symbolism for the rapid and complete exhibition of complicated relations. At the present time it is desirable, on the one hand, that the power of deducing results from purely abstract premisses, without recourse to the aid of tangible models, should be more and more perfected, and on the other that purely abstract conceptions should be helped by objective and comprehensive models in cases where the mass of matter cannot be adequately dealt with directly.

As regards their use, models may be divided into those which only subserve educational purposes and those which assist scientific investigation. In pure mathematics, especially geometry, models constructed of *papier-mâché* and plaster are chiefly employed to present to the senses the precise form of geometrical figures, surfaces, and curves. Surfaces of the second order, represented by equations of the second degree between the rectangular co-ordinates of a point, are very simple to classify, and accordingly all their possible forms can easily be shown by a few models, which, however, become somewhat more intricate when lines of curvature, loxodromics, and geodesic lines have to appear on their surfaces. On the other hand, the multiplicity of surfaces of the third order is enormous, and to convey their fundamental types it is necessary to employ numerous models of complicated, not to say hazardous, construction. In the case of more intricate surfaces it is sufficient to present those singularities which exhibit variation from the usual type of surface with synclastic or anticlastic curvatures, such as, for example, a sharp edge or point, or an intersection of the surface with itself; the elucidation of such singularities is of fundamental importance in modern mathematics.

In physical science, again, models that are of unchangeable form are largely employed. For example, the opera-

tion of the refraction of light in crystals can be pictured if we imagine a point in the centre of the crystal whence light is dispersed in all directions. The aggregate of the places at which the light arrives at any instant after it has started is called the wave-front. This surface consists of two cups or sheets fitting closely and exactly one inside the other. The two rays into which a single ray is broken are always determined by the points of contact of certain tangent planes drawn to those sheets. With crystals possessing two axes these wave-surfaces display peculiar singularities in the above sense of the term, in that the inner sheet has four protuberances, while the outer has four funnel-like depressions, the lowest point of each depression meeting the highest point of each protuberance. At each of these funnels there is a tangent-plane that touches, not in a single point, but in a circle bounding the depression, so that the corresponding ray of light is refracted, not into two rays, but into a whole cone of light—the so-called conical refraction theoretically predicted by Hamilton and experimentally detected by Lloyd. These conditions, which it is difficult adequately to express in language, are self-evident so soon as the wave-surface formed in plaster lies before our eyes. In thermodynamics, again, similar models serve, among other purposes, for the representation of the surfaces which exhibits the relation between the three thermodynamic variables of a body, *e.g.*, between its temperature, pressure, and volume. A glance at the model of such a thermodynamic surface enables the behaviour of a particular substance under the most varied conditions to be immediately realized. When the ordinate intersects the surface but once a single phase only of the body is conceivable, but where there is a multiple intersection various phases are possible, which may be liquid or gaseous. On the boundaries between these regions lie the critical phases, where transition occurs from one type of phase into the other. If for one of the elements a quantity which occurs in calorimetry be chosen—for example, entropy—information is also gained about the behaviour of the body when heat is taken in or abstracted.

After the stationary models hitherto considered come the manifold forms of moving models, such as are used in geometry, to show the origin of geometrical figures from the motion of others; *e.g.*, the origin of surfaces from the motion of lines. These include the thread models, in which threads are drawn tightly between movable bars, cords, wheels, rollers, &c. In mechanics and engineering an endless variety of working models are employed to convey to the eye the working either of machines as a whole, or of their component and subordinate parts. In theoretical mechanics models are often used to exhibit the physical laws of motion in interesting or special cases; *e.g.*, the motion of a falling body or of a spinning-top, the movement of a pendulum on the rotating earth, the vortical motions of fluids, &c. Akin to these are the models which execute more or less exactly the hypothetical motions by which it is sought to explain various physical phenomena, as for instance the complicated wave-machines which present the motion of the particles in waves of sound (now ascertained with fair accuracy), or the more hypothetical motion of the atoms of the ether in waves of light.

The varying importance which in recent times has been attached to models of this kind is intimately connected with the changes which have taken place in our conceptions of Nature. The first method by which an attempt was made to solve the problem of the universe was entirely under the influence of Newton's laws. In analogy to his laws of celestial gravitation, all bodies were conceived of as consisting of points of matter—atoms or molecules—to which was attributed a direct action at a distance. The circumstances of this action at

Theories of Nature.

a distance, however, were conceived as differing from those of the Newtonian law of attraction, in that they could explain the properties not only of solid elastic bodies, but also those of fluids, both liquids and gases. The phenomena of heat were explained by the motion of minute particles absolutely invisible to the eye, while to explain those of light it was assumed that an impalpable medium, called luminiferous ether, permeated the whole universe; to this were attributed the same properties as were possessed by solid bodies, and it was also supposed to consist of atoms, although of a much finer composition. To explain electric and magnetic phenomena the assumption was made of a third species of matter—electric fluids which were conceived of as being more of the nature of fluids, but still consisting of infinitesimal particles, also acting directly upon one another at a distance. This first phase of theoretical physics may be called the direct one, in that it took as its principal object the investigation of the internal structure of matter as it actually exists. It is also known as the mechanical theory of nature, in that it seeks to trace back all natural phenomena to motions of infinitesimal particles, *i.e.*, to purely mechanical phenomena. In explaining magnetic and electrical phenomena it inevitably fell into somewhat artificial and improbable hypotheses, and this induced Maxwell, adopting the ideas of Faraday, to propound a theory of electric and magnetic phenomena which was not only new in substance, but also essentially different in form. If the molecules and atoms of the old theory were not to be conceived of as exact mathematical points in the abstract sense, then their true nature and form must be regarded as absolutely unknown, and their groupings and motions, required by theory, looked upon as simply a process having more or less resemblance to the workings of Nature, and representing more or less exactly certain aspects incidental to them. With this in mind, Maxwell propounded certain physical theories which were purely mechanical so far as they proceeded from a conception of purely mechanical processes. But he explicitly stated that he did not believe in the existence in Nature of mechanical agents so constituted, and that he regarded them merely as means by which phenomena could be reproduced, bearing a certain similarity to those actually existing, and which also served to include larger groups of phenomena in a uniform manner and to determine the relations that held in their case. The question no longer being one of ascertaining the actual internal structure of matter, many mechanical analogies or dynamical illustrations became available, possessing different advantages; and as a matter of fact Maxwell at first employed special and intricate mechanical arrangements, though later these became more general and indefinite. This theory, which is called that of mechanical analogies, leads to the construction of numerous mechanical models. Maxwell himself and his followers devised many kinematic models, designed to afford a representation of the mechanical construction of the ether as a whole as well as of the separate mechanisms at work in it; these resemble the old wave-machines, so far as they represent the movements of a purely hypothetical mechanism. But while it was formerly believed that it was allowable to assume with a great show of probability the actual existence of such mechanisms in Nature, yet nowadays philosophers postulate no more than a partial resemblance between the phenomena visible in such mechanisms and those which appear in Nature. Here again it is perfectly clear that these models of wood, metal, and cardboard are really a continuation and integration of our process of thought; for, according to the view in question, physical theory is merely a mental construction of mechanical models, the working of which

we make plain to ourselves by the analogy of mechanisms we hold in our hands, and which have so much in common with natural phenomena as to help our comprehension of the latter.

Although Maxwell gave up the idea of making a precise investigation into the final structure of matter as it actually is, yet in Germany his work, under Kirchhoff's lead, was carried still farther. Kirchhoff defined his own aim as being to describe, not to explain, the world of phenomena; but as he leaves the means of description open his theory differs little from Maxwell's, so soon as recourse is had to description by means of mechanical models and analogies. Now the resources of pure mathematics being particularly suited for the exact description of relations of quantity, Kirchhoff's school laid great stress on description by mathematical expressions and formulæ, and the aim of physical theory came to be regarded as mainly the construction of formulæ by which phenomena in the various branches of physics should be determined with the greatest approximation to the reality. This view of the nature of physical theory is known as mathematical phenomenology; it is a presentation of phenomena by analogies, though only by such as may be called mathematical.

Another phenomenology in the widest sense of the term, maintained especially by Mach, gives less prominence to mathematics, but considers the view that the phenomena of motion are essentially more fundamental than all the others to have been too hastily taken. It rather emphasizes the prime importance of description in the most general terms of the various spheres of phenomena, and holds that in each sphere its own fundamental law and the notions derived from this must be employed. Analogies and elucidations of one sphere by another, *e.g.*, heat, electricity, &c., by mechanical conceptions, this theory regards as mere ephemeral aids to perception, which are necessitated by historical development, but which in course of time either give place to others or entirely vanish from the domain of science.

All these theories are opposed by one, called in Germany Energetics (in the narrower sense), which looks upon the conception of energy, not that of matter, as the fundamental notion of all scientific investigation. It is in the main based on the similarities energy displays in its various spheres of action, but at the same time it takes its stand upon an interpretation or explanation of natural phenomena by analogies which, however, are not mechanical, but deal with the behaviour of energy in its various modes of manifestation.

A distinction must be observed between the models which have been described and those experimental models which present on a small scale a machine that is subsequently to be completed on a larger, so as to afford a trial of its capabilities. Here it must be noted that a mere alteration in dimensions is often sufficient to cause a material alteration in the action, since the various capabilities depend in various ways on the linear dimensions. Thus the weight varies as the cube of the linear dimensions, the surface of any single part and the phenomena that depend on such surfaces are proportionate to the square, while other effects, such as friction, expansion, and conduction of heat, &c., vary according to other laws. Hence a flying machine, which when made on a small scale is able to support its own weight, loses its power when its dimensions are increased. The theory, initiated by Newton, of the dependence of various effects on the linear dimensions, is treated at length in the text-books of mechanics. Under simple conditions it may often be affirmed that in comparison with a large machine a small one has the same

**Experi-
mental
models.**

capacity, with reference to a standard of time which must be diminished in a certain ratio.

Of course experimental models are not only those in which purely mechanical forces are employed, but also include models of thermal, electro-magnetic, and other engines; *e.g.*, dynamos and telegraphic machines. The largest collection of such models is to be found in the museum of the New York Patent Office, in which a model of every patented invention must be deposited. Sometimes, again, other than purely mechanical forces are at work in models for purposes of investigation and instruction. It often happens that a series of natural processes, such as motion in liquids, internal friction of gases, and the conduction of heat and electricity in metals, may be expressed by the same differential equations; and it is frequently possible to follow by means of measurements one of the processes in question —*e.g.*, the conduction of electricity just mentioned. If then there be shown in a model a particular case of electrical conduction in which the same conditions at the boundary hold as in a problem of the internal friction of gases, we are able by measuring the electrical conduction in the model to determine at once the numerical data which obtain for the analogous case of internal friction, and which could only be ascertained otherwise by intricate calculations. Intricate calculations, moreover, can very often be dispensed with by the aid of mechanical devices, such as the ingenious calculating machines which perform additions and subtractions and very elaborate multiplications and divisions with surprising speed and accuracy, or apparatus for solving the higher equations, for determining the volume or area of geometrical figures, for carrying out integrations, and for developing a function in a Fourier's series by mechanical means. (L. Bo.)

Modena, a town, archiepiscopal see, and capital of the province of Modena, Emilia, Italy, 23 miles north-west of Bologna by rail. The ducal palace now shelters the military school and the astronomical observatory, while the art galleries and the libraries are housed in the Albergo Arti, built by Duke Francesco III. in 1764. In 1898 the university was attended by 435 students, with 45 professors. Amongst the public statues is a particularly fine one of Victor Emmanuel (1890), by Gibellini; others are of the poet Tassoni (1860), Menotti (1879), and Muratori (1853). There is a noteworthy town hall, with arcades, dating from 1194, but in part rebuilt in 1826. Population (1881), 31,053; of commune (1901), 64,941.

Modica, a town of the province of Syracuse, Sicily, Italy, 63 miles south-west of Syracuse by rail. It has a technical school and an industrial institute; also factories for macaroni, sweetmeats made from oranges, lemons, &c., olive oil presses, limestone quarries, and cheese factories. Population (1881), 38,390; (1899), about 42,000.

Modjeska, Helena (1844—), Polish actress, was born at Cracow, 12th October 1844. Her father, Michael Opido, was something of a musician, and her tastes soon declared themselves strongly in favour of a dramatic career; but it was not until after her marriage in 1861 that she first attempted to act, and then it was with a company of strolling players. Her husband (whose name, Modrzejewski, she afterwards adopted in a simplified form for stage purposes) died in 1865. Three years later she married Count Bozenta Chlapowski, a Polish politician and critic, and almost immediately after that event received an invitation to act at Warsaw. There she remained for seven or eight years, and won a high position in her art. In 1876 she went with her

husband to California, where they settled on a ranch. This new career, however, proved a failure, and Madame Modjeska returned to the stage. She appeared in San Francisco in 1877, in an English version of *Adrienne Lecouvreur*, and, in spite of her imperfect command of the language, achieved a remarkable success. She continued to act principally in America, but was also seen from time to time in London and other towns in the United Kingdom, her repertory including several Shakespearean rôles and a variety of emotional parts in modern drama.

Mödling, an old town in the government district of the same name in Lower Austria, about 10 miles south of Vienna, at the entrance of the Brühl valley. It has iron and sulphur baths, and is a popular local summer resort, being connected with Vienna by rail and tramway. There is a park, a "cur-salon," and an open-air theatre; and it possesses a Gothic church, with a crypt dating from the 15th century, and a still older Romanesque burial chapel. It has a considerable iron and metal industry, including railway material, and manufactures shoes, varnish, &c. Population (1890), 11,120; (1900), 15,304, mostly German and Catholic.

Moe, Jørgen Engebretsen. See ASBJØRNSSEN.

Moffat, a burgh of barony, police burgh, and health resort of Upper Annandale, Dumfriesshire, Scotland, 52 miles south-south-west of Edinburgh by road. Its spa was purchased by the Burgh Commissioners from a company in 1898. There are a hydropathic establishment and an endowed workmen's institute, containing a library and baths. Episcopal, Established, and United Free churches have been erected. The academy is a secondary school, and the town contains several well-known private boarding schools. Population (1891), 2291; (1901), 2153.

Mogador (*Es-Sheira*), seaport on the west coast of Morocco, Africa, 128 miles west by south of Morocco. It is the best-built port of the sultanate, and second in point of trade. Although formerly much more important, it still includes the largest variety of exports. The climate, although damp, is healthy, and is strongly recommended for chest complaints. The rainfall varies between 13 and 20 inches annually. Exports: 1896, £225,963; 1900, £407,592, the principal items being almonds (51 per cent.), goat-skins, olive oil, beeswax, gums, and eggs. Imports: 1896, £225,430; 1900, £246,231. In the same year the port was entered and cleared by 143 vessels of 132,326 tons, an increase of 6538 tons since 1896. Population, about 20,000.

Moghilev, a government of western Russia, having Minsk on the W., Smolensk on the N.E., and Chernigov on the E. and S. Its area occupies 18,551 square miles. It is built up of Devonian deposits in the north, of Cretaceous in the east, and of Tertiary elsewhere, but generally is covered with a thick layer of Glacial and later alluvial deposits. Interesting finds from the Stone Age, as well as remains of the mammoth, have been made. The population in 1898 was 1,717,291, of whom 861,533 were women, and 146,752 lived in towns (census of 1897). Both birth-rate (77,790 in 1897) and death-rate (47,158) are high. The population is mostly White Russian, and was distributed as follows according to religion: Greek Orthodox, 1,426,347; Raskolniks, 26,286; Roman Catholics, 50,344; Protestants, 5651; Jews, 208,560; Mussulmans, 103.

In 1899, out of a total of 11,309,200 acres, 4,622,000 acres were held in communal ownership by the peasants, 5,776,300 acres were owned by landlords owning more than 270 acres each, and 399,000 acres by small owners. Most of the private owners belong to the nobility. At the same time 3,185,600 acres were under crops, and the produce

of the crops in 1899 was: wheat, 219,000 cwt.; rye, 5,353,700; oats, 2,893,600; of all cereals, 10,200,000 cwt. Flax, hemp, and tobacco are also grown. In 1897 there were 401,960 horses, 470,770 horned cattle, 427,000 sheep, and 439,150 swine. In the same year 820 factories employed 6835 hands, but showed an aggregate return of only £528,400. Paper, spirits, wire and nails, leather, and tiles were the chief products. Nearly 60,000 children were in receipt of education. The province is divided into 11 districts, of which the chief towns, with their population in 1897, were: Moghilev-on-Dnieper, or Moghilev Gubernskiy (43,106 in 1897), Chausy (5550), Cherikoff (5250), Gubel (35,846), Gorki (6730), Klinovichi (4706), Mstislavl (8467), Orsha (13,161), Rogacheff (9103), Staryi Bykhov (6354), and Syenno (4061). Shklov, another town, has 10,630 inhabitants. (P. A. K.)

Moguer, a town of Spain, in the province of Huelva, on the Rio Tinto, not far from the sea. The population, 8750 in 1887, was only 7689 in 1897. The streets are regular, and contain many modern houses. There are distilleries and flour mills, and vessels of light draught can come up to the town. There is an active export of wine and oil.

Mohl, Hugo von (1805–1872), German botanist, was born at Stuttgart on 8th April 1805. He came of a family connected on both sides with the higher class of state officials of Würtemberg, and he and his three brothers justified by their distinguished careers their excellent early education at home. While a pupil at the gymnasium he pursued botany and mineralogy in his leisure time, till in 1823 he entered the University of Tübingen. After graduating with distinction in medicine he went to Munich, where he met a distinguished circle of botanists, and found ample material for research. This seems to have determined his career as a botanist, and he started in 1828 those anatomical investigations which he continued till his death. In 1832 he was appointed professor of botany in Tübingen, a post which he never left. Unmarried, his pleasures were in his laboratory and library, and in perfecting optical apparatus and microscopic preparations, for which he showed extraordinary manual skill. He was largely a self-taught botanist from boyhood, and, little influenced in his opinions even by his teachers, preserved always his independence of view on scientific questions. He received many honours during his lifetime, and was elected Foreign Fellow of the Royal Society in 1868. Von Mohl's writings cover a period of forty-four years; the most notable of them were republished in 1845 in a volume entitled *Vermischte Schriften*. (For lists of his works see *Botanische Zeitung*, 1872, p. 576, and *Royal Soc. Catalogue*, 1870, vol. iv.) They dealt with a variety of subjects, but chiefly with the structure of the higher forms, including both rough anatomy and minute histology. The word "protoplasm" was his suggestion; the nucleus had already been recognized by Brown and others, but von Mohl showed in 1844 that the protoplasm is the source of those movements which at that time excited so much attention. He recognized under the name of "primordial utricle" the protoplasmic lining of the vacuolated cell, and first described the behaviour of the protoplasm in cell-division. These and other observations led to the overthrow of Schleiden's theory of origin of cells by free-cell-formation. His contributions to knowledge of the cell-wall were no less remarkable; he held the view now generally adopted of growth of cell-wall by apposition. He first explained the true nature of pits, and showed the cellular origin of vessels and of fibrous cells; he was, in fact, the true founder of the cell theory. Clearly the author of such researches was the man to collect into one volume the theory of cell-formation—this he did in his treatise *Die Vegetabilische Zelle* (1851), a short work translated into English (Ray Society, 1852). Von Mohl's early investigations on the structure of palms, of cycads, and of tree-ferns permanently laid the foundation of all

later knowledge of this subject; so also his work on *Isoetes* (1840). His later anatomical work was chiefly on the stems of dicotyledons and gymnosperms; in his observations on cork and bark he first explained the formation, and the origin of different types of bark, and corrected errors relating to lenticels. Following on his early demonstration of the origin of stomata (1838), he wrote a classical paper on their opening and closing (1850). In 1843 he started in conjunction with Schlechtendal the weekly *Botanische Zeitung*, which he jointly edited till his death. He was never a great writer of comprehensive works; no text-book exists in his name, and it would indeed appear from his withdrawal from co-operation in Hofmeister's *Handbuch* that he had a distaste for such efforts. In his latter years his productive activity fell off, doubtless through failing health, and he died suddenly at Tübingen on 1st April 1872.

See SACHS, *History of Botany*, p. 292, &c.—DE BARY, *Botanische Zeitung*, 1872, p. 561.—*Roy. Soc. Proc.* vol. xxiii. p. 1.—*Allgemeine Deutsche Biographie*, vol. xxii. p. 55. (F. O. B.)

Mohmand Campaign, The.—The year 1897 witnessed an almost general outbreak among the tribes on the north-west frontier of India. The tribes involved were practically independent, but the new frontier arranged with the Amir of Afghanistan, and demarcated by Sir Mortimer Durand's commission of 1893–94, brought them within the British sphere of influence. The great dread of these high-spirited mountaineers was annexation, and the hostility shown during the demarcation led to the Waziri expedition of 1894. Other causes, however, contributed to bring about the outbreak of 1897. The easy victory of the Turks over the Greeks gave rise to excitement throughout the Mahomedan world, and the publication by the Amir of Afghanistan, in his assumed capacity of king of Islam, of a religious work, in portions of which fanatical antipathy to Christians was thinly veiled, aroused a warlike spirit among the border Mahomedans. The growing unrest was not recognized, and all appeared quiet, when, on 10th June 1897, a detachment of Indian troops escorting a British frontier officer was suddenly attacked during the mid-day halt in the Tochi valley, where, since the Waziri expedition of 1894–95, certain armed posts had been retained by the Government of India. On the 29th July, with equal suddenness, the fortified posts at Chakdara and Malakand, in the Swat valley, which had been held since the Chitral expedition of 1895, were for several days fiercely assailed by the usually peaceful Swatis under the leadership of the Mad Mullah. On 8th August the village of Shankaghar, within a few miles of Peshawur, and in British territory, was raided by the Mohmands, while the Afridis besieged the fortified posts on the Samana ridge, which had been maintained since the expeditions of 1888 and 1891. Finally, the Afridis, within a few days, captured all the British posts in the Khyber Pass. A division commanded by Major-General Sir Bindon Blood was assembled at Nowshera. The post at Malakand was reached on 1st August, and on the following day Chakdara was relieved. The punishment of the Afridis was deferred till the preparations for the Tirah campaign (see TIRAH) could be completed. The Mohmands, however, could be immediately dealt with, and against them the two brigades of Sir Bindon Blood's division advanced from Malakand simultaneously with the movement of another division under Major-General (afterwards Sir Edmund) R. Elles from Peshawur; it was intended that the two columns should effect a junction in Bajaor. About the 6th September the two forces advanced, and Major-General Blood reached Nawagai on 14th September, having detached a brigade to cross the Rambat Pass. This brigade being sharply attacked in camp at Markhanai at the foot of the pass

on the night of the 14th, was ordered to turn northwards and punish the tribesmen of the Mamund valley. On the 15th Brigadier- (afterwards Major-) General Jeffreys camped at Inayat Killa, and on the following day he moved up the Mamund valley in three columns, which met with strong resistance. A retirement was ordered, the tribesmen following, and when darkness fell the general, with a battery and a small escort, was cut off, and with difficulty defended some buildings until relieved. The casualties in this action numbered 149. This partial reverse placed Major-General Blood in a position of some difficulty. He determined, however, to remain at Nawagai, awaiting the arrival of Major-General Elles, and sent orders to Brigadier-General Jeffreys to prosecute the operations in the Mamund valley. From the 18th to the 23rd these operations were carried on successfully, several villages being burned, and the Mamunds were disheartened. Meanwhile, the camp at Nawagai was heavily attacked on the night of the 20th by about 4000 men belonging to the Hadda Mullah's following. The attack was repulsed with loss, and on the 21st Generals Blood and Elles met at Lakarai. The junction having been effected, the latter, in accordance with the scheme, advanced to deal with the Upper Mohmands in the Jarobi and Koda Khel valleys, and they were soon brought to reason by his successful and well-conducted operations. The work of the Peshawur division was now accomplished, and it returned to take part in the Tirah campaign. Its total casualties were about 30 killed and wounded. On the 22nd Major-General Blood joined Brigadier-General Jeffreys, and on the 24th he started with his staff for Panjkora. On the 27th Brigadier-General Jeffreys resumed punitive operations in the Mohmand valley, destroying numerous villages. On the 30th he encountered strong opposition at Agrah, and had 61 casualties. On 2nd October Sir Bindon Blood arrived at Inayat Killa with reinforcements, and on the 11th the Mohmands tendered their submission. The total British loss in the Mohmand valley was 282 out of a force which never exceeded 1200 men. After marching into Bunar, and revisiting the scenes of the Ambeyla expedition of 1863, the Malakand field-force was broken up on 21st January. The objects of the Mohmand expedition were completely attained, in spite of the great natural difficulties of the country. The employment of imperial service troops with the Peshawur column marked a new departure in frontier campaigns.

(C. J. B.)

Moji, a Japanese town on the Kiushiu side of the Shimonoseki strait. The strait being only one mile in width, Moji and Shimonoseki would be practically the same port did not the swiftness of the current along the latter shore make it convenient for vessels to anchor on the Moji side. Moji is one of the places voluntarily opened by the Japanese for purposes of direct export. It is the starting point of the Kiushiu railway, and as there is abundance of coal in its neighbourhood, it promises to become a town of great importance. In 1890 it was little more than a hamlet, but it had in 1901 a population of 25,274, and its foreign trade aggregates nearly £700,000.

Mokha. See ARABIA.

Mola di Bari, a seaport town of the province of Bari, Apulia, Italy, on the Adriatic coast, 12 miles east-south-east of Bari by the railway to Brindisi. Population (1881), 12,070; (1899), 13,000.

Mold, contributory parliamentary borough, market town, and railway station of Flintshire, Wales, 11 miles west by south of Chester. There are extensive collieries,

potteries, limestone quarries, and lead mines in the neighbourhood. Population (1891), 4457; (1901), 4263.

Molenbeek-Saint-Jean, a town of Belgium, in the province of Brabant, north-west of Brussels, one of the eight communes constituting the capital, with a station on the suburban railway running round the city. It has been called the Manchester of Belgium, on account of its great manufacturing establishments. The population (communal) (1880), 41,737; (1900), 58,445.

Molesworth, Mary Louisa (1839—), Scottish writer, daughter of Major-General Stewart, of Strath, N.B., was born in Rotterdam, 29th May 1839, and was educated partly in Great Britain and partly abroad. In 1861 Miss Stewart married Major R. Molesworth. She began writing stories while quite young, and her first novels (*Lover and Husband*, 1869, to *Cicely*, 1874) appeared under the pseudonym of "Ennis Graham." Mrs Molesworth is best known, however, as a writer of books for the young. Her *Tell Me a Story* (1875), *Carrots* (1876), and *The Cuckoo Clock* (1877) at once established her reputation in that line, and were succeeded by many others.

Molfetta, a seaport town and episcopal see of the province of Bari, Apulia, Italy, on the Adriatic coast, 16 miles north-west of Bari by rail. It has manufactures of macaroni and olive oil, shipbuilding, brickworks, fishing, and an active coasting trade, the port being cleared by approximately 250,000 tons annually. Population (1881), 29,697; (1899), about 30,000.

Moline, a city of Rock Island county, Illinois, U.S.A., on the east bank of the Mississippi river, adjoining Rock Island, and opposite the upper end of the island, in the north-western part of the state, at an altitude of 574 feet. It has four railways, the Chicago, Burlington and Quincy, the Chicago, Milwaukee and St Paul, the Chicago, Rock Island and Pacific, and the Davenport, Rock Island and North-western. In 1900 the city contained 157 manufacturing establishments, with a total capital of \$11,165,701, an average number of 4438 wage-earners, and products valued at \$10,000,282. Moline is noted for its manufacture of agricultural implements, and especially for its farm waggons. Population (1890), 12,000; (1900), 17,248, of whom 5699 were foreign-born and 268 were negroes.

Molique, Wilhelm Bernhardt (1802-1869), German violinist and composer, was born at Nuremberg, 7th October 1802, and learnt the violin at Munich under Pietro Rovelli. In 1826 he became music-director at Stuttgart. As a composer for the violin Molique was commonly compared with Spohr. Some of his songs, too, were charming, and have survived. He died at Cannstadt in 1869.

Mollusca.—Until comparatively recently, the number of types of Mollusca which had been studied from the morphological standpoint was relatively inconsiderable. The different subdivisions of the group thus seemed quite distinct and easily characterized; and the really intimate relations between them were not apparent. The first, but fruitless, attempt at a phylogeny of Mollusca was made by von Jhering (1) in 1877—that is to say, at a time when our knowledge of the organization and development of these organisms was still inadequate. But, a decade later, numerous studies were begun with the aim of investigating the more primitive forms in each group, and thus of throwing light on morphology by means of phylogeny. The article by Ray Lankester in an earlier volume of this work (ninth ed., vol. xvi.) contributed not a little to the genesis of this movement; hence the

fact that since its publication our knowledge of Molluscs has made such great strides, the cause being, not so much the large number of memoirs as the phylogenetic tendency of many of them. (See list at the end of this article.)

Classification.—It has not been necessary to alter the boundaries of the group, but the genus *Rhodope* has been definitely removed as a Platyhelminth (Böhmig, 14). The affinity of the Aplacophora and Chitonidæ to one another has been completely confirmed, and the molluscan nature of these two subdivisions is now hardly questioned. The only three modifications in the general classification which have been introduced since the ninth edition of this Encyclopædia are as follows:—(a) the class Cephalopoda contains only the Siphonopoda of Lankester, the Pteropoda being excluded; (b) the class Gastropoda comprises only the Anisopleura of Lankester plus the Pteropoda (Boas, 4, and Pelseener, 5), a more complete knowledge of the Aplacophora and Polyplacophora having shown that the Isopleura of Lankester form a distinct class = the Amphineura of von Jhering; (c) on the other hand the class Lamellibranchia no longer constitutes a distinct "branch," in contrast to the remaining Mollusca; as a result of the work of Pelseener (6), it is recognized as having great special affinity to the Gastropoda and Scaphopoda, these three groups being capable of union into one branch, the Prohipidoglossomorpha (Grobben); the name being taken from their common ancestor Prohipidoglossum (Pelseener). The following table summarizes the division into classes which is generally adopted at the present day:—

PHYLUM MOLLUSCA.

Class	I. Amphineura	} Branch
"	II. Gastropoda	
"	III. Scaphopoda	
"	IV. Lamellibranchia	
"	V. Cephalopoda	
		Prohipidoglossomorpha

Morphology.—The general morphological characters are obviously those of the more primitive forms of the different classes, for in each class the same specializations may be observed—the loss of shell, foot, ctenidia, and radula. This is the case not only in Lamellibranchia, but also in numerous Gastropoda (Eulimidæ, Pyramidellidæ, Coralliophilidæ, Phyllidiidæ, Thetylidæ, &c.), in several Aplacophora, and even in Cephalopoda (Cirroteuthidæ). The nervous system consists of two pedal cords and two pallial cords, united by a supra-oesophageal (cerebral) commissure which innervates the principal sense-organs, and also by an infracæsophageal (labial) commissure, from which arise the stomato-gastric nerves. The alimentary canal exhibits a radula-sac on its anterior portion. The circulatory system is closed, allowing no water to enter the blood; respiration is effected by a pair of ctenidia. The coelom is represented only by the gonad and the pericardium; and is not an enterocœl, for its wall is derived from endodermal elements in the neighbourhood of the blastopore; these sink down between the adjacent cells, or divide, giving rise to other elements which interpose themselves between ectoderm and endoderm. The dorsal invagination for the shell-gland, often present as early as a gastrula-stage, is notable as forming the mantle and secreting the embryonic shell. The *Schematic Mollusc* (the *Archimollusc* of Lankester) is a generalized hypothetical type which summarizes the principal features which we believe to have been possessed by those ancestral organisms from which have descended all the classes of Molluscs existing at the present day. In addition to many of the general morphological characters just enumerated, it may be conceived to have possessed a symmetrical organization, with the anal orifice at the posterior extremity, and on the dorsal surface a shell which was not covered by mantle-folds.

The two portions of the primitive coelom were continuous, namely, the anterior or gonadial and the posterior or pericardial; each of these possessed its pair of nephridia (retained in some Cephalopoda and Polyplacophora), an anterior or genital pair, a posterior or renal pair.

Class I. **Amphineura** (= *Isopleura*).—Without torsion, possessing an elongate body, a heart, posterior anal and renal openings, and spicules in the integument; no visceral commissure.

Subclass A. **POLYPLACOPHORA**.—Mantle with a shell of eight articulated valves; foot for crawling; ctenidia metamericly segmented; one pair of genital nephridia. Families: Lepidopleuridæ, Ischnochitonidæ, Acanthochitonidæ, Cryptoplacidæ, Chitonidæ.

Subclass B. **APLACOPHORA**.—Foot vestigial; mantle occupying the whole surface of the body, and devoid of shell; gonads opening into the pericardium.

Order 1. *Neomenioidæ*.—A longitudinal ventral groove; the foot represented by a ciliated ridge; gonads paired, hermaphrodite. About forty species, distributed not only in the northern hemisphere, but also in the Malayan, Australian, and Antarctic regions. Principal genera: *Neomenia*, Tullberg; *Paramenia*, Pruv.; *Proneomenia*, Hubr.; *Ismenia*, Pruv.; *Lepidomenia*, Kowal. Mar.; *Dondersia*, Hubr.

Order 2. *Chaetodermoidæ*.—No pedal ridge; two ctenidia, posterior, symmetrical, and bipectinate; sexes separate. Genus: *Chaetoderma*, Loven.

The shell of the Polyplacophora is formed of two layers—the one deep and compact (articulamentum); the other (tegumentum) is alone to be seen externally, and is pierced by numerous vertical canals

FIG. 1.—Pallial Eye and Aesthetes of *Acanthopleura spiniger* (Moseley).

through which pass sense-organs. The tegumentum is a secondary structure, derived from the edges of the mantle which overlap the border of the articulamentum. The pallial sense-organs which perforate the tegumentum are epithelial papillæ, innervated by the pallial cords, containing nerve-anal bulbs, and covered by a dome of cuticle; they are termed, according to size, micræsthetes and megæsthetes. In some cases (*Tonicia*, *Chaetopleura*) megæsthetes are modified into eyes, formed by a deep retina, a lens, a calcareous cornea, and an envelope of pigment (15). The ctenidia of the Polyplacophora are metamericly segmented, and form from four to eighty pairs. They are arranged on both sides of the body in rows between mantle and foot, as holobranchs or merobranchs. The largest pair of branchiæ is placed immediately behind the renal openings, and corresponds to the two ctenidia of other Molluscs, the original ctenidia being repeated anteriorly and posteriorly in the Mesomacrobanchs, anteriorly only in the Metamacrobanchs. In adults of various species, the number of branchiæ is greater than in young specimens; and there is often a numerical asymmetry on the two sides.

In all Amphineura (including *Neomeniidæ*) there is a true heart with a contractile ventricle formed of the hinder part of the dorsal vessel. The ventricle in Polyplacophora has two lateral auricles, continuous posteriorly, with which it communicates by one or more openings, which occasionally are asymmetrical. The extension anteriorly of the nephridia is generally proportionate to that of the rows of branchiæ. The external opening is placed immediately in front of the largest branchia. The gonad is paired in *Nuttallochiton* and the *Neomeniidæ*; in other cases it is single.

It always occupies the whole dorsal and anterior region of the body in front of the pericardium. The genital ducts of the Polyplacophora have the same arrangement as the renal nephridia, bent slightly forward. They are not directly continuous with the wall of the gonadial cavity, which they place in communication with the exterior; but each commences by a large ciliated funnel; they are, in fact, an anterior pair of nephridia, like the genital ducts of the Cephalopoda. The Chitons are therefore no less primitive in this respect than Molluscs the gonads of which open to the interior of the renal nephridia; on the contrary they are more primitive than most Mollusca, as having retained two pairs of nephridia, the anterior serving as gonaducts. The genital opening is slightly in front of the renal; between the two are one or more pairs of branchiae (at most, nine, in *Cryptoplax larvaformis*). In the Aplacophora the generative organs open into the pericardium; the nephridia thus serve as genital ducts, and exhibit accessory glands in their course; they often unite into a single median aperture in the cloacæ (*Neomeniidae*). With regard to the nervous system, in addition to anastomoses between the pedal cords, there are in the majority of species pallio-pedal anastomoses between the pedal and pallial cords of the same side. Further, in certain Aplacophora (*Chetoderma* and *Paramenia*) the pallial and pedal cords of the same side unite posteriorly into a single cord. The two lateral cords always unite posteriorly above the rectum, often producing a ganglionic swelling. There is no visceral commissure; the generative and renal glands and heart are innervated from the pallial cords. The labial or infra-oesophageal commissure of Polyplacophora gives rise to a stomato-gastric commissure, the two branches of which unite above and below the alimentary canal; and also to a second infra-oesophageal or subradular commissure with ganglia and sense-organs, which lies in front of the radula. This labial commissure, with subradular commissure and organs, corresponds to the parts of the same name in Scaphopoda and Cephalopoda. In addition to the subradular organ, adult Chitonids sometimes have pallial eyes (see above), and generally an osphradium on each side, not one at the base of each tentidium. This organ is a sensitive spot on the inner face of the mantle outside the branchial region, near the largest branchia, and innervated from the pallial cord.

In the Polyplacophora (16, 17) the embryo becomes a trochophore with apical ciliary

FIG. 2.—Embryo of *Yoldia limatula*, about 70 hours old (Drew).

tuft in the centre of the velar ring; its large and long foot-gland [byssus-gland] atrophies in the adult. The dorsal cuticle calcifies to form the shell-plates, of which often only the anterior seven are found at first. In each lateral groove, immediately behind the velum, is a larval eye corresponding to the cephalic eye of *Lamellibranchia* (18). In the *Neomenioidea* (19) the ova develop into an invaginate gastrula which becomes a trochophore with posterior blastopore, anterior ciliated ring on the velum, and central apical flagellum. The external surface of the trochophore is formed of ciliated "test cells," which ultimately disappear, as in *Yoldia* (Fig. 2); beneath them is formed the future mantle. On the trochophore becoming a larva, spicules appear under the mantle, and the dorsal face is covered by seven imbricated calcareous plates, formed by apposed flattened spicules (Fig. 3, C).

The Polyplacophora present the most archaic characters among the Amphineura; the Aplacophora, on the contrary, are the more specialized in the following points—(1) the reduction of the foot; (2) the disappearance of the shell (one of the Polyplacophora shows how these two reductions result simultaneously); (3) the loss of the anterior nephridia; (4) the absence of the radula in several forms.

Branch Prorhipidoglossomorpha.—These organisms are characterized by the presence of a visceral commissure in the nervous system, and by the absence of genital nephridio-ducts; the gonads open either into the kidneys, or more or less close to their external apertures, by means of ducts formed at the expense of part of the renal nephridia.

Class II. Gastropoda.—Their essential character is a loss of asymmetry, produced by torsion of the visceral sac. This torsion may be resolved into two successive movements—the first is a ventral flexure in the antero-posterior or sagittal plane; the result of this is to approximate the two ends of the alimentary canal. In development, the openings of the mantle-cavity and the anus are always originally posterior; later they are brought forward ventrally. During this first movement flexure is also produced by the coiling of the visceral sac and shell; primitively the

latter was bowl-shaped; but the ventral flexure, which brings together the two extremities of the digestive tube, gives the visceral sac the outline of a more or less acute cone. The shell necessarily takes this form also; and then becomes coiled in a dorsal or anterior plane—that is to say, it becomes exogastric. This condition may be seen in embryonic *Patellidae*, *Fissurellidae*, and

FIG. 3.—*Dondersia banquensis* (Pruvot). A, larva of 36 hours; B, larva of 100 hours; C, young animal of 7 days.

Trochidae, and agrees with the method of coiling of a Mollusc without lateral torsion, such as *Nautilus*. But ultimately the coil becomes ventral or endogastric, in consequence of the second torsion movement then apparent, the first being inadequate to approximate the two extremities of the digestive tract. The elongation for crawling of the ventral surface, which primitively was very short, not only prevents the approximation of these two extremities, but actually tends to separate them. The second movement is therefore a lateral torsion of the visceral mass, which forcibly effects this approximation; the foot remaining a fixed point, this torsion occurs in a plane approximately at right angles to that of the first movement, and carries the pallial aperture and the anus from behind forwards. If, at this moment, the animal were placed with mouth and ventral surface turned towards the observer, this torsion carries the circumanal complex in a clockwise direction (along the right side in dextral forms) through 180° as compared with its primitive condition. The (primitively) right-hand organs of the complex thus become left-hand, and *vice versa*. The visceral commissure, while still surrounding the digestive tract, becomes looped; its right half, with its proper ganglion, passes to the left side over the dorsal face of the alimentary canal (whence the name supra-intestinal), while the left half passes below towards the right side, thus originating the name infra-intestinal given to this half and to its ganglion. Next, the shell, the coil of which was at first exogastric, being also entangled in this rotation through 180°, exhibits an endogastric coiling. This, however, is not generally retained in one plane, and the spire projects, little by little, on the side which was originally left but finally becomes right (in dextral forms, with a clockwise direction, if viewed from the side of the spire; but counter-clockwise in sinistral forms). The direction of involution of the shell thus corresponds to that of the lateral torsion. Finally, the original symmetry of the circumanal complex vanishes; the anus leaves the centre of the pallial cavity and passes towards the right side (left side in sinistral forms); the organs of this side become atrophied and disappear. The essential feature of the asymmetry of Gastropoda is the atrophy or disappearance of the primitively left half of the circumanal complex (the right half in sinistral forms), because the direction of coiling is in relation both to that of the asymmetry and to that of the torsion; the sinistral involution corresponds exactly to a *situs inversus viscerum* of a Gastropod with dextral coil (*Physa*, *Clausilia*, *Triforis*, &c.). But there are forms in which the involution is "hyperstrophic," that is to say, the turns of the spire projecting but slightly, the spire, after flattening out gradually, finally becomes re-entrant and transformed into a false umbilicus; at the same time that part which corresponds to the umbilical of forms with a normal coil, projects and constitutes a false spire; the coil thus appears to be sinistral, although the asymmetry remains dextral, and the coil of the operculum (always the opposite to that of the shell) sinistral (*Lanistes* among Streptoneura, *Limacinidae* among Opisthobranchia). The same, *mutatis mutandis*, may occur in sinistral shells.

The characteristic torsion attains its maximum effect among the majority of Streptoneura. It is followed in some specialized "Heteropoda" and in the Euthyneura by a torsion in the opposite direction or detorsion, which brings the anus farther back, and untwists the visceral commissure (see Euthyneura, below). This conclusion has shown that the Euthyneura do not represent an archaic form of Gastropoda, but are themselves derived from streptoneurous forms. The difference between the two subclasses has been shown to be slight; certain of the more archaic Tectibranchia (*Actæon*) and Pulmonata (*Chilina*) still have the visceral commissure long and not untwisted. The fact that all the Euthyneura are hermaphrodite is not a fundamental difference;

several Streptoneura are so likewise (Valvata, Onchidiopsis, Mar-senina, Odostomia, Bathysciadium, Entoconcha).

Subclass A. STREPTONEURA.—The old division into Zygo-branchia and Azygobranchia must be abandoned, for the Azygo-branchiate Rhipidoglossa have much greater affinity to the Zygobranchiate Haliotidae and Fissurellidae than to the Azygo-branchia in general, properly so called. This is shown by the labial commissure and pedal cords of the nervous system, by the opening of the gonad into the right kidney, and by other points. Further, the Pleurotomariidae have been discovered to possess two branchiae.

Order I. *Scutibranchia*.—A general symmetry of the nephridia and auricles; pedal cords with multiple anastomoses; bipectinate ctenidia; the genital products escape to the exterior by the right nephridium (except Helicinidae). Suborder A. *Docoglossa*. Radula with the lateral teeth few in number, generally beam-shaped; the heart is not traversed by the rectum, and has but one auricle. Families: Acmaeidae, Patellidae, Lepetidae, Bathysciadiidae. Suborder B. *Rhipidoglossa*. Radula with numerous lateral teeth, disposed in a fan; heart traversed by the rectum, and provided with two auricles. Families: Pleurotomariidae, Fissurellidae, Haliotidae, Trochidae, Stomatellidae, Delphinulidae, Turbinidae, Neritidae, Titiscantiidae, Helicinidae.

The bipectinate branchiae are only paired in Pleurotomaria, Fissurellidae, and Haliotidae. In Scissurella the right branchia is only monopectinate; in other cases it is absent (Acmaea, Trochus, Nerita, &c.); but the left is always bipectinate in them. In the Helicinidae, which are terrestrial and physiologically Pneumochlamydate although morphologically Rhipidoglossate, there is neither branchia nor osphradium, but the pallial chamber with a large opening serves as a lung. The shell which at times is largely overspread by the mantle in certain Fissurellidae, is entirely internal in Pupilia, and absent from Titiscantiidae. Each pleural ganglion anastomoses with the opposite half of the visceral commissure by its pallial nerve (dialyneury) in the Rhipidoglossa, but not in the Docoglossa. The gonad opens into the right kidney, connexion being made through a permanent opening or a papilla, at any rate in various Rhipidoglossa; but the Neritidae have lost the right kidney, and consequently have an external generative opening. The trochosphere has a shell which is at first exogastrically coiled, and has a posterior pallial chamber; torsion commences late.

Order II. *Pectinibranchia*.—One branchia only present; monopectinate (except in Valvata); gonad opening to the exterior by its own duct. The former classification into Holo-chlamyda, Pneumochlamyda, and Siphonochlamyda must be abandoned, as the Pneumochlamyda and Siphonochlamyda are polyphyletic; the Helicinidae in particular can no longer be retained in the former, as being Scutibranchia Rhipidoglossa, with close affinity to the Neritidae. Suborder A. *Taenioglossa*. Radula with three rows of teeth on each side of the median. This suborder includes two groups:—1. Platypoda (Reptantia), comprising the great majority of the families of Streptoneura; 2. Heteropoda (Natantia), containing the families Atlantidae, Carinariidae, Pterotracheidae. Suborder B. *Stenoglossa*. The radula narrow, with only one lateral tooth on each side, in each transverse row; all are siphonate. Group 1. *Rhachiglossa*. With a median tooth. Families: Fasciolaridae, Turbinellidae, Mitridae, Buccinidae, Haliidae, Muricidae, Coralliophilidae, Cancellariidae, Volutidae, Olividae, Harpidae, Marginellidae. Group 2. *Toxiglossa*. No median tooth. Families: Conidae, Terebridae, Pleurotomatidae.

Throughout, the pleural ganglia anastomose with the opposite half of the visceral commissure, or even with the corresponding ganglion, by a longer or shorter connective. In the more primitive Taenioglossa the osphradium is only a filiform prominence of epithelium (Littorina, Fig. 4); by further specialization it may develop pectinations on both sides, which may even be arborescent (Pteroceras, Cypreae). It is absent from the Pulmonate forms; in one of these (Cerithidea) it is replaced by a pallial eye, of structure analogous to those of Onchidium and the Pectinidae. There are two larval nephridia—closed sacs in marine Pectinibranchia, tubes with an external opening in Paludina and Bithynia. The adult kidney develops at the expense of the coelomic (pericardial) epithelium. In Paludina traces of the left kidney are recognizable, but atrophy, the ducts becoming the genital duct. The genital gland is formed in mesoderm as a coelomic region separate from the pericardium (Paludina). The branchia is formed by folds on the internal surface of the mantle. In pelagic Streptoneura (Heteropoda) we may observe a detorsion and return to an external symmetry concurrently with a retrogressive evolution of the shell, which is paralleled by Opisthobranchia: the Atlantidae have a coiled and well-developed shell, an operculum, and prosobranchialism; the Carinariidae, an uncoiled and diminished shell, and no operculum; the Pterotracheidae, no shell and opisthobranchialism, or even abbranchialism in Firoloida. The foot is laterally compressed, and carries a sucker in the middle line (in the male only, among Pterotracheidae). In the nervous system the pleural ganglia are coupled to the cerebral and not to the pedal centres; there is no dialyneury, but visero-pedal anastomoses connect the right

pedal ganglion with the infra-intestinal, and the left with the supra-intestinal. In Carinariidae and Pterotracheidae the eyes are very voluminous, the retina of small extent, with rods arranged in grooves perpendicular to the optic axis.

Subclass B. EUTHYNEURA.—Among the essential characters which discriminate these from the Streptoneura, is notable not an absence of torsion, but an actual detorsion of the visceral commissure. In several of the more primitive forms (Actaeonidae and

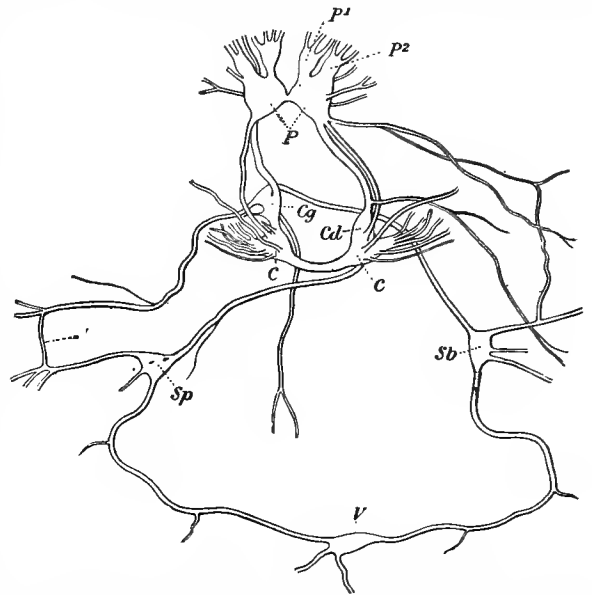

FIG. 4.—Littorina, dorsal view of nervous system (Bouvier): p^1 , p^2 , accessory pedal ganglia; P, pedal ganglia; Cg, left pleural ganglion; Cd, right pleural ganglion; c, cerebral ganglia; Sp, supra-intestinal ganglion; Sb, sub-intestinal ganglion; V, abdominal ganglion; Z, dialyneuric anastomosis.

Limacinidae among Opisthobranchia, Chiliniidae among Pulmonata) the same torsion occurs as in Streptoneura: prosobranchialism (Actaeon), a looped visceral commissure (Actaeon = Tornatella, Chilina, and even slightly still in Bulla and Scaphander), the osphradium to the left, innervated from the supra-intestinal ganglion (Actaeon, Limacina). This untwisting of the visceral commissure is the result of a general untwisting which gradually restores the anus and circumanal complex from the anterior region to the right side (Bulla, Aplysia), or even to a posterior position (Onchidium, Philine, straight Pteropoda, Thecosomata, Cavolinia, Clio, &c.).

In the latter the detorsion is complete, and consists in a rotation of 180° in a direction counter to the original Gastropod torsion; it carries the pallial cavity on to the ventral surface by way of the right-hand side, and from this results in "straight Pteropods" the loop of the genital duct round the alimentary tract. An operculum is retained by the adult not only of Actaeon, but also in Limacinidae, Ringiculidae, and Amphibolidae (Pulmonata). The subclass contains two orders.

Order I. *Opisthobranchia*.—The order contains two sections only, Tectibranchia and Nudibranchia; the old Phyllidiobranchia being united with the latter; indeed, the Phyllidia are Dorids, and the Pleurophyllidia are Eolids.

Section 1. *Tectibranchia*.—Characterized by the presence of a ctenidium and the asymmetry of their external form. Suborder A. *Bulloida* (including Pteropoda Thecosomata). Pallial cavity well developed. Families: Actaeonidae, Ringiculidae, Tornatinidae, Scaphandriidae, Philinidae, Peltidae, Lophoceridae, Limacinidae, Cymbuliidae, Cavoliniidae (the three last forming the old Pteropoda Thecosomata). Suborder B. *Aplysioida*. Pallial cavity greatly reduced or absent; parapodia not continuous with the sole of the foot. Families: Aplysiidae, and the four families of Pteropoda Gymnosomata—Pneumonodermatidae, Notobranchiidae, Clionidae, Halopsychidae. Suborder C. *Pleurobranchioida*. Pallial cavity absent; no parapodia. Families: Umbrellidae, Pleurobranchiidae.

Section 2. *Nudibranchia*.—Characterized by the absence of ctenidia, and their external symmetry. Suborder A. *Tritonioida*. Holohepatic, with anus on the right side. Families: Tritoniidae, Scyllidae, Phyllirhoide, Thetyidae. Suborder B. *Doridoidea*. Holohepatic, with anus, median, and posterior. Families: Polyceratidae, Dorididae, Doridosidae, Corambidae, Phyllidiidae. Suborder C. *Eolidoida*. Cladohepatic, with simple oviduct. Families: Eolididae, Glaucidae, Pleurophyllidiidae, Dotonidae, Proctonotidae, Fionidae. Suborder D. *Elysioidea*. Cladohepatic, with bifurcated oviduct. Families: Hermaeidae, Elysiidae, Limpontiidae (Fig. 5).

The borders of the solar face of the foot are often produced into fins or "parapodia," to be distinguished from the epipodia of the Aspidobranchia which are outgrowths of the sides of the foot and not of its ventral surface. These parapodia, which are greatly developed in *Acera* and *Gastropteron* among *Bulloida*, may even form a contractile sac right round the body (*Notarchus*) and constitute the fins of many *Pteropoda*. The ctenidium is generally a lamina plicated in two directions alternately, and not a bipectinate appendage as in *Streptoneura* *Aspidobranchia*. It is absent from *Nudibranchia*, even from *Dorida*, the peri-anal leaf-like gills of which are homodynamous with the dorsal appendages of *Tritonioida*. Prosobranchialism occurs in *Actæon*, *Limacina*, &c., as in the *Streptoneura*. The hepatic cæca in the dorsal papillæ of *Eolidoida* actually communicate with the endogenous sacs at their extremity; endocysts are absent from *Eolis glaucoides*. The nervous system is concentrated dorsally in *Pleurobranchioida* and *Nudibranchia*, but ventrally in *Pteropoda* *Thecosomata*. The osphradium is absent from *Nudibranchia*, in which there is an increase of the tentacular

FIG. 5.—*Limapontia nigra*, generative organs (Hancock): a, penis; d, albuminiferous gland; h, hermaphrodite follicles; j, oviduct; k, mucous oviducal gland; l, oviducal opening; m, prostate; n, vaginal opening; q, receptaculum seminis.

olfactory organ (rhinophore); it is, however, retained by all *Pteropoda* *Gymnosomata*, although they generally lack a ctenidium.

The free veliger of *Nudibranchia* is followed by a crecpiplanariform stage which shortly loses its shell, and ultimately acquires dorsal papillæ, beginning with the anterior. In *Cenia* (*Elystoida*) the young leave the egg in the adult shape; there exists in this case, as in *Pelta*=*Runcina* among *Tectibranchia*, neither free veliger nor embryonic shell, these being the sole examples known among *Opisthobranchia*; all the others have a larval shell, even the *Pteropoda* *Gymnosomata*, with the possible exception of *Theceurybia*=*Halopsyche*.

The phylogenetic relations between *Nudibranchia* and *Tectibranchia* become clear through the organization of the *Pleurobranchioida*; in these there is neither pallial chamber nor osphradium, and respiration is largely pallial; the shell may be entirely absent (*Pleurobranchia*); the nervous system is concentrated dorsally; spicules and endocysts exist in the dorsal integuments. The mantle of *Doridoida* is quite homologous with that of *Pleurobranchioida*, and in no case with an epipodium reflected dorsally over the surface of the body.

Order II. *Pulmonata*.—(For the definition the article in vol. xvi.

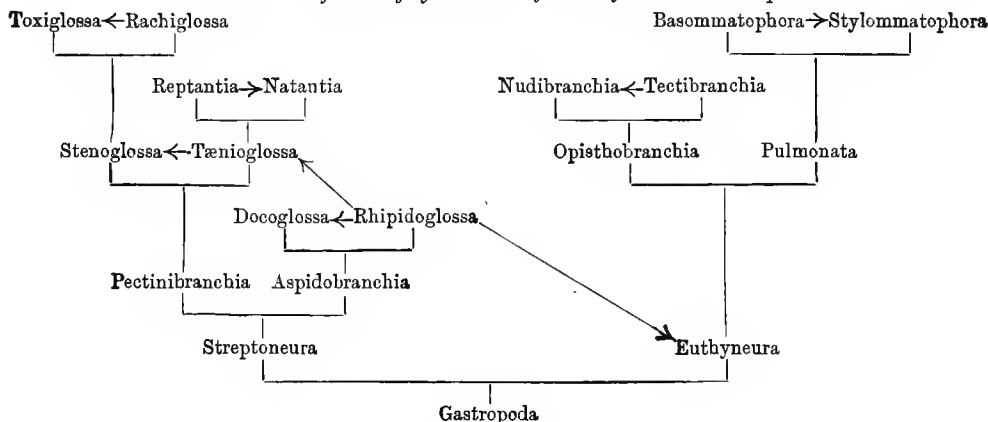

of this work should be consulted.) Suborder I. *Basommatophora*. Families: *Auriculidæ*, *Amphibolidæ*, *Siphonariidæ*, *Chilimidæ*, *Limnæidæ*, *Planorbidæ*, *Physidæ*. Suborder II. *Stylommatophora*. The various slugs do not form a homogeneous group, but are polyphyletic. Families: *Succineidæ*, *Athoracophoridæ*, *Pupidæ*, *Helicidæ*, *Philomycidæ*, *Arionidæ*, *Limacidæ*, *Testacellidæ*, *Vaginulidæ*, *Onchidiidæ*.

The *Pulmonate* ventricle is generally at the back of the heart; this is explicable by the descent of *Pulmonata* from very primitive *Tectibranchia*, highly twisted forms alone carrying the ventricle behind (*Testacella*, *Onchidium*). The lung, which in the majority of cases is vascular, is tracheal in the *Athoracophoridæ*. Among *Stylommatophora*, this organ is reduced in *Onchidiidæ* (the marine forms of which acquire branchial mantle tufts dorsally) and absent in *Vaginulidæ*. Among *Basommatophora*, in addition to *Limnæa* of deep lakes the following admit water to the lung:—of marine forms, *Amphibola*, *Gadinia*, *Siphonaria* (this acquires a new pallial intrapulmonary gill); and of fresh-water forms, *Chilina* and *Planorbis nautilus*. Other fresh-water *Basommatophora* develop a pallial extrapulmonary gill (*Planorbis corneus*, *Pulmonobranchia* (Fig. 6), *Ancylus*, the latter having lost all trace of a lung-cavity). The kidney almost invariably, notably among *Stylommatophora*, has a distinct ureter, opening more or less closely to the lung-aperture, sometimes at the extremity of the rectum. In *Pythia* of the *Auriculidæ*, the sperm-duct is an open furrow from the hermaphrodite opening to the penis; in other members of the same family it is tubular, and the bifurcation of the hermaphrodite duct occurs at some distance from the female opening, representing the primitive hermaphrodite opening. The penis is apparently innervated from the cerebral centre, but in fact from the pedal ganglion. In some less specialized *Basommatophora* the nervous system still exhibits a long commissure; it is even slightly looped in *Chilina*. An osphradium occurs in development, even among *Stylommatophora* (*Helix*, *Limax*); among these, however, it is always on the right in dextral species, as is the vestigial osphradial ganglion of *Auricula*. The velum is vestigial, except in *Auriculidæ*, *Siphonariidæ*, *Amphibolidæ*, and *Onchidiidæ*, where it is well developed. These families possess a larval operculum, retained till the adult stage by *Amphibola*. The eyes and part of the cerebral centres develop as ectodermal invaginations; these cerebral cavities are preserved in adult *Limnæa* and *Planorbis*. In *Clausilia* and *Succinea* the shell arises in a sac which at first is entirely closed. The embryonic nephridia are bent tubes, which open to the exterior and terminate internally by a funnel with flame-cell. In the *Basommatophora* three perforated cells constitute the canal, a fourth forms the funnel.

FIG. 6.—*Pulmonobranchia lamellata*, with mantle partially cut out above the pulmonary opening and the gill.

Tabular View of the Phylogenetic Classification of the Class Gastropoda.

Class III. *Scaphopoda*.—The *Scaphopoda* have no ctenidia. The cephalic filaments or captacula are outgrowths of the paired dorsal cephalic lobes. The circulatory system has neither vessels nor well-developed muscular walls to the ventricle. The kidneys have no pericardial orifices; the genital gland opens into the right kidney. The nervous system exhibits two pleural ganglia, each with cerebro-pleural and pleuro-pedal connectives, the latter

fusing immediately with the cerebro-pedal, as in *Nucula*. An infracesophageal labial commissure gives origin to a stomatogastric commissure (as in *Aspidobranchia* and *Polyplacophora*), and innervates a sensory subradial organ. The ova are laid singly, and segmentation is irregular; invagination produces a gastrula with large blastopore originally at the posterior end of the embryo. The latter elongates, and acquires anteriorly a tuft of cilia, sur-

rounded by four circles of cilia, to form the velum. The blastopore remains open, and draws gradually towards the anterior end along the ventral surface. On the dorsal aspect spring two lateral pallial ridges, parallel and symmetrical; these stretch towards the ventral surface, where they finally fuse to form a tubular mantle round the body. The shell which this mantle secretes, at first cup-shaped, little by little assumes the form of a tube, like the mantle, by union of its margins. On the ventral surface the foot appears as a prominence; this becomes elongated anteriorly, and by its aid the animal can crawl after the disappearance of the velum. The cerebral ganglia arise as two ectodermal invaginations in the velar area; the otcocysts by invagination at the surface of the foot; and the pedal ganglia, after the otcocysts, by ectodermal thickenings. The anus is perforated very late. After five or six days the velum atrophies, and the embryo begins to crawl. Families: Dentaliidae, Siphonodentaliidae.

Class IV. **Lamellibranchia**.—The old classification, founded on the number of adductor muscles, can no longer be retained, the "Monomya" being polyphyletic. The degree of specialization attained by different forms is well shown by the structure of the branchiae (ctenidia); using these, five orders may be distinguished.

Order 1. **Protobranchia**.—Branchial filaments short, not flexed, not united by junctions, arranged in two series in opposite directions. Families: Nuculidae, Solenomyidae.

Order 2. **Filibranchia**.—Branchial filaments elongated, parallel, flexed, and united together by ciliary junctions. Families: Anomiidae, Arcidae, Trigonidae, Mytilidae.

Order 3. **Pseudolamellibranchia**.—Branchial filaments with interfoliate junctions (vascular or connective); branchiae plicated; posterior adductor muscle reduced or wanting; foot slightly developed. Families: Aviculidae, Ostræidae, Pectinidae, Dimyidae.

Order 4. **Eulamellibranchia**.—Branchiae with interfilamentar and interfoliar unions, all of which are vascular; mantle lobes united posteriorly at one or two points. This order includes the great majority of families, which are distributed among seven sub-orders: Submytilacea, Tellinacea, Veneracea, Cardiacea, Myacea, Pholadacea, and Anatinacea.

Order 5. **Septibranchia**.—Branchiae transformed into a muscular septum, which stretches from the anterior adductor to the separation of the two siphons, and surrounds the foot. Families: Poromyidae, Cuspidariidae.

As in other Mollusca, the edges of the mantle can be reflected over (Galeomma, Entovalva), or can even entirely conceal the shell, which is absolutely internal in three genera, Chlamydoconcha, Ehippodonta, and Scioberetia. In the last the adductor muscles are absent, as in Aspergillum. Both adductors are embryonically developed in all Lamellibranchs, the anterior appearing always first, even in cases where it ultimately disappears. The retractor muscles of the foot correspond to the columellar muscle of Gastropoda. The foot has a ventral disc only in Protobranchia and Pectunculus; in other forms it exhibits very generally a cavity, the cells of which secrete a byssus for fixation of the animal. The liver occasionally presents an asymmetry, the left lobe being in such cases the larger (Nuculidae). The epithelial covering of the auricles often constitutes pericardial glands; other portions of the wall of the pericardium may penetrate into the mantle. In the Septibranchia, by abnormal development of their muscular elements, the branchiae form a muscular septum with symmetrical orifices; respiration is effected by the internal surface of the mantle, over which the contractions of the septum force a powerful current of water. The two nephridia communicate with one another; they extend sometimes into the mantle. The genital glands also communicate with one another in many forms; and in some cases open into the kidneys. Many species are hermaphrodite, but while in some (e.g., Ostræa, Cardium) ova and spermatozoa arise side by side throughout the extent of the gland, in others (e.g., Pecten) male and female portions are distinct; and in Poromya and Anatinacea there exist a pair of ovaries and a pair of testes entirely distinct, each with its proper orifice.

In the more archaic forms (Protobranchia) the pleural ganglia are distinct, as in Gastropoda and Scaphopoda; they are coupled to the cerebral, each giving rise to a pallial nerve, and a pleuro-pedal connective more or less promptly united to a cerebro-pedal connective. The existence of the pleural ganglia shows that no other visceral centre is fused with the cerebral, and that these are the posterior centres which correspond to the visceral ganglia of other Mollusca. The otcocysts remain open to the exterior in some adult Nuculidae. The cephalic eyes observable in various larvæ are retained in some adults on the anterior region of the branchial axis (Mytilus, Avicula, Fig. 7). A unique structure characterizes the pallial eyes of Pectinidae and of some species of Cardium.

The ova are laid separately (except in Nucula delphinodonta). A large number of Lamellibranchia retain the developing eggs in the branchial lamellæ (Submytilacea, and fresh-water forms, except Dreissensi). Larval nephridia have been detected in several

sub-groups, consisting of a deep canalicular portion, and a superficial portion which opens to the exterior postero-ventrally of the head; the lumen is intracellular, with a flame cell.

In the Unioniidae the larva (Glochidium) is temporarily parasitic, and encysts in the skin of a fish, deriving sustenance by means of the ectodermal cells of the mantle from the epidermis of the host. Parasitic life lasts from two to five weeks.

Class V. **Cephalopoda**.—For definitions of the divisions, the article in vol. xvi. of this work should be consulted.

Subclass A. **TETRABRANCHIA**.

—This contains a single living genus, Nautilus, and numerous fossil genera (see article CEPHALOPODA).

Subclass B. **DIBRANCHIA**.

Order 1. **Decapoda**.—Suborder (a) **Ægopsida**, with seven living families: Spirulidae, Ommatostrephidae, Physanoteuthidae, Onychoteuthidae, Gonatidae, Chiroteuthidae, Cranchiidae. Suborder (b) **Myopsida**. Families: Sepioidae, Idiosepiidae, Sepiidae, Loliginidae, Sepiidae.

Order 2. **Octopoda**.—Families: Cirrhotenthidæ, Octopodidæ, Argonautidæ, Philonexidæ. The internal shell is greatly reduced; it is purely chitinous in all Octopoda, forming an unpaired piece in Cirrhotenthis, a pair of stylets in Octopus. In Argonauta alone the shell gland shallows out, without closing. In the Decapoda some allies of Sepioida are also shell-less. The tentacular arms atrophy in various Ægopsida. The hectocotylized arm belongs generally to the fourth pair in Decapoda, that of the left side only (Ommatostrephidae, Onychoteuthidae, and most Myopsida), or on both sides (Idiosepius, Spirula, Fig. 8). In Nautilus the spadix may be right or left. Some deep-water Ægopsida possess luminous organs. The radula is absent from Cirrhotenthis; the ink-sac is also wanting in this genus and in some species of Octopods. In Octopoda the pericardial part of the cœlum is wanting. The cœlum includes only the genital capsule, which communicates with the capsules of the branchial hearts by long canals (absent in two families). The appendices of the branchial hearts are the morphological equivalent of the "pericardial glands" of other Mollusca; their glandular wall is excretory. The nervous system presents the same labial commissure as do Amphineura and Prohipidoglossomorpha. The osphradium of Nautilus is placed against and protected by the interbranchial papilla. Certain pigmented organs of Cirrhotenthis are supposed to be thermoscopic. In those Octopoda in which the hectocotylus is not autotomous, it is intruded into the pallial cavity of the female so as to introduce spermatozoa into the distal portion of the oviduct (Octopus); both arms of the dorsal pair in Sepioida place the spermatozoa in the neighbourhood of the female opening.

FIG. 8.—*Spirula peronii* (Huxley and Pelseener): F, F', fins; Pd, dorsal anterior mantle-lobe; T, of the crystalline lens has a separate right tentacular arm; origin from the internal portion. The I', I'', I''', left arms; blastoderm of the egg forms the ectoderm; the primitive endoderm takes origin at the periphery of the ectoderm, spreading under and away from it, enclosing the yolk with a layer of large nuclei at its surface to form the perivitelline membrane. The remainder of the endoderm is in great measure transformed into the mesoderm. The primitive endoderm being unable to surround itself with ectoderm to form a gastrula, the definitive endoderm appears rather late in development; a furrow of cells below the hinder part of the mantle in the middle line, derived, like the perivitelline membrane, from the primitive endoderm, gives rise to stomach, liver, and intestine.

Molsheim, an ancient town of Germany, in the province of Alsace-Lorraine, known in the 9th century as Molleshem, and formerly the seat of a famous Jesuit college, which in 1701 was removed to and united with the University of Strassburg. It has now manufactures of bayonets, swords, and hardware. Population, 4000.

Moltke, Helmuth Carl Bernhard, Count von (1800-1891), Prussian field-marshal, for thirty years chief of the staff of the Prussian army, the greatest strategist of the latter half of the 19th century, and the creator of the modern method of directing armies in the field, was born 26th October 1800, at Parchim in Mecklenburg, of a German family of ancient nobility. His father in 1805 settled in Holstein and became a Danish subject, but about the same time was impoverished by the burning of his country house and the plunder by the French of his town house in Lübeck, where his wife and children were. Young Moltke therefore grew up in straitened circumstances. At the age of nine he was sent as a boarder to Hohenfelde in Holstein, and at the age of eleven to the cadet school at Copenhagen, being destined for the Danish army and court. In 1818 he became a page to the king of Denmark and second lieutenant in a Danish infantry regiment. But at twenty-one he resolved to enter the Prussian service, in spite of the loss of seniority. He passed the necessary examination with credit, and became second lieutenant in the 8th Infantry Regiment stationed at Frankfort-on-the-Oder. At twenty-three, after much less than the regulation term of service, he was allowed to enter the general war school, now the war academy, where he studied the full three years and passed in 1826 a brilliant final examination. He then for a year had charge of a cadet school at Frankfort-on-the-Oder, after which he was for three years employed on the military survey in Silesia and Posen. In 1832 he was seconded for service on the general staff at Berlin, to which in 1833 on promotion to first lieutenant he was transferred. He was at this time regarded as a brilliant officer by his superiors, and among them by Prince William, then a lieutenant-general, afterwards king and emperor. He

was well received at court, and in the best society of Berlin. His tastes inclined him to literature, to historical study and to travel. In 1827 he had published a short romance, *The Two Friends*. In 1831 it was followed by an essay entitled *Holland and Belgium in their Mutual Relations, from their Separation under Philip II. to their Reunion under William I.*, in which were displayed the author's interest in the political issues of the day, and his extensive historical reading. In 1832 appeared *An Account of the Internal Circumstances and Social Conditions of Poland*, a second study of a burning question based both on reading and on personal observation of Polish life and character. In 1832 he contracted to translate Gibbon's *Decline and Fall* into German, for which he was to receive £75, his object being to earn the money to buy a horse. In eighteen months he had finished nine volumes out of twelve, but the publisher failed to produce the book and Moltke never received more than £25, so that the chief reward of his labour was the historical knowledge which he acquired. He had already found opportunities to travel in South Germany and Northern Italy, and in 1835 on his promotion as captain he obtained six months' leave to travel in South-Eastern Europe. After a short stay in Constantinople he was requested by the Sultan to enter the Turkish service, and being duly authorized from Berlin he accepted the offer. He remained two years at Constantinople, learned Turkish and surveyed for the Sultan the city of Constantinople, the Bosphorus, and the Dardanelles. He travelled in the Sultan's retinue through Bulgaria and Rumelia, and made many other journeys on both sides of the Strait. In 1838 he was sent as adviser to the Turkish general commanding the troops in Armenia, who was to carry on a campaign against Mehemet Ali of Egypt. During the summer he made extensive reconnaissances and surveys, riding several thousand miles in the course of his journeys, navigating the dangerous rapids of the Euphrates, and visiting and mapping many districts where no European traveller had preceded him since Xenophon. In 1839 the army moved south to meet the Egyptians, but upon the approach of the enemy the general became more attentive to the prophecies of the mollahs than to the advice of the Prussian captain. Moltke resigned his post of staff officer and took charge of the artillery, which therefore, in the ensuing battle of Nisib, was the last portion of the Turkish army to run away. The Turks were well beaten and their army dispersed to the four winds. Moltke with infinite hardship made his way back to the Black Sea, and thence to Constantinople. His patron Sultan Mahmoud was dead, so he returned to Berlin, where he arrived, broken in health, in December 1839. When he left Berlin in 1834 he had already "the courtier's, soldier's, scholar's eye, tongue, sword." When he returned it was with a mind expanded by a rare experience, and with a character doubly tempered and annealed. While away, he had been a constant letter-writer to his mother and sisters, and he now revised and published his letters as *Letters on Conditions and Events in Turkey in the Years 1835 to 1839*. No other book gives so deep an insight into the character of the Turkish Empire, and no other book of travels better deserves to be regarded as a German classic. One of his sisters had married an English widower named Burt, who had settled in Holstein. Her step-daughter, Mary Burt, had read the traveller's letters, and when he came home as a wooer was quickly won. The marriage took place in 1841, when Mary was just turned sixteen. It was a very happy union, though there were no children, and Moltke's love-letters and letters to his wife are among the most valuable materials for his biography. On his return in 1840 Moltke had been appointed to the staff of the 4th army corps, stationed at Berlin; he was promoted major on his

wedding day. The fruits of his Eastern travels were by no means exhausted. He published his maps of Constantinople, of the Bosphorus, and of the Dardanelles, and, jointly with other German travellers, a new map of Asia Minor and a memoir on the geography of that country, as well as a number of periodical essays on various factors in the Eastern Question. In 1845 appeared *The Russo-Turkish Campaign in Europe, 1828-29, described in 1845 by Baron von Moltke, Major in the Prussian Staff*, a volume which was recognized by competent judges as a masterpiece of military history and criticism. Moltke at this period was much occupied with the development of railways. He was one of the first directors of the Hamburg-Berlin railway, and in 1843 published a review article entitled *What Considerations should determine the Choice of the Course of Railways?* which reveals a mastery of the technical questions involved in the construction and working of railway lines.

In 1845 Moltke was appointed personal adjutant to Prince Henry of Prussia, a Roman Catholic who lived at Rome. He thus had the opportunity of a long stay in the Eternal City, with no more than nominal duties to perform. It was a life which he and his wife much enjoyed, and he spent much of his leisure in a survey, of which the result was a splendid map of Rome, published at Berlin in 1852. In 1846 Prince Henry died, and Moltke was then appointed to the staff of the 8th army corps at Coblenz. In 1848, after a brief return to the great general staff at Berlin, he became chief of the staff of the 4th army corps, of which the headquarters were then at Magdeburg, where he remained seven years, during which he rose to lieutenant-colonel (1850), and colonel (1851). In 1855 he was appointed first adjutant to Prince Frederick William (afterwards crown prince and emperor), whom he accompanied to England on his betrothal and marriage, as well as to Paris and to St Petersburg to the coronation of Alexander II. of Russia. Prince Frederick William was in command of a regiment stationed at Breslau, and there as his adjutant Moltke remained for a year, becoming major-general in 1856. On the 23rd of October 1857, owing to the serious illness of King Frederick William IV., Prince William became prince regent. Six days later the regent selected Moltke for the then vacant post of chief of the general staff of the army. The appointment was made definitive in January 1858. Moltke's posthumously published military works disclose a remarkable activity, beginning in 1857, devoted to the adaptation of strategical and tactical methods to changes in armament and in means of communication, to the training of staff officers in accordance with the methods thus worked out, to the perfection of the arrangements for the mobilization of the army, and to the study of European politics in connexion with the plans for campaigns which might become neces-

sary. In 1859 came the war in Italy, which occasioned the mobilization of the Prussian army, and as a consequence the reorganization of that army, by which its numerical strength was nearly doubled. The reorganization was the work not of Moltke but of the king, and of Roon, minister of war; but Moltke watched the Italian campaign closely, and wrote a history of it, published in 1862, and attributed on the title-page to the historical division of the Prussian staff, which is the clearest account of the campaign and contains the best criticism upon it. In December 1862 Moltke was asked for an opinion upon the military aspect of the quarrel with Denmark then becoming acute. He thought the difficulty would be to bring the war to an end, as the Danish army would if possible retire to the islands, where, as the

Danes had the command of the sea, it could not be attacked. He sketched a plan for turning the flank of the Danish army before the attack upon its position in front of Schleswig, and hoped that by this means its retreat might be intercepted. When the war began in February 1864, Moltke was not sent with the Prussian forces, but kept at Berlin. The plan was mismanaged in the execution, and the Danish army escaped to the fortresses of Düppel and Fredericia, each of which commanded a retreat across a strait on to an island. The allies were now checked; Düppel and Fredericia were besieged by them, Düppel taken by storm, and Fredericia abandoned by the Danes without assault; but the war showed no signs of ending, as the Danish army was safe in the islands of Alsen and Fünen. On the 30th of April Moltke was sent to be chief of the staff to the commander-in-chief of the allied forces, and, so soon as the armistice of May and June was over, persuaded Prince Frederick Charles to

FIELD-MARSHAL VON MOLTKE.
(From a photograph by Loescher and Petsch, Berlin.)

attempt to force the passage of the Sundewitt and attack the Danes in the island of Alsen. The landing was effected on the 29th of June, and the Danes then evacuated Alsen. Moltke next proposed a landing in Fünen, but it was unnecessary. The Danes no longer felt safe in their islands, and agreed to the German terms. Moltke's appearance on the scene had quickly transformed the aspect of the war, and his influence with the king had thus acquired a firm basis. Accordingly, when in 1866 the quarrel with Austria came to a head, Moltke's plans were adopted and he was almost invariably supported in their execution. A disciple rather of Clausewitz, whose theory of war was an effort to grasp its conditions, than of Jomini, who expounded a system of rules, Moltke regarded strategy as a practical art of adapting means to ends, and had developed the methods of Napoleon in accordance with the altered conditions. He had been the first to realize the great defensive power of modern firearms, and had inferred from it that an enveloping attack had become more formidable than the attempt to pierce an enemy's front. He had pondered the tactics of Napoleon

at Bautzen, when the emperor preferred to bring up Ney's corps, coming from a distance, against the flank of the allies, rather than to unite it with his own force before the battle; he had also drawn a moral from the combined action of the allies at Waterloo. At the same time he had worked out the conditions of the march and supply of an army. Only one army corps could be moved along one road in the same day; to put two or three corps on the same road meant that the rear corps could not be made use of in a battle at the front. Several corps stationed close together in a small area could not be fed for more than a day or two. Accordingly he inferred that the essence of strategy lay in arrangements for the separation of the corps for marching and their concentration in time for battle. In order to make a large army manageable, it must be broken up into separate armies or groups of corps, each group under a commander authorized to regulate its movements and action subject to the instructions of the commander-in-chief as regards the direction and purpose of its operations. In the strategy of 1866 the conspicuous points are: (1) The concentration of effort. There were two groups of enemies, the Austro-Saxon armies, 270,000; and the North and South German armies, 120,000. The Prussian forces were 64,000 short of the adverse total, but Moltke determined to be superior at the decisive point against the Austro-Saxons; he therefore told off 278,000 men for that portion of the struggle, and employed only 48,000 men in Germany proper. His brilliant direction enabled the 48,000 to capture the Hanoverian army in less than a fortnight, and then to attack and drive asunder the South German forces. (2) In dealing with Austro-Saxony the difficulty was to have the Prussian army first ready—no easy matter, as the king would not mobilize until after the Austrians. Moltke's railway knowledge helped him to save time. Five lines of railway led from the various Prussian provinces to a series of points on the southern frontier on the curved line Zeitz-Halle-Görlitz-Schweidnitz. By employing all these railways at once, Moltke had the several army corps moved simultaneously from their peace quarters to points on this curved line. When this first move was finished the corps then marched along the curve to collect into three groups, one near Torgau (Elbe army), another at the west end of Silesia (first army, Prince Frederick Charles), the third between Landshut and Waldenburg (second army, Crown Prince). The first army when formed marched eastwards towards Görlitz. The small Saxon army at Dresden now had the Elbe army in its front and the first army on its right flank, and as it was outnumbered by either of them, its position was untenable, and so soon as hostilities began fell back into Bohemia, where it was joined by an Austrian corps, with which it formed an advance guard far in front of the Austrian main army concentrated near Olmütz. The Elbe army advanced to Dresden, left a garrison there, and moved to the right of Prince Frederick Charles, under whose command it now came. (3) Moltke now had two armies about 100 miles apart. The problem was how to bring them together so as to catch the Austrian army between them like the French at Waterloo between Wellington and Blücher. If, as was thought likely, the Austrians moved upon Breslau, the first and Elbe armies could continue their eastward march to co-operate with the second. But on 15th June Moltke learned that on the 11th of June the Austrian army had been spread out over the country between Wildenschwerdt, Olmütz, and Brünn. He inferred that it could not be concentrated at Josefstadt in less than thirteen days. Accordingly he determined to bring his own two armies together by directing each of them to advance towards Gitschin. He foresaw that the march

of the Crown Prince would probably bring him into collision with a portion of the Austrian army; but the Crown Prince had 100,000 men, and it was not likely that the Austrians could have a stronger force than that within reach of him. The order to advance upon Gitschin was issued on the 22nd of June, and led to one of the greatest victories on record. The Austrians marched faster than Moltke expected, and might have opposed the Crown Prince with four or five corps; but Benedek's attention was centred on Prince Frederick Charles, and he interposed against the Crown Prince's advance four corps not under a common command, so that they were beaten in detail, as were also the Saxons and the Austrian corps with them, by Prince Frederick Charles. On the 1st of July Benedek collected his already shaken forces in a defensive position in front of Königgrätz. Moltke's two armies were now within a march of one another and of the enemy. On the 3rd of July they were brought into action, the first against the Austrian front and the second against the Austrian right flank. The Austrian army was completely defeated and the campaign decided, though an advance towards Vienna was needed to bring about the peace upon Prussia's terms. Moltke was not quite satisfied with the battle of Königgrätz. He had tried to have the Elbe army brought up to the Elbe above Königgrätz so as to prevent the Austrian retreat, but its general failed to accomplish this. He also tried to prevent the first army from pushing its attack, hoping in that way to keep the Austrians in their position until retreat should be cut off by the Crown Prince, but he could not restrain the impetuosity of Prince Frederick Charles and of the king. During the negotiations Bismarck, who dared not risk the active intervention of France, opposed the king's wish to annex Saxony and perhaps other territory beyond what was actually taken. Moltke would not have hesitated; he was confident of beating both French and Austrians if the French should intervene, and he submitted to Bismarck his plans in case of need for the opening moves against both French and Austrians.

After the peace, the Prussian Diet voted Moltke the sum of £30,000, with which he bought the estate of Creisau, near Schweidnitz, in Silesia. In 1867 was published *The Campaign of 1866 in Germany*, a history produced under Moltke's personal supervision, and remarkable for its combination of accuracy with reticence. On the 24th of December 1868 Moltke's wife died at Berlin. Her remains were buried in a small chapel erected by Moltke as a mausoleum in the park at Creisau.

In 1870 suddenly came the war with France. The probability of such a war had occupied Moltke's attention almost continuously since 1857, and a series of memoirs is preserved in which from time to time he worked out and recorded his ideas as to the best arrangement of the Prussian or German forces for the opening of the campaign. The arrangements for the transport of the army by railway were annually revised in order to suit the changes in his plans brought about by political conditions and by the growth of the army, as well as by the improvement of the Prussian system of railways. The great successes of 1866 had strengthened Moltke's position, so that when on the 15th of July 1870 the order for the mobilization of the Prussian and South German forces was issued, his plans were adopted without dispute, and five days later he was appointed "Chief of the general staff of the army at the headquarters of his Majesty the King" for the duration of the war. This gave Moltke the right to issue in the king's name, though of course not without his approval, orders which were equivalent to royal commands. Moltke's plan was to assemble the whole army to the south of Mainz, this being the one district in

which an army could best secure the defence of the whole frontier. If the French should disregard the neutrality of Belgium and Luxemburg, and advance on the line from Paris to Cologne or any other point on the Lower Rhine, the German army would be able to strike at their flank, while the Rhine itself, with the fortresses of Coblenz, Cologne, and Wesel, would be a serious obstacle in their front. If the French should attempt to invade South Germany, an advance of the Germans up either bank of the Rhine would threaten their communications. Moltke expected that the French would be compelled by the direction of their railways to collect the greater part of their army near Metz, and a smaller portion near Strasburg. The German forces were grouped into three armies: the first of 60,000 men, under Steinmetz, on the Moselle below Treves; the second of 131,000 men, under Prince Frederick Charles, round Homburg, with a reserve of 60,000 men behind it; the third under the Crown Prince, of 130,000 men, at Landau. Three army corps amounting to 100,000 men were not reckoned upon in the first instance, as it was desirable to keep a considerable force in north-eastern Germany, in case Austria should make common cause with France. If, as seemed probable, the French should take the initiative before the German armies were ready, and for that purpose should advance from Metz in the direction of Mainz, Moltke would merely put back a few miles nearer to Mainz the points of debarkation from the railway of the troops of the second army. This measure was actually adopted, though the anticipated French invasion did not take place. Moltke's plan of operations was that the three armies while advancing should make a right wheel, so that the first army on the right would reach the bank of the Moselle opposite Metz, while the second and third armies should push forward, the third army to defeat the French force near Strasburg, and the second to strike the Moselle near Pont-à-Mousson. If the French army should be found during this advance in front of the second army, it would be attacked in front by the second army and in flank by the first or the third or both. If it should be found on or north of the line from Saarburg to Lunéville, it could still be attacked from two sides by the second and third armies in co-operation. The intention of the great right wheel was to attack the principal French army in such a direction as to drive it north and cut its communications with Paris. The fortress of Metz was to be observed, and the main German forces, after defeating the chief French army, to march upon Paris. This plan was carried out in its broad outlines. The battle of Wörth was brought on prematurely, and therefore led, not to the capture of MacMahon's army, which was intended, but only to its total defeat and hasty retreat as far as Châlons. The battle of Spicheren was not intended by Moltke, who wished to keep Bazaine's army on the Saar till he could attack it with the second army in front and the first army on its left flank, while the third army was closing towards its rear. But these unintended or unexpected victories did not disconcert Moltke, who carried out his intended advance to Pont-à-Mousson, there crossed the Moselle with the first and second armies, then faced north and wheeled round, so that the effect of the battle of Gravelotte was to drive Bazaine into the fortress of Metz and cut him off from Paris. Nothing shows Moltke's insight and strength of purpose in a clearer light than his determination to attack on the 18th of August, when many strategists would have thought that, the strategical victory having been gained, a tactical victory was unnecessary. He has been blamed for the last local attack at Gravelotte, in which there was a fruitless heavy loss; but it is now known that this attack was ordered by the king, and

Moltke blamed himself for not having used his influence to prevent it. During the night following the battle Moltke made his next decision. He left one army to invest Bazaine and Metz, and set out with the two others to march towards Paris, the more southerly one leading, so that when MacMahon's army should be found the main blow might be delivered from the south and MacMahon driven to the north. On the 25th of August it was found that MacMahon was moving north-east for the relief of Bazaine. The moment Moltke was satisfied of the accuracy of his information, he ordered the German columns to turn their faces north instead of west. MacMahon's right wing was attacked at Beaumont while attempting to cross the Meuse, his advance necessarily abandoned, and his army with difficulty collected at Sedan. Here the two German armies were so brought up as completely to surround the French army, which on the 1st of September was attacked and compelled to raise the white flag. After the capitulation of Sedan, Moltke resumed the advance on Paris, which was surrounded and invested. From this time his strategy is remarkable for its judicious economy of force, for he was wise enough never to attempt more than was practicable with the means at his disposal. The surrender of Metz and of Paris was a question of time, and the problem was, while maintaining the investment, to be able to ward off the attacks of the new French armies levied for the purpose of raising the siege of Paris. Metz surrendered on the 27th of October, and on the 28th of January 1871 an armistice was concluded at Paris by which the garrison became virtually prisoners and the war was ended.

On the 29th of October 1870 Moltke was created Graf (count or earl), and on the 16th of June 1871, field-marshal. After the war he superintended the preparation of its history, which was published between 1874 and 1881 by the great general staff. In 1888 he resigned his post as chief of the staff. In 1867 Moltke was elected to the North German Diet, and in 1871 to the Reichstag. His speeches, dealing mostly with military questions, were regarded as models of conciseness and relevancy. He died suddenly on the 24th of April 1891, and after a magnificent funeral ceremony at Berlin his remains were laid beside those of his wife in the chapel which he had erected as her tomb at Creisau.

As a strategist Moltke cannot be estimated by comparison with Frederick or Napoleon, because he had not the authority either of a king or of a commander-in-chief. While it is doubtful whether he can be convicted of any strategical errors, it seems beyond doubt that he never had to face a situation which placed any strain on his powers, for in the campaigns of 1866 and 1870 his decisions seemed to be made without the slightest effort, and he was never at a loss.

He had a tall spare figure, and in his latter years his tanned features had received a set expression which was at once hard and grand. He was habitually taciturn and reserved, though a most accomplished linguist, so that it was said of him that he was "silent in seven languages." The stern school of his early life had given him a rare self-control, so that no indiscreet or unkind expression is known to have ever fallen from him. Long before his name was on the lips of the public he was known in the army and in the staff as the "man of gold," the ideal character whom every one admired and who had no enemies.

(Nine volumes appeared between 1892 and 1900.)—*Feldmarschall Moltke*. By MAX JÄHNS. 3 vols. Berlin, 1894-1900.—*Feldmarschall Graf Moltke: Ein militärisches Lebensbild*. By W. BIGGE, OBERST, &c. 2 vols. Munich, 1901.

Molton, South, municipal borough, and ancient market-town in the South Molton parliamentary division of Devonshire, England, 12 miles east-south-east of Barnstaple by rail, on the river Mole. There are a shirt and collar factory, and numerous corn mills, all worked by the river. The gasworks belong to the corporation. Population (1881), 3340; (1901), 2848, the area having been altered between 1891 and 1901.

Moluccas, groups of islands lying between Celebes on the west and New Guinea on the east, in the Malay Archipelago (*q.v.*), between 2° 43' N. and 8° 23' S. and 124° 22' and 135° E., with an area, inclusive of Dutch or Western New Guinea, of about 160,000 square miles. Since 1867, when the political unity, under a governor, was dissolved, the Moluccas are often named by the Dutch the "Great East" (*Groote Oost*). Politically they now belong to the residencies of Amboyna and Ternate. Most of the islands are mountainous, with still active volcanoes. As they lie near or under the equator, the monsoons blowing over them are less regular, and the rainfall, of large volume throughout the year, is dependent on the height and direction of the chains. The vegetation of the small and narrow islands, all encompassed by the sea, is very luxuriant, and the products, principally nutmegs, mace, and other spices, include also rice and sago. The original inhabitants, Alfuros, have become mixed with the traders and colonists of later times—the Makassars, Buginese, Javanese, and Europeans. See CELEBES, SERANG, TERNATE, TIDOR, TIMOR, NEW GUINEA (DUTCH).

Mombasa, a seaport town and the administrative capital of British East Africa (East African Protectorate), on the east side of a small island of the same name, close to the coast, in 4° S. It has two good harbours; one, Kilindini, is a naval depôt. Its total trade in 1901 amounted to £423,000, of which £348,600 were imports and £74,400 exports. These last consist principally of ivory, copra, hides, and rubber. Population, about 27,000. See EAST AFRICA, BRITISH.

Momein, the Burmese name of the Chinese city Teng Yueh-chow, a town in the south-west of the province of Yunnan, China. It was opened to foreign trade by the Burmese convention of 1897, but so far no advantage has been taken of the permission. It lies close to the Burmese frontier, and on the old trade route from Bhamo to Yunnan, but its importance as an outpost of the British empire is political rather than commercial. Near Momein and within its jurisdiction is the frontier town of Manwyne, where Mr A. R. Margary, a member of H.B.M. consular service, was assassinated in January 1875 (*vide* CHINA).

Mommsen, Theodor (1817—), German historian, was born on 30th November 1817, at Garding, in Schleswig, where his father was the pastor; he was the eldest of three brothers (the others being August and Tycho), who earned distinction in scholarship. After being educated in the gymnasium at Altona and the University of Kiel, he devoted himself to the study of Roman law and antiquities. In 1839 he published, with his brother Tycho and another friend, a short collection of poems of no great merit. In 1843 a grant from the Danish Government enabled him to undertake a journey to Italy, which was to be as decisive for his future career as was the Italian journey of Goethe or of Ranke. There he began the study of Roman inscriptions, in association with other Italian and German scholars, especially Borghesi, de Rossi, and Henzen. His first work was directed to the restoration of the old Italian dialects. It was a time when the necessity for compiling a complete

collection of all extant Roman inscriptions was becoming pressing. Mommsen's work attracted attention, and the French Government, which at one time proposed to undertake the task, asked for his co-operation. When they gave up the project it was taken up by the Berlin Academy, which had recently completed the collection of Greek inscriptions edited by Boeckh. They had already made a grant to Mommsen, and in 1844 Savigny proposed that he should be appointed to carry out the great work. The Academy, however, feared the expense, and there were rival claimants, especially Zumpt; many years accordingly passed before the plan was finally approved. Meanwhile Mommsen continued his work in Italy: he drew up a full memorandum explaining the principles on which a *Corpus Inscriptionum* should be compiled, and on which alone he could undertake the editorship; he insisted that it should be based on a fresh examination of every stone, and not a mere compilation from existing collections. As a specimen he collected the inscriptions of Sannium, and in 1852 published the inscriptions of the kingdom of Naples. These works caused him to be recognized as the first authority in this field of learning. In 1847, however, he was obliged to return to Germany: he first went to Schleswig, where during the Revolution he edited a paper in which he supported the claims of the Elbe Duchies; at the end of 1848 he was appointed professor of civil law at Leipzig. His work there was interrupted by his political opinions. During 1848, when the extreme party was in the ascendant, Mommsen supported the monarchy against the Republicans. With characteristic courage and independence, next year, when the Revolution had spent its force and Beust executed his *coup d'état*, he protested, with many of his colleagues, against this act, but was summoned before a disciplinary court, and, together with Haupt and Jahn, two of the other most distinguished scholars of that generation, to whom his *Roman History* was afterwards dedicated, he was dismissed from his professorship.

Like many other Germans, Mommsen found an asylum in Switzerland, and became professor at Zürich: he repaid the hospitality of the Republic by writing exhaustive monographs on Roman Switzerland. His spare time was occupied with the *Roman History*, undertaken at the suggestion of a publisher, whose daughter he married. The three volumes appeared between 1854 and 1856. His name at once became known throughout Europe. It was a new thing in Germany for a great scholar to write a book which men who were not scholars would read. The fruits of profoundest learning were given without display of erudition. With a true insight into the relative importance of things, he passed over with a few strong broad touches the antiquarian discussions on the origins of the city, on which previous historians had laboured so long; but in place of this he painted with astonishing vigour the great political struggle that accompanied the fall of the Republic. It was, above all, his new reading of old characters which demanded attention, if not always approval: Cicero, the favourite of men of letters, was for him "a journalist in the worst sense of the word"; Pompey, the hero of Plutarch and the Moralists, was brushed aside as a mere drill-sergeant; and the book culminated in the picture of Cæsar, who established absolute rule in the name of democracy, "the complete and perfect man." The work had more than a mere literary interest; it was one of the numerous influences which awoke in the rising generation the feeling that what Germany wanted was not theories and principles of government, but power and efficiency. But he always disclaimed the belief that in his panegyric of Cæsar he was thinking of and recommending the new Cæsarism of Napoleon III.

The three volumes ended with the dictatorship of Cæsar. The book has never been continued, for the volume on the *Roman Provinces under the Empire*, which appeared in 1884, though nominally the fourth volume of the history, is in reality a separate work. Mommsen was henceforward fully occupied with work of a more technical nature. In 1854 the definite offer was made to him by the Academy that he should be chief editor of a *Corpus Inscriptionum*, with full control. In order that he might carry on the work, he was appointed to a professorship at Berlin (for two years he had already been at Breslau), and for over forty years he was occupied in producing this great work. The first volume appeared in 1861, followed by sixteen others; and Mommsen lived to see his task completed so far as work of this kind ever can be complete. Five of the volumes he edited himself, and the whole was executed according to his instructions, under his immediate supervision and co-operation to a great extent, by scholars whom he had himself trained. It is the finest example of that association in learning which he made the text of one of his addresses to the Academy.

Enormous as was the labour, this task occupied only a small part of his extraordinary intellectual energy. During these forty years he found time to write two larger works, the *History of the Roman Coinage* and the *Römisches Staatsrecht*, a profound analysis of Roman constitutional law. His *Roman Provinces* already mentioned gives a singularly interesting picture of certain aspects of social life under the Empire. His smaller papers amount to many hundreds in number, and there is no department of Roman life and learning, from the earliest records of the Roman law to the time of Jornandes, which he has not illuminated. Nor did this exhaust his activity. He has himself realized the ideal of a scholar which was in his mind when he said, "Each one must specialize in one branch of learning, but not shut himself up in it. How miserable and small is the world in the eyes of the man who sees in it only Greek and Latin authors or mathematical problems!" As secretary to the Berlin Academy for over twenty years he took a leading part in their deliberations, and was their spokesman on great occasions. His interest in political problems of the present was as keen as in those of the past. He was one of the founders of the *Preussische Jahrbücher*, the most influential of German political periodicals. For many years he was a member of the Prussian Parliament. His political opinions were strong but ill-regulated. Intensely nationalist, he acquiesced in the annexation of his native land to Prussia, and in a public letter to the Italian nation in 1870 defended the German cause before the nation which had become to him a second fatherland; but he was of too independent a character ever to be quite at ease under Prussian government. Loving liberty, he hated its consequences; a democrat, he had and always expressed a profound contempt for the mob. Like many idealists, he was a severe critic of the faults of his own and other countries, and he added something to the increasing Chauvinism in Germany. He was one of the few men in high position who always refused to bow the knee to Bismarck. A member of the *Freisinnige* party, he was even brought to trial in 1880 because in an election address he had used the expression "Politik von Schwindel" of the Government. He defended himself, and was acquitted.

It was, however, above all, German scholarship which remained his first interest. There is probably no other instance in the history of scholarship in which one man has established so complete an ascendancy in a great department of learning. Equally great as antiquary, jurist, political and social historian, he lived to see the time when among students of Roman history he had

pupils, followers, critics, but no rivals. He combined the power of patient and minute investigation with a singular faculty for bold generalization and the capacity for tracing out the effects of thoughts and ideas on political and social life. Partly, perhaps, owing to a philosophical and legal training, he had not the gift of clear and simple narrative, and he is more successful in discussing the connexion between events than in describing the events themselves. Though his *History* ends with the fall of the Republic, his most enduring work has been that on the Empire; and if he has not written the history of the Empire, he has made it possible for others to do so.

The *History of Rome* (including the volumes on the Provinces) has been translated into English; there is a French edition of his work on *Roman Coinage*. Many of his pamphlets and articles have been collected under the title *Römische Forschungen*. Of his other works, the more important are the *Roman Chronology to the Time of Cæsar* (1858), a work written in conjunction with his brother August; his editions of the *Monumentum Ancyranum* and of the *Digest* in the *Corpus Juris Civilis*. A great part of his work is to be found in the German learned publications such as *Hermes*, *Rheinisches Museum*, &c. A full list of his works is given by Zaugemeister, *Mommsen als Schriftsteller* (1887).

Monaco, the smallest sovereign principality of Europe, on the Mediterranean, 9 miles east of Nice, and surrounded by the French Alpes Maritimes, with an area of about 3 square miles and a population of (1890) 13,304. It includes the towns of Monaco (3292), Condamine (6218), and Monte Carlo (3794). The principality at one time included Mentone and Roccabruna, now known as Roquebrune, which towns, however, were ceded to France in 1861 for a sum of four million francs. The ruler of the principality, Prince Albert, born 1848, succeeded his father, Prince Charles III., in 1889. He married in 1869 Lady Mary Douglas Hamilton, by whom in 1870 he had a son, Prince Louis: that marriage was, however, annulled in 1880, and subsequently Prince Albert married Alice, dowager-duchess of Richelieu.

The interest of the principality centres in the Casino of MONTE CARLO, which is visited by thousands of people from every part of the world; but the natural attractions of the place are sufficiently great, apart from its connexion with gambling. It is a common experience for travellers to Monte Carlo to leave England shrouded in snow, and in well under twenty-four hours to find themselves beneath a cloudless blue sky, in a climate which makes the shade welcome, surrounded by summer foliage and flowers. The journey, or at least the latter part of it, has also charms of its own. It is customary to leave Paris in the evening, the trains being provided with *wagon-lits* and *lit-salons*, which afford as comfortable sleeping accommodation as can be procured on the ill-laid Paris, Lyons and Mediterranean line. Marseilles is reached in the morning, and the first glimpse of the Mediterranean obtained, thence nearly to St Raphaël the line is mostly inland, but afterwards it runs by the sea, past singularly beautiful coast scenery. Numberless tiny bays indent the shore; into them the blue waters of the tideless sea ripple gently, or if there be any wind the waves break in snowy showers against the jagged rocks. From the left-hand window of the carriage endless acres of olive-trees covering the valleys at the foot of the hills are to be seen; the yellow flower of the mimosa brightens the picture, as do the orange-trees, the rich fruit of which peeps through the dark green leaves; palms, aloes, cacti, and other tropical plants are frequent. On some of the hill-tops are forts which suggest watchfulness and vigour in restraint. Cannes and Antibes are passed, Nice at length is reached, and passing through a number of tunnels,

Monte Carlo.

which make the glimpses of the shore all the brighter, the train runs through Monaco to Monte Carlo.

There appear to have been some gambling-tables here in the year 1856, but it was in 1861 that M. Blanc, seeing his tenancy at Homburg coming to an end with no hope of renewal, obtained a concession for fifty years from Charles III. This concession passed into the hands of a joint-stock company, which in 1898 obtained an extension to 1947, in return for a payment to the prince of £400,000 in 1899 and of £600,000 in 1913, together with an increase of the annual tribute of £50,000 to £70,000 in 1907, £80,000 in 1917, £90,000 in 1927, and £100,000 in 1937.

M. Blanc was a man who did nothing by halves. He set to work to build the Salons des Jeux, the famous—or infamous—Casino, and began to devise means to attract wealthy pleasure-seekers from all countries to the little principality. He erected the Hôtel de Paris, a notably fine structure in comparison with the hotels of the period; the best available chefs were employed, a dinner at least equal to that obtainable at the leading Paris restaurants was here to be had for a tenth of the amount it would there have cost; wines of the best vintages were to be procured at cost price or under; beautiful gardens were laid out and assiduously tended; attached to the Casino was a concert-room, where an admirable orchestra of carefully-selected musicians could be heard without payment by those who cared to stroll in and take a seat. The comfort and convenience of visitors were considered in every possible way, the shrewd administrator knowing that his outlay would come back to him with interest from the tables. Other hotels rapidly sprang up, handsomely served and appointed; sumptuous villas were built; in the Salons des Jeux tables were added, and now the twelve devoted to roulette and the four to trente-et-quarante are found insufficient, for at the busiest hours of the afternoon—play begins at mid-day, and continues till eleven o'clock in the evening—a crowd four or five deep prevents many who are anxious to tempt fortune from approaching near enough to stake. The pressure has been somewhat relieved latterly by the establishment upstairs of a *cercle privée*, where the games are continued till long past midnight under the same conditions as downstairs, except that visitors are here allowed to smoke, tobacco and the wearing of hats being interdicted in the lower room.

Admission to the salon is obtained by ticket. Turning to the left on entering the Casino, the would-be player finds a number of clerks seated in a small room. He presents his visiting card, and is furnished with a *carte d'admission*, making him free of the Cercle des Etrangers de Monaco for one day; but if he desires an extension it is afterwards readily obtainable. On the back of the *carte* it is stated that "Une tenue de ville convenable est indispensable pour obtenir l'entrée dans les salons," and the applicant is warned that "Cette carte ne peut être délivrée que sur la production de pièces d'identité sérieuses," as also that "Cette carte doit être présentée pour l'entrée dans les salons et peut être retirée." The holder's signature and that of *le commissaire spéciale* complete the business. Entering the rooms at any hour, play is sure to be found in progress. Early in the day not all the tables are occupied, though on the other hand many persons who have been keen to begin have waited in the capacious atrium for the opening of the doors, in order that they might rush to secure their favourite places. Liveried attendants stand about, furnished with ruled cards, on which some players like to keep records of the numbers which have turned up; and these servants will also supply large pins, for at trente-et-quarante it is a favourite custom to

score by means of pricks. At the newspaper kiosks in the gardens round the Casino, and at shops in the town, all sorts of brochures giving details of various systems of play can be procured, together with diagrams of the tables and all sorts of information about the methods in vogue.

Under the heads of ROULETTE and TRENTE-ET-QUARANTE these games are elsewhere described; it will suffice here to remark that by no system can success by any possibility be assured, for the simple reason that at both games, but much more especially at roulette, there is a steady percentage in favour of the bank which must inevitably tell in its favour in the long run.

There are thirty-seven numbers on the roulette board, including zero; the table pays only thirty-five times the player's stake on the winning number, so that practically from every coin won something is deducted. As a rule, however, players are not satisfied with one stake. The ways in which the *mise* can be placed are almost innumerable, and if players stake on different numbers and combinations, so much more does the bank secure. There are various systems which frequently bring profit for a time, though on the other hand they may be defeated at the first attempt, and subsequently day after day; but if the player were to stake blindfold he would have just as good a chance of winning as he can have by any method of calculation. Sometimes when *rouge, pair, or manque* has turned up several times players will stake on them again because of the "run"; sometimes, on the contrary, they will stake on the opposites, *noir, impair, and passe*, because it seems the turn of those to come up. In truth there are no turns, and one way is just as sensible or as foolish as the other. In these days of multi-millionaires it might seem to the uninitiated that force of money, if some system of gradual increase were adopted, would in time defeat the bank; but here the bank protects itself by limiting the stakes to various maximums, beyond which it is not permissible to wager. On this subject an instructive little anecdote may perhaps be related. One morning on the terrace by the Casino overlooking the sea a visitor was in conversation with an old croupier, and made mention of a system that had been recommended. The old man shook his head. "There are more than 150 of us croupiers employed in that building, sir," he said; "we sit there and watch the game hour after hour, week after week, year after year. Some of us are not fools. Do you not think that if any successful system existed, one of us would have found it out before now?" At trente-et-quarante many players are accustomed to follow "the run of the table," as it is termed—that is to say, to wager on the colour which last won; but there is of course no foundation for the idea that runs of colour are more likely to happen than intermittences. Very often nearly all the coins and banknotes will be on one side, either on red or black, and very often therefore the bank makes a rich haul with little or nothing to pay. The morality of gambling is not here in question; the folly of it is surely evident. The only point is whether the gambler derives from playing what he considers sufficient amusement to recompense him for the money he loses.

The natural beauties of Monte Carlo, and the warm climates comparatively near to places where more rigorous temperatures are the rule, might well tempt visitors to the principality. A very special temptation, however, is the luxury which prevails, apart from those beauties which nature has provided. The whole district for miles round has benefited by the influx of wealth, and travellers on the roads beyond Bordighera cannot fail to be struck by the comparative squalor of the surroundings in contrast

Casino.**

with the charming villas, superb gardens, well-provided shops, and perfect roads which distinguish Monte Carlo and the neighbourhood. Concerts are no longer free in the Casino. The room has been turned into a theatre, where operatic performances, supported by the best singers, are given during the season. A Salon des Beaux Arts has been built, and pictures of more or less merit are always on exhibition. Here, too, theatrical representations sometimes take place in the afternoons. Indoor entertainments are not likely to receive much patronage when the days are fine; but those who have

*Environns
of Monte
Carlo.*

visited Monte Carlo on only a few occasions, and have been fortunate in their weather, would be surprised to find how bleak and wet the sunny south can sometimes be. Deep snow on the racecourse at Nice once actually led to the abandonment of the steeplechases that annually take place there and are a feature of the season, and more than once they have been interfered with by frost; though whenever this happens the residents, jealous for the reputation of their town, will declare that such a thing was never known before in the memory of the oldest inhabitant. Rainy weather causes grave dismay at Monte Carlo, and with regard to climate it may be noted that genial as is the sun during the day, the evenings are often treacherous and chilly. A favourite pastime is a drive to Nice, which enables one to enjoy the beautiful coast scenery in more leisurely fashion than when viewing it during the more rapid railway journey. Off Beaulieu, and in the picturesque harbour of Villefranche, yachts are often anchored, and in the latter not seldom French men-of-war. Long since the district appealed to Lord Salisbury, whose villa on the hillside above Beaulieu became one of the landmarks of the district. On the east of Monte Carlo lies Mentone, some five miles away along a road which winds round the bays, and within a long drive farther on, past Ventimiglia and Bordighera, are the frontiers of Italy, with the picturesque old town of San Remo accessible for well-horsed carriages or motors. Travellers who propose to make the journey thitherwards by rail from Monte Carlo will do well to remember the great difference between French and Italian time, for French time is adopted in the principality, though in some respects the prince maintains the integrity of his own little land. Thus Monte Carlo issues its own postage stamps; and one coin, a handsome five-louis gold piece, bears the prince's effigy, and may perhaps be described as only current in his abbreviated dominion, for even at Nice not a few of the shopkeepers look at it with curiosity and doubt.

A particularly agreeable walk from Monte Carlo is down the hill by the Condamine, and round the rock of Monaco, upon which the prince's palace, part of which dates from 1572, and the administrative buildings, are erected. The rock was fortified by Louis XIV., and some quaint old cannon, with piles of round iron cannonballs, are supposed to guard the fortress. A portion of the wealth which flows into the little country has been devoted to the building of a beautiful church here. The path winds down, high up above the Mediterranean, through well-kept gardens, until turning the corner Monte Carlo is seen across the bay, with the Casino prominent, and near to it the little semicircular patch of green upon which pigeon-shooting is practised during several weeks of the season. Looking to the right Corsica may usually be discerned. The bay has been described as a favourite anchorage for English and other yachts, but this statement must be accepted with reservations, as when certain winds prevail an ugly sea is frequently raised, rendering the harbour dangerous. Plans for the construction of a breakwater have been mooted. Beyond and behind Monte

Carlo rises the mountain, with its olive-clad slopes and carefully cultivated terraces, at the top of which, on the old Cornice road, is situated the village of La Turbie, and this may now be reached by a cog-wheeled mountain railway. Trains run at frequent intervals during the day.

(A. E. T. W.)

Monaghan, an inland county of Ireland, province of Ulster. The area of the administrative county in 1900 was 318,806 acres, of which 113,311 were tillage, 169,112 pasture, 450 fallow, 4291 plantation, 5646 turf bog, 1184 marsh, 1514 barren mountain, and 23,298 water, roads, fences, &c. The new administrative county under the Local Government (Ireland) Act, 1898, is identical with the old judicial county.

The population in 1881 was 102,748; in 1891, 86,206; and in 1901, 74,505, of whom 37,034 were males and 37,471 females, divided as follows among the different religions: Roman Catholics, 54,708; Protestant Episcopalians 9532; Presbyterians, 9515; Methodists, 407; and other denominations, 343. The decrease of population between 1881 and 1891 was 16·1 per cent., and between 1891 and 1901, 13·6, the largest decrease in both decades of any county in Ireland. The average number of persons to an acre in 1891 was ·27, and of the total population, 81,236 persons inhabited the rural districts, being an average of 183 persons to each square mile under crops and pasture.

The following table gives the degree of education in 1891:—

	Males.	Females.	Total.	Percentage.			
				R. C.	Pr. Ep.	Presb.	Meth.
Read and write	27,011	25,586	52,597	60·9	79·4	86·4	91·7
Read only	4,955	7,107	12,062	17·2	12·1	8·7	4·6
Illiterate	6,927	7,092	14,019	21·9	8·5	4·9	3·7

The percentage of illiterates among Roman Catholics in 1881 was 28·1. In 1891 there were 7 superior schools with 178 pupils (Roman Catholics, 111, and Protestants, 67), and 188 primary schools with 12,236 pupils (Roman Catholics, 8633, and Protestants, 3603). The number of pupils on the rolls of the national schools on 31st December 1900 was 12,460, of whom 8959 were Roman Catholics and 3501 Protestants. The following table gives the number of births, deaths, and marriages in the years specified:—

Year.	Births.	Deaths.	Marriages.
1881	2379	1779	391
1891	1598	1486	349
1900	1410	1567	334

In 1900 the birth-rate per thousand was 18·9, and the death-rate 21·0; the rate of illegitimacy was 2·5 per cent. of the total births. The total number of emigrants who left the county between 1st May 1851 and 31st December 1900 was 73,825, of whom 38,404 were males and 35,421 females. The chief towns in the county, with their populations in 1901, are: Monaghan, 2938; Clones, 2065; Carrickmacross, 1880.

Administration.—The county is divided into two parliamentary divisions, North and South, the number of registered electors in 1901 being respectively 6863 and 6765. The rateable value in 1900 was £274,904. By the Local Government (Ireland) Act, 1898, the fiscal and administrative duties of the grand jury were transferred to a county council, urban and rural district councils were established, and under that Act the county now comprises 4 urban and 7 rural sanitary districts.

Agriculture.—The following tables show the acreage under

“L'ÉGLISE DE VÉTHEUIL,” By CLAUDE MONET.
(In the Luxembourg Gallery.)

crops, including meadow and clover, and the amount of live stock in 1881, 1891, 1895, and 1900 :—

Year.	Wheat.	Oats.	Barley, Rye, Beans, &c.	Potatoes.	Turnips.	Other Green Crops.	Flax.	Meadow and Clover.	Total.
1881	1049	55,964	2298	21,328	7877	1865	15,088	32,154	133,223
1891	985	46,046	1236	21,960	7422	2270	6,913	88,260	125,042
1895	446	45,504	712	21,427	7849	2112	9,214	42,215	129,479
1900	506	42,481	895	19,065	7085	2142	2,085	39,112	113,321

In 1900 the total value of the cereal and other crops was estimated at £632,197. The number of acres under pasture in 1881 was 140,532; in 1891, 158,840, and in 1900, 169,112.

Year.	Horses and Mules.	Asses.	Cattle.	Sheep.	Pigs.	Goats.	Poultry.
1881	11,071	3571	70,292	11,313	19,965	12,305	440,508
1891	12,721	4210	86,174	21,378	30,225	14,339	517,518
1895	14,139	4570	85,294	16,220	34,795	13,086	561,411
1900	12,466	4568	90,387	17,753	34,001	13,128	700,152

The number of milch cows in 1891 was 30,940, and in 1900, 31,151. The total value of cattle, sheep, and pigs for 1900 was £1,203,382. In 1900 the number of holdings not exceeding 1 acre was 855; between 1 and 5, 1888; between 5 and 15, 7366; between 15 and 30, 4941; between 30 and 50, 1560; between 50 and 100, 530; between 100 and 200, 114; between 200 and 500, 22, and above 500, 4—total, 17,280. The number of loans issued (the number of loans being the same as the number of tenants) under the Land Purchase Acts 1885, 1891, and 1896, up to 31st March 1901, was 2642, amounting to £613,016. The number of loans for agricultural improvements sanctioned under sect. 31 of the Land Act, 1881, between 1882 and 1901 was 113, and the amount issued, £6317. The total amount issued on loan for all classes of works under the Land Improvement Acts, from the commencement of operations in 1847 to 31st March 1901, was £46,750. (W. H. Po.)

Monastir, the second city of Macedonia, and the capital of the vilayet of Monastir in European Turkey, situated in a valley watered by the Kara Su, an affluent of the Vardar, and on the Salonica-Monastir railway, 400 miles west of Constantinople. The chief exports are cereals, flour, hides, woollen stuffs, and bones. The total value of the exports in 1899 was £71,000 and of the imports £299,500. The city is the headquarters of the third army corps, and possesses nine mosques, a military hospital, a school of art and science, &c. Population, 60,000.

Monchique, a town of Portugal, in the district of Faro, 40 miles north-west from Faro, on the Serra de Monchique. Three miles south of the town there are hot sulphur springs, with baths and a sanatorium. Wheat, millet, rye, beans, vegetables, wine, olive oil, and chestnuts are the chief products, and there is a woollen factory. Population, about 7000.

Moncton, a city and port of entry in Westmoreland county, New Brunswick, the centre of the Intercolonial railway. It has a good harbour, good municipal buildings and schools, nine churches, three banks, and two daily newspapers; an iron foundry, cotton, woollen, and flour mills, and other industries. In 1901 the value of the exports was \$591,523; imports, \$495,688. Population (1891), 8762; (1901), 9026.

Mondovi, a town and episcopal see of the province of Cuneo, Piedmont, Italy, 14 miles by rail east of Cuneo. It has a school of the industrial arts and handicrafts, manufactures majolica and paper, and raises cocoons. Population (1881), 10,302; (1899), 9000. About 2 miles to the east the sanctuary of Vico, a church designed by Ascanio Vittozzi in 1590, and crowned by a famous dome (1730-48), has been declared a national monument. In the square before it is a monument (1891) to Charles Emmanuel I. of Savoy.

Monet, Claude (1840—), French painter, was born in Paris 14th November 1840. His youth was passed at Hâvre, where his father had settled in 1845. Until he was fifteen years old he led a somewhat irregular life, learning little at school, and spending all his time in decorating his books with drawings and caricatures which gave him notoriety in Hâvre. At the same time he became acquainted with Boudin, a clever sea-painter, under whose guidance he learned to love and to understand nature. At the age of twenty he became a soldier, and spent two years of his military time with the regiment of the Chasseurs d'Afrique in the desert. Falling ill with fever, he was sent home, and entered the studio of Gleyre. This classical painter tried in vain to keep him to conventional art and away from truth and nature, and Monet left his studio, where he had become acquainted with two other "impressionistic" painters, Sisley and Renoir. At that time he also knew Manet (*q.v.*) and in 1869 he joined the group of Cézanne, Degas, Duranty, Sisley, and became a *plein air* (open-air) painter. During the war of 1870 he withdrew to England, and on his return was introduced by Daubigny to a dealer, M. Durand-Ruel, in whose galleries almost all his works have been exhibited. In 1872 he exhibited views of Argenteuil, near Paris; in 1874 a series entitled "Cathedrals," showing the Cathedral of Rouen under different lights. He afterwards painted views of Vétheuil (1875, see Plate), Pourville and cliffs of Étretat (1881), of Bordighera (1886), of the Creuse (1889), Le Meules (1891), and some further views of cathedrals (1894). In December 1900 he exhibited some pictures called "Le Bassin des Nymphéas," and was engaged at the beginning of 1901 in painting views of London. Several of Monet's paintings, bequeathed by M. Caillebotte, are in the Luxembourg Museum, Paris. (See also IMPRESSIONISM.)

See GUSTAVE GEFFROY. *La Vie Artistique (passim)*.—J. VAN DYKE (Ed.). *Modern French Masters*. London, 1896.

Monforte, a township of Spain, in the province of Lugo, on the railway from Palencia to Corunna. The population in 1897 was 12,664. In the old part of the town there are a tower, belonging to the Counts of Leon; a hospital, in an old convent; the church of San Vicente, a handsome Renaissance structure; and a palace of the Counts of Leon. The new part of the town contains a fine Jesuit college. Monforte has several convents and an ancient synagogue. The local industries are the manufactures of linen and soap, saw-milling, and live stock rearing.

Monghyr, a town and district of British India, in the Bhagalpur division of Bengal. The town is on the right bank of the Ganges, and has a railway station, with steam ferry to the railway on the opposite bank of the river. Population (1881), 55,372; (1891), 57,077; (1901), 35,883, a decrease of 37·1 per cent. between 1891 and 1901. Cheap firearms, swords, and other iron articles are still manufactured. The high school had 302 pupils in 1896-97. There are two printing-presses, and Mahommedan, Hindu, and bar associations.

The district of MONGHYR has an area of 3921 square miles; population (1881), 1,969,950; (1891), 2,036,021; (1901), 2,064,077, showing an increase of 3 per cent. between 1881 and 1891, and of 1·4 per cent. between 1891 and 1901; average density, 526 persons per square mile. Classified according to religion, Hindus in 1891 numbered 1,839,159; Mahommedans, 191,770; Christians, 1324, of whom 592 were Europeans; aborigines, 3768. The land revenue and rates in 1897-98 were Rs.10,36,442; number of police, 487; number of boys at school (1896-97), 28,308, being 19 per cent. of the male population of school-going age; registered death-rate (1897), 32·65 per thousand. The principal industry is indigo. There are eleven factories, employing 12,000 persons, with an out-turn of 3000 maunds valued at Rs.3,61,000. The southern portion of the district is well provided with railways. At

Lakhisarai junction the arc and chord lines of the East Indian railway divide, and here also starts the branch to Gaya. At Jamalpur, which is the junction for Monghyr, are the engineering workshops of the company.

Möng Nai (called by the Burmese and on most old maps *Monè*), one of the largest and most important of the states in the eastern subdivision of the southern Shan States of Burma. The state of Kēng Tawng (Burmese *Kyaing Taung*) is a dependency of Möng Nai. It lies approximately between 20° 10' and 21° N. and between 97° 30' and 98° 45' E., and occupies an area of 2716 square miles. The Salween river bounds it on the east. The main state and the sub-state of Kēng Tawng consist of two plains with a ridge between them. There is much flat paddy bottom, but a considerable portion consists of gently undulating plainland. In 1891 the population was estimated at 18,600 persons, and with Kēng Tawng 21,170; in 1897, 23,673. In the central plain rice is the only crop. Outside this considerable quantities of sugar are produced. Tobacco of a quality highly esteemed by the Shans is grown in the Nawng Wawp circle at an altitude of 3100 feet above sea level; gram, *thanatpet* (a leaf used for cigar wrappers), and garden crops are the chief produce otherwise. In the outlying districts quantities of coarse native paper are manufactured from the bark of a species of mulberry, and much is exported to other parts of the Shan States. This is almost the only thing the state has to export, and the bullock caravans, which are fairly numerous, are chiefly engaged in a carrying trade with the produce of other states, bringing cotton and silk piece goods, salt, kerosene oil, and the like up from Mandalay or Toungoo.

Under King Thibaw the Möng Nai state was reduced to a terrible state of desolation, from which it is only slowly recovering. Möng Nai, the capital, was the seat of the chief Burmese official in the Shan States, and the remains of pagodas and monasteries point to past wealth. There were not fifty houses when the Sawbwa made his submission to the British Government in 1887. The number had grown to 800 in 1898, when a fire destroyed the whole town, but the bamboo and thatch houses were rebuilt within a few months. There is an American Baptist Mission school and dispensary in the town. The political officer in charge of the eastern division now has his headquarters at Bampôn, a village ten miles west of Möng Nai town, with a post of 75 rifles. Möng Nai town stands on the western edge of a valley about 12 miles long with an average width of 3 miles, 5 at the town, where there are two lakes. The annual tribute paid by the state is Rs.13,000. The Sawbwa has visited Rangoon, Gaya in India, and Ceylon on pious pilgrimages.

(J. G. Sc.)

Mongolia, a vast territory belonging to the Chinese Empire, the administrative limits of which cannot be determined with precision. On the north it is bounded by the frontier of Russia, beginning at Mount Kalas or Kanas (49° 5' N. and 87° 40' E.) in the Altai, and running to the south-east corner of Transbaikalia in the vicinity of Dalai-nor, thus having on the north the Siberian provinces of Tomsk, Yeniseisk, Irkutsk, and Transbaikalia. In the east the boundary line which separates Mongolia from Manchuria runs past Dalai-nor and Lake Buir, crossing the Great Khingan in 47° 30' N. towards Tsitsihar in Manchuria; then, crossing the Nonni river, it strikes the Sungari at Khulan-chen, where it turns westwards up this river, reaching the Lao-ho or Shara-muren river in 123° 30' E. From China proper on the south Mongolia is separated by a line running in a south-westward direction up the Shara-muren and across the Mongolian plateau to the bending of the Hoang-ho or Yellow river in about 40° N. and 110° 30' E. Thence the boundary describes a sinuous line, following the Great Wall, and thus includes the Ordos (Ho-tao) and Alashañ (Si-tao), and reaches its most southern point in 36° 40' N. and 104° 20' E. Thence it turns north-west, following the Great Wall for over 300 miles; it then crosses the plateau so as to separate Mongolia

from the Chinese province of Hañ-su-sin-tsian (which includes the Nan-shan highlands and eastern Turkestan) and from Dzungaria, reaching the Chinese or Ektag Altai in 46° 30' N. and 92° 50' E. From that point the boundary coincides with the main water-parting of the Altai mountains till it reaches Mount Kalas.

Geographically, Mongolia may thus be said to occupy both terraces of the great plateau of east Asia, which stretches in the south of Siberia, between the Sailughem range of the Great Altai and the Great Khingan—with the exception of the Dzungarian depression. From Manchuria and China it is separated by the border ridge of the plateau—the Great Khingan, while in the south-west it runs up to the foot of the high northern border-ridges of the Tibetan plateau—an artificial frontier separating it from east Turkestan and Dzungaria. Broadly speaking, Mongolia may be divided naturally into three parts: (1) north-western Mongolia, which occupies the high terrace of the plateau; (2) the Gobi, in its wide sense, covering the lower terrace of the plateau, together with a slightly more elevated and better-watered zone along the western slope of the Great Khingan and its south-western continuation; and (3) south-eastern Mongolia, on the eastern slope of the Khingan.

I. NORTH-WESTERN MONGOLIA.

This was formerly represented as a region intersected by lofty mountain chains. It appears, however, from Russian explorations during the last third of the 19th century that it has all the characteristics of an elevated plateau, of a rhomboid shape (like Bohemia), bounded by four mountain ranges; namely, the Russian Altai on the N.W., the western Sayans on the N.E., the Kentei range on the S.E., and the Ektag Altai on the S.W. The border-ridge character of the west Sayans (Ergik-targak-taiga) is well established, and the same orographic character is confirmed by recent explorers with regard to the Sailughem range of the Altai. The only point still remaining undecided is whether the valleys of the Bom-kemchik (a tributary of the Yenisei) and its left-hand tributaries do not belong geographically to the Altai region. At any rate, throughout the whole of north-west Mongolia, which covers an area of nearly 370,000 square miles, the altitude nowhere falls below 2370 feet (Ubsa-nor); and the area round this lake which has less than 3000 feet of altitude covers only 6600 square miles. The remainder of this extensive territory ranges at altitudes of from 3000 to 4500 feet, even in the bottoms of the river valleys and in the lower plains; while the ridges which constitute the water-partings rise a couple of thousand feet above the general level of the plateau. Along the south-western border of this division of Mongolia a gigantic border-ridge, the Ektag (or Mongolian) Altai, runs in an east-south-eastern direction from the Russian Altai to 99° E. long., and is probably continued even farther by the Artsa-bogdo, the Saikhat, and other ranges as far as the northern loop of the Yellow river. The passes across the Ektag Altai lie at altitudes of 10,000 feet in the north-west and 9250 feet in 93° 20' E.; farther east they become much lower. But while its southern foot stands in the Dzungarian trench, *i.e.*, at altitudes of 1550 feet only near Lake Ulungur, and at 3000 feet in 94° E., its north-eastern foot rests on the high plateau, *i.e.*, at 4260 feet at Kobdo, 5410 at Oshku, 4070 at Orok-nor on the route from Kiakhtah to Su-chow, and so on. Thus the Ektag Altai is a true border-range—that is, a lofty and steep escarpment facing the Dzungarian depression, with a gentle and relatively short slope towards the plateau.

In the same way the Kentei (or Gentei) mountains, as they are called, to the south of Urga, and the Yablonovoi Khrebet of Transbaikalia, separate the higher terrace of north-west Mongolia (drained by the tributaries of the Selenga) from the lower terrace of the Gobi, which is drained by the upper tributaries of the Onon and the Kerulen, both belonging to the basin of the Amur. It is also very probable that the Tannu-ola mountains to the north-east of Ubsa-nor, and the Khangai mountains between Ulyasutai and the upper Orkhon, both running west-north-west to east-south-east, border another slightly higher terrace of the same great plateau of north-west Mongolia, upon which Lake Kosogol lies, at an altitude of 5320 feet. On this vast upper terrace even the bottoms of the river valleys are at altitudes of 4200 to 5500 feet, with one single exception—the narrow gorge of the Khua (Khi)-khem, or upper Yenisei; while the highest pass across the Tannu-ola mountains is 7090 feet, though the others are much lower. The conception of north-west Mongolia as a region filled with mountain ranges radiating from the Altai must thus be abandoned. It is a massive swelling of the earth's crust, representing the northern

counterpart of the plateau of Tibet. This massive swelling is cut into, between the Ektag Altai and the eastern Tian-shan, by the relative depression of Tarbagatai and Dzungaria, 1500 to 3000 feet in altitude; while to the south of the eastern Tian-shan comes the Tarim depression, from 2200 to 3000 feet high, and occupying an area of about 88,000 square miles. Neither of these "depressions," however, penetrates beyond 94° E., and (see Skassi's map) on the route from Kiakhta to Su-chow, in 100° E., there is only one single place (42° N.) in which the altitude drops as low as 3300 feet; everywhere else it varies between 4000 and 5000 feet.

Lakes and Rivers.—North-western Mongolia is well watered, and has in its western part a group of lakes which possess no outlet to the ocean, being in reality the rapidly desiccating remains of what were formerly much larger basins. The chief of them is Ubsanor (2370 feet), which receives the large river Tes. It lies in the middle of a large plain, and has to the west of it a smaller but much higher lake, Urga-nor, besides several smaller ones. Farther south on the same wide plain lie the sister lakes Kirghiz-nor and Airyk-nor, which receive another large river, the Dzap'hyn, and the Kungui. Many small lakes are scattered over the plain to the east of them. A third group of lakes occurs in the neighbourhood of Kobdo. The Kobdo river, which rises in the Dain-gol (7060 feet) in the Ektag Altai, winds in great curves across the plateau, and enters Lake Kara-usu (3840 feet), which also receives the Buyantu, an outflow from Lake Kobdo, and is connected by a small river with another large lake, Durga-nor, situated a score of miles to the east. There are also many smaller lakes fed by the glaciers of the Sailughem (Ashit-nor, 4650 feet, and Uryu-nor), and others scattered through the Ektag Altai. The largest lake of this region is, however, Kosogol (Khubsu-gul), which lies at an altitude of 5320 feet, close to the Russian frontier, at the foot of the snowclad Munku-sardykh. Besides the rivers just mentioned, there are others belonging to the basin of the Yenisei (Khua-or Khi-khem, Beikhem, and Bom-kemchik); while yet others belong to the Selenga, a river formed by the junction of the Eder with the Telghir. The Selenga receives the Tola, at the head of which, the Orkhon, remarkable inscriptions were discovered in the end of the 19th century, and cleverly deciphered by Professor V. Thomsen of Copenhagen.¹ The rivers which flow down the outer slopes of the border-ridges become lost in the Gobi shortly after entering it.

A very large portion of north-west Mongolia constitutes a high plain, 3000 to 4200 feet in altitude, which penetrates from the south-east in a north-western direction between the Ektag Altai and the Khangai mountains. It has a true Mongolian character, *i.e.*, it is covered with gravel, and presents the appearance of a dry prairie devoid of forests. This same character is also exhibited by the bottoms of the broad valleys, while the more elevated and hilly portions of the territory, especially on their northern slopes, are covered with larch, cedar, pine, and deciduous trees belonging to the Siberian flora; where the forests fail they are marshy or assume the character of Alpine meadows—*e.g.*, in the Khangai, the Tannu-ola, and on the slopes of the border-ridges. The whole of this region is covered with excellent pasture. The forests decrease as one travels southwards. For instance, while both slopes of the Sayans are covered with forests, the Tannu-ola and the Khangai mountains have woods on their northern faces only, and the Ektag Altai is quite devoid of woods, even on its northern slope.

Climate.—Owing to its high altitude, north-western Mongolia is very cold, and the severity of the winter is intensified by the prevalence of cold but dry north-western winds. The north-east wind brings more moisture. In summer the warm winds come from the south and south-east, but having first to cross the Gobi, they are dried before they reach north-western Mongolia. The yearly amount of rain at Urga (altitude 4350 feet, at the northern foot of the Kentei mountains is only 9½ inches, and the average temperatures are: year 27° F., January -18°, July 64°; a minimum of -35° F. has been observed. The climate of Ulasutai (5400 feet) may be taken as typical, its average temperatures being: year 31.6°, January -12°, July 66°.

The *geology* is still very imperfectly known. The plateau is built up of granites, gneisses, and crystalline schists of Archæan and probably Primary age. Coal is known to exist to the south-east of Kobdo, in the Tannu-ola, and in the basin of the Yenisei, but its age is unknown (fresh-water Jurassic?). Graphite and some silver ores have also been found.

The *fauna* is a mixture of the Siberian and the Daurian—the latter penetrating up the valleys of the Selenga basin.

The *population* of north-west Mongolia is mixed, and contains, besides Mongols and Kalnuks, also Turkish tribes; namely, Kirghiz, on the slopes of the Ektag Altai; Uryankhs, about Kosogol as well as on the middle course of the Kobdo river (Kokchulutuns); and Kotons, who dwell on the lands of the Durbet (Dorbod) Kalnuks about Ubsa-nor. In the vicinity of this there are also Mussulman immigrants from east Turkestan; and Chinese are found in all the

towns. Cattle-breeding is the chief occupation, agriculture being carried on, and then to no great extent, only about Ubsa-nor, occasionally beside the Selenga, and in the southern parts of the Ektag Altai. Hunting is a favourite occupation, and furs (especially of marmots) and stags' horns (*sayans*) are exported in considerable quantities. The transport of goods to and from China is also a large source of income. The chief towns of this division of Mongolia are Urga, Ulasutai, Kobdo, and Ulan-kom.

II. THE GOBI.

Geographically speaking, the Gobi comprises the lower terrace of the great plateau of east Asia, bounded on the N.W. by the slopes of the Kentei mountains, and on the E. and S.E. by the Great Khingan mountains, from which it is, however, separated by a borderland, about 100 miles wide, belonging to the foot-hills of the latter range. Its southern limits cannot yet be definitely determined, as the Gobi cannot very well be separated from Alashan. In the west, as appears from the journeys of the brothers Grum-Grzimallo, its natural limits are the hilly tracts of the Bei-shan, which occupy the space between the 94th and 100th degrees of longitude (route from Hami or Khami to Su-chow), rising to altitudes of 4000 to 7500 feet. In view of this the Hashuñ Gobi, or Ilhuma, with the Kum-tagh Sands (40° N. and 92° E.), might be advantageously considered as part of the Tarim region. The 95th meridian may be taken as separating the Gobi from Dzungaria. The Mongolian word *Gobi*, as well as the Chinese *Sha-mo*, means a desert, stony or sandy, devoid of water and pasturage; but the resulting current conception of the Gobi as a sand desert is absolutely incorrect. Nowhere does it contain such sand deserts as are found in the Transcaspien territory, but everywhere presents the characteristics of an open, flat, or undulating plain, covered with a hard coating of gravel, from which the wind has swept the lighter and minuter particles of mud or sand, and from beneath which the hills and mountains protrude littered with fragments of rock, much as islands emerge from the sea. As to the name of Han-hai, proposed by Richthofen, it has the disadvantage of presupposing that all the Gobi-like portions of the plateau have been covered by a Central Asian Mediterranean, which is supposed to have levelled the mountains. However, the very origin of the plateau-forms on our globe, as well as the origin of the gravel with which the Gobi is covered, is very far from being known. Everywhere throughout the Gobi a formation of red and brown conglomerates, sandstones, and clays is very common; this most travellers, following Richthofen's hypothesis, have described as deposits of a Tertiary "Han-hai sea." But after traversing some 20,000 miles of the Mongolian plateau, the professional geologists Bogdanovitch and Obrucheff, who have both devoted considerable attention to the red "Gobi or Han-hai deposits," have discovered but one fossil (Obrucheff), namely, the enamel of the teeth of a rhinoceros—a testimony which points to a fresh-water origin of these deposits rather than to a hypothetical Han-hai sea, which consequently remains a mere speculation. On the other hand, Jurassic coal-bearing deposits are known to exist in several places in the Gobi, but all of them, as is proved by their well-explored fossil flora and insects, were deposited in separate fresh-water basins. Since Bogdanovitch has shown that the fossils which Stoliczka picked up in the Sanju Pass at its issue into Kashgaria are Upper Devonian (see KUEN-LUN) and not Triassic, the total absence of marine formations of the Secondary and Tertiary ages on the Mongolian plateau—and during 1885-1900 it was crossed and explored in all directions by a number of scientific explorers—is the more striking from the fact that deposits of these two epochs have been found everywhere on the outer slopes of the plateau—on the Amur, the Sungari, in the Peking plain, and even in the Kalgan gorge, leading down the plateau towards Peking, as well as on the south-eastern slopes of the In-shan border ridge of the plateau.

The Kentei range which limits the Gobi in the north-west, from the Transbaikalian frontier (109° 30' E.) to the point where it appears to join the Ektag Altai (in about 45° N. and 102° E.), is apparently an escarpment, or border-ridge, of the higher terrace of the plateau occupied by north-west Mongolia, which is fringed (at least to the south-west of Urga) by a second parallel ridge.¹ Farther to the south-west comes the Bei-shan swelling, about 150 miles wide, the border of which runs, broadly speaking, in a north-western direction from the Nan-shan highlands to the extremity of the eastern Tian Shan. It consists of high dry plains, rapidly rising from 2300 feet in the south-east of Hami to 4000 feet in 42° N., and to 5000 and 6000 feet farther south-

¹ The sources of the Onghin-gol, penetrating into the upper terrace, may mask the connexion. It remains also an open question whether traces of the Kentei escarpment may not be found in a south-west direction as far as 42° N., where they possibly join the Bei-shan, in which case they would separate the higher plains of Jasaktu-khan (4650 to 5920 feet) from the lower plains (3300 to 4000 feet) to the south-east of it.

¹ See V. Thomsen, *Inscriptions de l'Orkhon* (Helsingfors, 1900).

east, and is intersected by a series of parallel ridges, running west-south-west to east-north-east, and reaching about 1000 feet above the plains (7000 to 7420 feet in the maximum). The Hashuñ Gobi to the west of this swelling is still but little known. This, however, is known, that along its northern border a relatively narrow depression (2000 to 3000 feet) extends west and east at the southern foot of the eastern Tian Shan from Lake Bagrach-kul (42° N. and 87° E.) to 94° 30' E.; and another similar depression fringes it on the south, along the northern foot of the Altyn-tagh, from Lob-nor (2600 feet) to the small lake of Halachi (3500 feet), situated west-north-west of Su-chow. In the south-west the Gobi may be considered as limited by the Nan-shan highlands (see KUEN-LUN)—that is to say, by the Great Wall between Su-chow and Lan-chow on the Yellow river, or rather by the Sin-tang, the Veitsi-shang, and the Lu-huang-lin mountains. In reality, however, the Alashañ and the Ordos represent a slightly higher terrace of the Mongolian plateau. In the east the natural limits of the Gobi are the Great Khingan border-ridge, which runs from the Amur at Kumara to Kalgan near Peking, and is further continued by the In-shan mountains and the mountains which are pierced by the Yellow river in the south of Kia (38° 10' N. and 110° 20' E.). The Khingan, which is well known from 50° N. to the In-shan mountains, appears throughout this length, not as a single escarpment, but as a series of two or three parallel ridges, thus constituting a zone 80 to 100 miles wide, by which the Mongolian plateau drops south-eastwards to the deeper-lying plains (see KHINGAN). On the north-western slope of this border-ridge there is a zone, about 100 miles wide, which does not possess the exact characteristic features of the Gobi, but the features of an undulating high tableland, ridged with flat hills and low ranges, well wooded, well watered, and in places marshy. The Gobi proper is thus the deeper part of the trough extending over the lower terrace of the Mongolian plateau for over 1000 miles from south-west to north-east, with a width of from 450 to 550 or 600 miles in its south-western portion. The plateau itself is built up of granites, gneisses, and a variety of crystalline schists and slates, with limestones on its periphery, the youngest of which belong to the Carboniferous formation. Considerable layers of basalt and other volcanic formations occur in the border-ridges. As regards the causes which have produced the abrasion of the surface of the plateau, they are no better known in the case of the Gobi than they are in the case of all other plateaus of the world. Wind and frost are certainly powerful agents in the destruction of denuded rocks, and their force must not be undervalued. Anyway, it is indisputable that the wind has been active in destroying the softer "red Gobi deposits," and in sweeping the finer particles of mud and sand clean off the superficial gravels. Viewed from the Peking lowlands, clouds of dust are seen to envelop the slopes of the Great Khingan, and aerial agencies have unquestionably been at work in the deposition of the thick loess deposits which line the foot of the plateau and fill the valleys of Turkestan. But water must also have played a part in the laying down of these deposits, for usually they contain strata of pebbles in their lower parts. How far an ice-sheet, similar to that of Greenland, which covered the whole of the plateaus of Asia, may have contributed to the levelling of the mountains, is a question for future investigation to decide. The surface of the Gobi lies at altitudes of 2700 to 3000 feet, slightly increasing towards the Khingan mountains. The lowest elevation hitherto determined on this plateau is 2766 feet (907 metres, not 607 metres, as suggested by Obrucheff). But its surface is by no means level: it is diversified by ranges of hills, from 300 to 1000 feet above the general level of the plateau, and occasionally more (Khan-ula, 6400 feet). Perfectly flat plains are of limited extent; as are also sandy plains—the surface being undulating as a rule and intersected by small ravines and protruding rocky areas. Even the western Gobi, especially in its northern parts, as appears from the Kozloff expedition, is covered with numbers of parallel low ranges, which are pretty well watered and have an interesting fauna.

Rivers.—In the central parts of the Gobi there are no rivers. They only flow on its outer margin. Such are the Onon, a tributary of the Shilka; the Kerulen, which rises in the Kentei mountains and flows north-east into Dolon-nor or Khulun, from which it only occasionally overflows into the Arguñ; the Khalagol, a tributary of Buir-nor, connected by the Urgan with the former lake, on the north-east frontier of Mongolia; a number of small rivers, which flow from the Khingan mountains but dry up as soon as they reach the Gobi; the Hoang-ho or Yellow river, which describes a great loop round the Ordos; several rivers which flow from the Nan-shan but end in small lakes shortly after they enter the Gobi (*e.g.*, Shao-hai and lakes Sobok and Sobu); and the Onghin-gol, which rises in the Kentei mountains. In the interior of the Gobi, water is only obtainable from wells.

The climate of the Gobi is characterized by a great dryness of the air and rapid changes of temperature all the year round and even within twenty-four hours. Dr Woekoff has ascertained that the Gobi lies within the influence of the south-eastern monsoons.

In the winter the prevailing winds blow from the interior of the Asiatic continent towards the ocean, and are very dry, while in summer they blow in the opposite direction, and bring rain. At Si-van-tse the annual rainfall is 18 inches, and the absence of moisture is such that only 1 per cent. of saturation is observed. The cold in winter is truly Siberian—27° Fahr. has been observed in November in South Mongolia, while in the Alashañ the average daily temperature in July is truly Indian, *i.e.*, 99° Fahr., and temperatures of even 150° and 167° Fahr. in the shade have been observed. The average temperature at Si-van-tse is: year, 37°; January, 2°; July, 67°; maximum, 93°; minimum, -53°.

Flora and Fauna.—The vegetation is extremely poor; the *deseru*, the steppe acacia (*Caragana*), and *Festucas* are the commonest plants, together with a number of *Salsolaceæ* (*Nitraria*, *Ephedra*) and poplars along the rivers. It is only upon approaching the slopes of the mountains which encircle the region that other vegetation—*e.g.*, wild peaches, elm-trees, and so on—begins to appear. A little agriculture is carried on in the southern districts of the Gobi. The fauna has been well studied by Prjevalsky, and while it is generally similar to that of the Tian-shan region and Siberia, it has its own peculiar forms.

The Ordos or *Ho-tao*, in southern Mongolia, forms a sufficiently distinct region to be treated by itself. It is enclosed on the north by the great loop of the Hoang-ho, and in the south it is bounded by the mountains of Lu-huang-lin or the escarpment of the plateau towards the south. The Ordos is a gently sloping tableland, rising from 3300 feet in the north and in the vicinity of the Yellow river to 4400 in the middle, and reaching 5200 feet in the Lu-huang-lin. It is to a great extent covered with sand, especially in the north and west, and with wide depressions (*chaidam* or *tsaidam* in Mongolian), the basins of desiccated lakes; many smaller lakes are scattered over its surface. Minor tributaries of the Hoang-ho drain it in the east. The Arbus or Arbis mountains, and the Khantagheri, about 3000 feet above the surface of the plateau, appear on the right bank of the Hoang-ho, stretching in a north-north-east direction as a continuation of the Alashañ range. Several caravan routes intersect the Ordos, the principal one being that from Gui-hua-chen or Kuku-khoto, *viâ* Djungar, to Borobolghysun—the chief town of the province. There are also several towns in the eastern part of the province, on or near the Hoang-ho, namely, Fu-gu, Shan-mu, Yui-lin, and Kia, as well as in the south—Huai-shang, Tsin-kiang, Din-kiang, and Lin-chow.

The Alashañ range, to the west of the upper Hoang-ho, separates the Ordos from the Alashañ. It runs south-south-west to north-north-east for about 160 miles, with a width of about 16 miles, and lifts its crest 5000 to 7000 feet above the surrounding plateau (which is itself 3400 to 4800 feet high), and reaches 10,000 and 11,600 feet in the only two passes which cross it. This range does not reach the limit of perpetual snow, but is extremely stony and wild. The Alashañ is another vast territory of southern Mongolia; its northern frontier corresponds, broadly speaking, with 42° N., and its southern frontier lies on the Nan-shan highlands, while on the west it has the Bei-shan and on the east the Ordos. It also is a plateau covered by a network of hills, its lowest parts, in the lower valley of the Edzin-gol, being at altitudes of 4000 to 3500 feet (3290 in Sobok-nor), while the remainder of the region has an altitude of 4000 to 5000 feet, with ridges running up to another thousand feet. Its chief river is the Edzin-gol, which flows to the north-west along the foot of the Nan-shan, receiving several tributaries on the way. In 100° E. it turns towards the north, and finally dwindles away in the small lakes Soffok and Sobu. Two other rivers emerge from the Nan-shan, but are lost before they reach the Chukhun-shan hills.

Several towns of some importance, of which Liang-chow, Hang-chow, and Su-chow are the chief, have grown up along the foot of the Nan-shan, amidst a series of well-irrigated and well-cultivated oases, separated from each other by tracts of sand.

III. SOUTH-EASTERN MONGOLIA.

This is the part of Mongolia which lies on the eastern slope of the Great Khingan mountains, entering like a wedge between the lower course of the Nonni river and the middle Sungari. Chiefly owing to the dryness of climate, its physical characteristics are similar to those of Mongolia proper, except that the altitude of the plains is much lower. This portion of Mongolia is also much better watered, namely, by the Khatsyr, the Lao-ho, and the Shara-muren, all flowing from the Khingan mountains eastwards, and the last making the frontier between Mongolia and the Chinese province of Chihli.

Population.—The population of the whole of Mongolia is estimated at about 5,000,000. It consists of Mongols—Eastern Mongols and Kalmuks in the west—various Turkish tribes, Chinese, and Tungus. The Mongols proper, with the exception of those who inhabit north-west Mongolia, may be divided into northern and southern

(more properly north-western and south-eastern) Mongols. The former, belonging to the Khalkhas, occupy the Gobi and the regions of the Kentei mountains and Khingan mountains, while the second, divided into numerous minor branches, roam over south-eastern and southern Mongolia. The principal occupation of the Mongols is cattle-breeding, and Russian writers estimate that on an average each *yurta*, or family, has about 50 sheep, 25 horses, 15 horned cattle, and 10 camels. The transport of goods is their next most important occupation. It is calculated that 100,000 camels are used for the transport of tea only from Kalgan to Siberia, and that no less than 1,200,000 camels and 300,000 ox-carts are employed in the internal caravan trade. Agriculture is only carried on sporadically, chiefly in the south, where the Mongols have been taught by the Chinese. Various domestic industries are also carried on. The trade is chiefly concentrated at Urga, Ulasutai, and Kobdo, in north-west Mongolia; Kalgan, Kuku-khoto, Kuku-erghi, Dolon-nur, and Biru-khoto, in southern and south-eastern Mongolia; and at Kerulen in the north-east. There is a very considerable trade between Mongolia and China, estimated at £900,000 a year for Urga alone. Some 25,000 horses, 10,000 horned cattle, and 250,000 sheep, as well as 330,000 hides and £30,000 worth of furs, are exported annually from eastern Mongolia; and about 70,000 horses, 30,000 camels, 1,500,000 to 2,000,000 sheep, and £40,000 worth of furs from western Mongolia. Salt, timber, sarsaparilla, stags' horns, rhubarb (drug), mushrooms, &c., must be added; while tea, cottons (Chinese, European, and American), crockery-ware, cutlery, flour, tobacco, paper, &c., are imported from China. The imports from Russia increase every year, but are still a long way behind those from China, hardly reaching £200,000 yearly in value.

Administration.—Before the Manchurian conquest the Mongols were governed by their own feudal princes, who regarded themselves as being descended from seven different ancestors, all, however, of the same kin. Each group of principalities constituted a separate *aimak*, and each principality a separate *hoshun*. Under Manchu rule the *aimaks* became converted into the same number of military corps, each composed of so many *hoshuns* as military units. Each of these again was divided into *sumuns* or squadrons, each containing 150 families. In case a *hoshun* contained more than 6 *sumuns*, every 6 of the latter were organized into a regiment—*tsalan*. Four Manchu *tsian-tsuns*, or governor-generals, acted as chiefs of the troops, and the prince of each *aimak*, nominated from Peking, was considered as the lieutenant or assistant of his respective Manchu chief. The *hoshuns* were subject to their own princes, each of whom had a military adviser, generally a Manchu. Their internal or tribal affairs were in the hands of the princes, those which concerned a whole *aimak* being settled at gatherings of the princes under the eldest of them, named *khan*. This organization was maintained by the Manchu rulers, the *khan* being elected from among the princes, and the latter having each an adviser, *tsulakchi*, nominated from Peking.

Mongolia is now divided into 27 *aimaks*, which are bound to furnish 1325 squadrons, of 198,750 armed men, one-third of whom must carry rifles; but as a matter of fact the Mongols are not provided with arms for even one-tenth of that number (Pozdnéeff, in *Russian Encyclopaedical Dictionary*).

Authorities.—Of modern works the following are the most important:—PREJEVALSKY. *Mongolia and the Land of the Tanguts*, 1875; and his *Third and Fourth Journey*, 1883 and 1888.—POTANIN. *Sketches of North-West Mongolia*, 1881–83; *The Tangut-Tibet Border of China and Central Mongolia*, 1893 sq.—PYEVTSOFF. *Sketch of a Journey to Mongolia, &c.* Omsk, 1883.—Prof. POZDNÉEFF. *Towns of North Mongolia*, 1880; *Mongolia*

and the *Mongols*, 1896 and 1899; and the article "Mongolia" in *Russian Encycl. Dictionary*, xix., 1896.—G. and M. GRUM GRZMAILLO. *Description of a Journey to Western China*, 1898–99.—PYEVTSOFF, BOGDANOVITCH, ROBOROVSKY, and KOZLOFF. *The Tibet Expeditions*, 1886–1902.—V. OBRUCHEFF. *Central Asia, Northern China, and the Nan-shan*, 1900–1901.—MATUSOVSKIY. *Geogr. Descr. of Chinese Empire*, 1888.—BATORSKIY. *Essay of a Military and Statistic Sketch*, 1890.—WOYEIKOFF. *Climates of the Earth*, 1884. (All Russian.)—R. PUMPELLY. *Geol. Researches*, Washington, 1866.—NEY ELIAS, in *Journal R.G.S.*, 1873.—RICHTHOFEN. *China*, 1877.—J. GILMOUR. *Among the Mongols*, 1883.—ROCKHILL. *Journey through Mongolia and Thibet*, 1894.—F. E. YOUNGHUSBAND. *The Heart of a Continent*, 1896.

(P. A. K.)

Möng Pai (called *Mobyè* by the Burmese), the most south-westerly of the British Shan States of Burma. It has an approximate area of 1000 square miles. The general character of the country is hilly, rising westwards in a gentle slope from the chief stream, the Nam P'ilu or Balu. This is navigable for native boats throughout the year to the point where it sinks underground in Karen-ni. The chief cultivation is rice, with about two acres of dry or hill rice to one of wet bottom. The hill fields are left fallow for ten years after two years' cultivation. Population estimated in 1898 at 16,772, of whom 2520 were Shans, 2048 Taungthus, 617 Taungyos and Inthas (from the Nyaungwe Lake), and the remainder various tribes of Karens, of whom the Padaungs (7792) were the most numerous. The chief, the Sawbwa Hkun Yôn, held charge through the reigns of four Burmese kings, and submitted early in 1887 on the first arrival of British troops. He abdicated in favour of his son in 1890. The state pays Rs.2000 tribute.

Möng Pan (the Burmese *Maingpan*), a state in the eastern division of the Southern Shan States, lying approximately between 19° 45' and 20° 25' N. and between 98° and 99° E., with an area of 2299 square miles. The main state lies, except for a few insignificant circles, entirely west of the Salween, but beyond that river are the four sub-feudatory states of Möng Tôn, Möng Hang, Möng Kyawt, and Möng Hta. The only considerable area of flat land is round the capital, which lies in a large and fertile plain, marking roughly the centre of the state. From this plain rise on all sides low hills covered with scrub jungle, sloping up to ranges of about 5000 feet on nearly every side. Rice is the only crop, irrigated where possible; elsewhere dry cultivation prevails. The state has valuable teak forests on both sides of the Salween, which cover a considerable but undetermined area. The general altitude of the valleys is about 2000 feet. The state pays an annual tribute of Rs.2000. The capital is small, and has only about 200 houses. The chief is of Sawbwa rank. Population (1891), 3099; of the trans-Salween sub-states, 4000; (1898), about 9000.

Monier-Williams, Sir Monier (1819–1899), Sanskrit scholar, born at Bombay on 12th November 1819, was a son of Colonel Monier-Williams, surveyor-general, Bombay presidency. He matriculated at Oxford in 1837, but left the University on receiving in 1839 a nomination for the East India Company's civil service, and was completing his course of training at Haileybury when the entreaties of his mother, who had lost a son in India, prevailed upon him to relinquish his nomination and return to Oxford. He there devoted himself to the study of Sanskrit, and gained the Boden scholarship in 1843. After taking his degree he was appointed professor of Sanskrit, Persian, and Hindustani at Haileybury, where he remained until the abolition of the college upon the transfer of the government of India from the Company to the Crown. He taught Oriental languages at Cheltenham for ten years, and in 1860 was elected Boden professor of Sanskrit at Oxford

after a severe contest with Professor Max Müller (*q.v.*), which attracted great public interest and severe criticism, the motive of the non-resident voters whose suffrages turned the scale being notoriously not so much to put Monier-Williams in as to keep Max Müller out. Although, however, far inferior to his rival in versatility and literary talent, Monier-Williams was no way inferior in the special field of Sanskrit, and did himself and his professorship much honour by a succession of excellent works, among which may especially be named his Sanskrit-English and English-Sanskrit Dictionaries; his *Indian Wisdom*, an anthology from Sanskrit literature; and his translation of *Sakuntala*. In his later years he was especially attracted by the subject of the native religions of India, and wrote popular works on Brahmanism, Buddhism, and Hinduism. His principal undertaking, however, was the foundation of the Indian Institute at Oxford, which owes its existence entirely to him. He brought the project before the University in May 1875, and in that year and the following, and again in 1883, visited India to solicit the moral and financial support of the native princes and other leading men. Lord Brassey came to his aid with a donation of £9,000, and in November 1880 the Institute was adopted by the University, but the purchase of a site and the erection of a building were left to the professor. Upwards of £30,000 was eventually collected; the Prince of Wales, in memory of his visit to India, laid the foundation stone in May 1883; and the edifice, erected in three instalments, was finally completed in 1896. Ere this, failing health had compelled Monier-Williams to withdraw from the active duties of his professorship, which were discharged by the deputy-professor, Dr Macdonell, who afterwards succeeded him. He continued, nevertheless, to work upon Sanskrit philology until his death at Cannes on 11th April 1899. He had been made K.C.I.E. in 1889, when he adopted his Christian name of Monier as an additional surname. (R. G.)

Monkhouse, William Cosmo (1840-1901), English poet and critic, was born in London on 18th March 1840. His father, Cyril John Monkhouse, was a solicitor; his mother's maiden name was Delafosse. He was educated at St Paul's School, quitting it at seventeen to enter the Board of Trade as a junior supplementary clerk, from which grade he rose eventually to be the assistant-secretary to the finance department of the office. In 1870-71 he visited South America in connexion with the hospital accommodation for seamen at Valparaiso and other ports; and he served on different departmental committees, notably that of 1894-96 on the Mercantile Marine Fund. He was twice married: first to Laura, daughter of James Keymer of Dartford; and secondly, to Lenora Eliza, daughter of Commander Blount, R.N. He died in London, 20th July 1901, and was buried in Finchley Cemetery. Cosmo Monkhouse was one of those who have not only a vocation, but an avocation. His first bias was to poetry, and in 1865 he issued *A Dream of Idleness and other Poems*, a collection strongly coloured by his admiration for Wordsworth and Tennyson. It was marked by exceptional maturity, and scarcely received the recognition it deserved. Owing perhaps to this circumstance, it was not till 1890 that he put forth *Corn and Poppies*, a collection which contains at least one memorable effort in the well-known "Dead March." Five years later appeared a limited edition of the striking ballad *The Christ upon the Hill*, illustrated with etchings by Mr William Strang. After his death his poetical output was completed by *Parasites the Eluder and other Poems* (including *The Christ upon the Hill*). In 1868 Monkhouse essayed a novel, *A Question of Honour*. Then, after precluding with a *A Life*

of *Turner* in the "Great Artists Series" (1879), he devoted himself almost exclusively to art criticism. Besides many contributions to the *Academy*, the *Saturday Review*, the *Magazine of Art*, and other periodicals, he published volumes on *The Italian Pre-Raphaelites* (1887), *The Earlier English Water-Colour Painters* (1890 and 1897), *In the National Gallery* (1895), and *British Contemporary Artists* (1899). He also edited the *Life and Works of Joseph Wright* (1885), and his sister-in-law Mrs. Heaton's *Concise History of Painting* (1888). He prefaced many of the publications of the Burlington Fine Arts Club, of which he was a member, and he was a contributor to the *Dictionary of National Biography* from the beginning. Monkhouse also wrote an excellent *Memoir of Leigh Hunt* in the "Great Writers Series" (1887), and for civil service purposes compiled, in 1877, a little manual of *precis* writing. As an art critic Monkhouse's judgments were highly valued; and he had the rare gift of differing without offending, while he invariably secured respect for his honesty and ability. As a poet, his ambition was so wide and his devotion to the art so thorough, that it is difficult not to regret the slender bulk of his legacy to posterity. Some of the best of his pieces are to be found in Mr Miles's *Poets and Poetry of the Century*. (A. D.)

Monkswell, Robert Porrett Collier, 1st BARON, English judge (1817-1886), was born at Plymouth, 21st June 1817, and was the son of a prominent merchant of Quaker extraction. He was educated at Oxford, was called to the bar in 1843, and went the western circuit. He obtained a high reputation by his successful defence of Brazilian pirates in 1845: they were, indeed, convicted at the assizes, but Collier ultimately procured their escape upon a point of law which the judge had refused to reserve. He was elected member of Parliament for Plymouth in the Liberal interest in 1852, and in 1859 was appointed counsel to the Admiralty and judge-advocate to the Fleet. In this capacity he gave in 1862 an opinion in favour of detaining the Confederate rams building in the Merséy, which would have saved his country much money and much credit if it had been acted upon. In 1863 he became Solicitor-General, and in 1868 Attorney-General, and in 1869 successfully passed a Bankruptcy Bill. In 1871 he was appointed by Mr Gladstone one of four new judges upon the judicial committee of Privy Council, although it was expressly provided by the Act creating these offices that none of them should be filled by a law officer of the Crown. This prohibition was evaded by making Collier a judge of Common Pleas, and transferring him after a few days to the Privy Council. It is singular that neither Mr Gladstone, Lord Hatherley, nor Lord Selborne should have seen anything reprehensible in this arrangement, which was unanimously condemned by public opinion, and gave the Gladstone Cabinet a serious blow. Collier's qualifications were undoubted, but that was not the question. He officiated, nevertheless, with distinction until his death on 3rd November 1886, and was raised to the peerage as Baron Monkswell in 1885. He was a man of many accomplishments, and especially distinguished as an amateur painter, frequently exhibiting landscapes at the Royal Academy and elsewhere. In his younger days he had been noted as a clever caricaturist. He was succeeded in the peerage by his eldest son, Robert (b. 1845), who, after taking a first class in law at Cambridge, went to the bar, and became (1871) conveyancing counsel to the Treasury, and (1885-86) an official examiner of the High Court. As a Gladstonian Liberal he unsuccessfully sought a seat in the House of Commons, but for 1892-94 was a lord-in-waiting, and in 1895 Under Secretary of State for War in Lord Rosebery's

Government. Besides serving on parliamentary committees on the sweating system, the London hospitals, and the law of copyhold, he took a leading part in attempting to pass the Bills (1891, 1897) for amending the Copyright Acts.

(R. G.)

Monmouth, a maritime county of England, on the Welsh border, bounded on the E. by Gloucester, on the N.E. and N. by Hereford, on the N.W. by Brecknock, on the W. by Glamorgan, and on the S. by the estuary of the Severn.

Area and Population.—The area of the ancient county is 341,688 acres, or 534 square miles, with a population in 1881 of 211,172, in 1891 of 252,416, and in 1901 of 292,327, the number of persons per square mile being 547, and of acres to a person 1.16. The area of the administrative county, as given in the census returns of 1891, was (including the county borough of Newport) 324,701 acres, with a population of 253,054; but since 1891 certain changes have been made in the area, and in 1901 the population was 230,800. In 1894 this county received a small addition from Hereford, and in 1895 the contributory place of Roath in the rural district of Llandaff and Dinas Powis was transferred from Monmouth to the county borough of Cardiff in Glamorganshire, while the area which, prior to the passing of the Local Government Act of 1894, constituted the part of the parish of Rumney in the county borough of Cardiff, was transferred to Monmouth. The area of the registration county is 394,424 acres, with a population in 1891 of 275,242 (of which 206,368 were urban and 68,874 rural), and in 1901 of 316,875. Within the registration area the increase of population between 1881 and 1891 was 7.47 per cent., between 1881 and 1891 the increase was no less than 40,938, and between 1891 and 1901 it was 41,263, or 14.1 per cent. The population in 1901 numbered 316,875. The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Males.	Females.
1880	1076	7,900	4520	170	166
1890	2466	9,245	5433	136	163
1898	2085	10,299	4984	181	172

The number of marriages in 1899 was 2504; of births, 9924; and of deaths, 5872.

The following table gives the marriage-, birth-, and death-rates per thousand of the population, with the percentage of illegitimate births, for a series of years:—

	1870-79.	1880.	1880-89.	1890.	1888-97.	1898.
Marriage-rate	16.5	14.3	15.6	18.1	16.0	13.5
Birth-rate	38.1	33.8	34.5	34.0	34.6	33.4
Death-rate	22.1	19.3	19.8	20.0	19.0	16.2
Percentage of illegitimacy	4.3	4.3	4.1	3.2	3.3	3.4

The birth-rate is above the average, but the percentage of illegitimate births is small. In 1891 there were in the county 944 natives of Scotland, 3807 natives of Ireland, and 1159 foreigners.

Constitution and Government.—The county is divided into three parliamentary divisions, and it also includes the Monmouth district of parliamentary boroughs, consisting of Monmouth, Newport, and Usk. The administrative county contains three municipal boroughs: Abergavenny (7795), Monmouth (5095), and Newport, also a county borough (67,290). The following are urban districts: Abercarn (12,607), Abersychan (17,768), Abertillery (21,955), Bedwelty (9919), Blaenavon (10,869), Caerleon (1367), Chepstow (3067), Ebbw Vale (20,993), Upper Llanfrechfa (2979), Llantarnam (5287), Nantyglo and Blaina (13,491), Panteg (7482), Pontypool (6126), Rhymney (7914), Risca (9661), Tredegar (18,574), and Usk (1476). Monmouthshire is in the Oxford circuit, and assizes are held at Monmouth. The boroughs of Monmouth and Newport have commissions of the peace, but no separate court of quarter sessions. The ancient county—which is partly in the diocese of Llandaff and partly in that of Hereford—contains 120 ecclesiastical parishes and districts, and parts of others.

Education.—There is a board school for the blind at Newport. On 31st August 1899 there were in the county (including Newport) 200 elementary schools, of which 105 were board and 95 voluntary schools, the latter including 74 National Church of England schools, 1 Wesleyan, 13 Roman Catholic, and 7 "British and other." The average attendance at voluntary schools was 12,643, and at board schools 32,104. The total school board receipts for the year ended 29th September 1899 were over £140,127. The income under the Agricultural Rates Act was over £1411.

Agriculture.—Only about two-thirds of the total area of the county is under cultivation, and over three-fourths of this is in permanent pasture. There are also about 35,000 acres in hill pasture, 4000 under orchards, and 32,000 under woods. Wheat and oats are the principal corn crops, and turnips the principal green crop. Since 1880 the acreage under corn crops has diminished by considerably more than a third, and that under wheat by about a half. The following table gives the larger main divisions of the cultivated area at intervals from 1885:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	243,832	28,721	11,713	19,561	180,438	3348
1890	245,643	26,429	11,264	15,684	189,572	2616
1895	242,942	21,455	9,943	15,215	194,415	1715
1900	242,525	21,373	9,129	14,368	196,545	1008

The following table gives the numbers of the principal live stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1885	11,881	50,554	18,572	184,955	17,126
1890	11,999	46,893	18,609	200,311	17,590
1895	13,946	45,542	17,763	201,274	18,877
1900	13,209	49,799	18,008	227,142	16,426

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 16,945, as compared with 16,799 in 1896. Non-textile factories employed 15,200, of whom 8040 were employed in the founding and conversion, extraction and finishing of metals, and 3157 in the manufacture of machines; and there is some manufacture of paper. Of the 1704 employed in workshops, 1114 were employed in clothing industries. The prosperity of the county depends chiefly on its minerals. The total number of persons employed in mines and quarries in 1899 was 33,233. The same year 169,135 tons of clay were raised, much of it valuable fireclay, 79,323 tons of limestone, and 51,036 of sandstone. Some iron is obtained from the coal mines, but coal is by far the more important mineral, and on this account much iron is imported for smelting and other purposes. There are large smelting furnaces at Newport, Cwmbran, Ebbw Vale, Blaina, and Tredegar. The pig iron made in 1885 amounted to 438,092 tons, in 1890 to 399,538 tons, and in 1899 to 350,764 tons. The following table gives the tonnage and value of the principal minerals for 1890 and 1899:—

Year.	Fireclay.		Coal.		Iron Ore.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	97,745	£17,105	1,536,574	£437,070	17,435	£10,026
1899	79,481	19,870	10,103,067	6,061,840	12,794	6,397

Monmouth, a municipal and contributory parliamentary borough (forming, with Newport and Usk, the Monmouth district of boroughs, returning one member) of Monmouthshire, England, 18 miles south of Hereford, at the confluence of the Wye and the Monnow, on the Great Western railway. The Rolls Hall was presented to the town in 1888. Population (1881), 6111; (1891), 5470; (1901), 5095.

Monmouth, a city of Illinois, U.S.A., capital of Warren county, at the intersection of the Chicago, Burlington, and Quincy and the Iowa Central railways, in the western part of the state, at an altitude of 774 feet. It is in a coal region and has some manufactures, largely of agricultural implements. It is the seat of Monmouth College. Population (1890), 5936; (1900), 7460, of whom 594 were foreign-born and 321 were negroes.

Monmouth, a village in Monmouth county, New Jersey, U.S.A., about 28 miles east of Trenton. It was the scene of a sharp battle in the war of the American Revolution, in which neither side was victorious. In June 1778 the British troops, under Sir Henry Clinton, evacuated Philadelphia in order to concentrate all available forces in New York. General Washington followed in pursuit, and a battle took place at Monmouth Court House, about two miles from Freehold, the county seat. The losses of the two armies were about equal, approximately 400 on each side.

Monongahela, a city of Washington county, Pennsylvania, U.S.A., on the west bank of the Monongahela river and on the Pennsylvania and the Pittsburg and Lake Erie railways, in the south-western part of the state, at an altitude of 753 feet. It is in a mining region, producing coal, petroleum, and natural gas, with which its industries are connected. Population (1890), 4096; (1900), 5173, of whom 711 were foreign-born and 345 were negroes.

Monopoli, a seaport town and archiepiscopal see of the province of Bari, Apulia, Italy, on the Adriatic coast, 26 miles south-east of Bari by rail. Its trade has declined owing to the successful rivalry of Tarentum (Taranto), Brindisi, and Bari; but it still exports olive oil, wine, flour, fruits, soap, and lime, and imports a little timber, cattle, coal, and cotton. The port is cleared by some 180 vessels of about 100,000 tons annually. Population (1881), 13,154; (1899), 12,000.

Monroe, a city of Louisiana, U.S.A., capital of Ouachita parish, on the east bank of the Ouachita river, on the Queen and Crescent and the St Louis, Iron Mountain, and Southern railways, in the northern part of the state, at an altitude of 80 feet. It is situated in the fertile bottom-lands, and surrounded by cotton plantations and uplands covered with forests of yellow pine. The industries consist mainly of the manufacture of lumber, compressing and shipping cotton, and the extraction of cotton-seed oil. Population (1890), 3256; (1900), 5428, of whom 232 were foreign-born and 2834 were negroes.

Monroe, a city of Michigan, U.S.A., capital of Monroe county, in the south-eastern part of the Lower Peninsula, on the Raisin river, near its mouth in Lake Erie, at an altitude of 583 feet. Three railways, the Père Marquette, the Lake Shore and Michigan Southern, and the Michigan Central, pass through it. It has extensive and varied manufactures, largely of agricultural implements, flour, paper, &c. Population (1890), 5258; (1900), 5043, of whom 692 were foreign-born and 27 were negroes.

Monroe Doctrine.—That the United States should avoid entangling itself in the politics of Europe was a policy recommended by Washington. The counterpart of this, that European Powers should be prevented from taking a controlling share in the politics of the American continent, grew gradually as the importance and influence of the United States increased. It was announced in a concrete form, though not originated, by President Monroe. The threatened action of certain Continental Powers leagued together under the name of the Holy Alliance called out his declaration. Several of the South American colonies of Spain had asserted their independence. The Holy Alliance having helped into power a royalist insurrection in Spain, seemed about to use force to restore its revolted colonies also. To meet and check this movement, in his message to Congress in 1823 Monroe made the following pronouncement, which has ever since been styled the Monroe Doctrine:—

In the wars of the European Powers in matters relating to themselves we have never taken any part, nor does it comport with our policy so to do. It is only when our rights are invaded or seriously menaced that we resent injuries or make preparations for our defence. With the movements in this hemisphere we are of necessity more immediately connected, and by causes which must be obvious to all enlightened and impartial observers. The political system of the allied Powers is essentially different in this respect from that of America. . . . We owe it, therefore, to candour, and to the amicable relations existing between the United States and those Powers, to declare that we should consider any attempt on their part to extend their system to any portion of this hemisphere as dangerous to our peace and safety. With the existing colonies or dependencies of any European Power we have not interfered and shall not interfere. But with the Governments who have declared their independence and maintained it, and whose independence we have on great consideration and on just principles acknowledged, we could not view any interposition for the purpose of oppressing them or controlling in any other manner their destiny by any European Power in any other light than as the manifestation of an unfriendly disposition towards the United States. . . . It is impossible that the allied Powers should extend their political system to any portion of either continent without endangering our peace and happiness; nor can any one believe that our Southern brethren, if left to themselves, would adopt it of their own accord. It is equally impossible, therefore, that we should behold such interposition in any form with indifference.

Earlier in the same message, while discussing negotiations for the settlement of the respective claims of Russia, Great Britain, and the United States in the north-west, Monroe also said:—

In the discussion to which this interest has given rise and the arrangements by which they may terminate, the occasion has been judged proper for asserting as a principle in which the rights and interests of the United States are involved, that the American continents, by the free and independent condition which they have assumed and maintain, are henceforth not to be considered as subjects for future colonization by any European Powers.

With the first-quoted part of this message Great Britain was in hearty agreement.

This announcement of policy, it will be noticed, involved, firstly, a declaration aimed at foreign intervention in the political affairs of independent American states; secondly, a warning against future European colonization on the American continents. The first was avowedly based on the right of self-defence; it was a policy, not a law; it was not to constrain the minor republics, but to protect them. The second, as explained by John Quincy Adams, was intended to state the fact that the American continent was occupied by contiguous states, leaving no room for further colonization and introduction of foreign sovereignty. No legislative sanction was given to Monroe's statement of policy at the time, and in fact none was needed, for the mere announcement served to prevent foreign action in South America. Repeatedly, since 1823, efforts have been made, and have failed, to enact the principles of the Doctrine in statutory form, and repeatedly high officials of the United States have re-announced the policy. It has thus remained a policy, not a law binding to certain action. It has never formed part of the body of International Law, being unilateral. Nor has the United States bound itself by compact with the other republics on the American continent to protect them from European aggression. Thus it hesitated to send delegates to the Panama Congress in 1826, and took no part in any congress with the Latin American states until 1889.

Nevertheless, on several occasions since its conception the Monroe Doctrine has been enforced. Its spirit permeated the Clayton-Bulwer Treaty, in which Great Britain and the United States, in 1850, mutually renounced the right of colonizing, fortifying, or occupying any portion of Central America. It was enforced against Maximilian, who, by French intervention in Mexico, had been made emperor, and until the close of the American Civil War had perforce been left undisturbed. Its applicability was urged when de Lesseps's Panama Canal was thought

possible of completion. Both Cuba and the Hawaiian Islands at various periods have felt its influence, the general, though not consistent policy of the United States being, while disclaiming the desire of annexation itself, to deny the right of any European Power (except Spain in Cuba's case, until 1898) to control them. And, finally, it was applied to the claims of British Guiana to Venezuelan territory by President Cleveland's message in 1895, which proposed a commission to settle the boundary and threatened war if its line were not accepted. This commission never reported, but the disputants finally agreed to arbitrate, and the British claim was in the main upheld.

Between 1823 and 1895 the development and enlargement of this policy on the part of the United States has been very striking. To prevent the overthrow of an independent republic is one thing; to interfere in the settlement of a boundary dispute between two states, also on the ground of self-defence, is quite another. Yet Cleveland's doctrine met with general acceptance, and in fact it had been in a sense anticipated by President Grant, who, in urging the annexation of San Domingo upon the United States Senate in 1870, used this language:—

The Doctrine promulgated by President Monroe has been adhered to by all political parties, and I now deem it proper to assert the equally important principle that hereafter no territory on this continent shall be regarded as subject of transfer to a European Power.

Never having been formulated as law or in exact language, the Monroe Doctrine has meant different things to different persons at different times. It has grown with the consciousness of growth in power—a curious fact, since it is founded on the right of defending interests which must be less endangered as the United States becomes greater. It has become deeply rooted in the American heart, and a permanent part of the foreign policy of the United States. It tends to change into the principle that every portion of the American continent must be free from European control. It is still coupled, however, with the converse principle that America takes no part in European politics, as the disclaimer of the American delegates to the Peace Conference at The Hague proved.

See TUCKER'S *Monroe Doctrine*.—GILMAN'S *Life of Monroe*.—WHARTON'S *International Law Digest* (title, *Monroe Doctrine*).—SNOW'S *American Diplomacy*.—Also an article by Sir FREDERICK POLLOCK in the *Nineteenth Century and After*, 1902.

(T. S. W.)

Mons, a town of Belgium, capital of the province of Hainault, 38 miles south of Brussels. It has communication by rail with Ghent, Brussels, Charleroi, and other towns of importance. It is the centre of a rich coal district, and there are numerous sugar refineries in its vicinity. Population (communal) (1880), 24,049; (1890), 25,237; (1900), 27,015.

Montana, a north-western state of the American Union, bounded on the N. by Canada, on the E. by North and South Dakota, on the S. by Wyoming and Idaho, and on the W. by Washington, with an area of 145,310 square miles. About one-third of the state is mountainous, the remainder consisting of agricultural or grazing lands. It is no longer on the frontier, as the term was once used. Fears of Indian uprisings are gone; the Government has so systematized its management of the various tribes, by its reservations and encouragements for farming and stock-raising, that the Indians, as a rule, are content to remain within their reserves. Society has assumed a stability and permanency like that of the older states. The valleys throughout the state have been ploughed and cultivated. In manufactures, apart from the mining industry, the state has not advanced as fast as it otherwise might have done, because of the lack of

skilled labour and the inability to compete with older communities.

Population.—The population in 1890 was 132,159, of whom 87,882 were males and 44,277 females. There were 89,063 native-born and 43,096 foreign-born. There were also 10,346 Indians, not included in the foregoing figures. In 1900 the population was 243,329, showing an increase during the decade of over 84 per cent. The males numbered 149,842, the females 93,487; the native-born, 176,262; the foreign-born, 67,067; the negroes, 1523; the Chinese, 1739; the Japanese, 2441; and the Indians, 11,343. There were 26 incorporated cities, towns, and villages, of which 11 had more than 2000 inhabitants, but only 4 over 5000, namely, Butte, with 30,470; Great Falls, with 14,930; Helena, the capital, with 10,770; and Anaconda, with 9453. The average number of persons to the square mile was 1.7, as compared with 0.9 in 1890, and the urban population was 28.8 per cent. of the total.

Education.—The public schools are supported by a direct tax, which may not exceed 10 mills on the dollar of the assessment of the district. There were 678 school districts in 1899; the enrolment was 37,117, and the number of teachers was 97 male and 929 female. The sum of \$606,990 was apportioned to the 678 districts. The amount paid in 1899 for salaries was \$511,829; the value of schoolhouses was \$2,426,592. The state university at Missoula had, in 1890, 209 students and 20 instructors, the annual expenses being \$58,284. A school of mines is under organization at Butte; the state agricultural college at Bozeman, in 1899, had 173 students and 14 instructors, the annual expenses being \$23,500. The state normal school at Dillon had 45 students and 8 teachers, the annual expenses being \$16,337.

Charities, &c.—The total number of prisoners in 1899 in the state prison at Deer Lodge was 328. In the insane hospital at Warm Springs the number of patients in 1899 was 477—male, 375; female, 102. The number of inmates in the state reform school at Miles City in 1899 was 72 (60 boys, 12 girls). In 1899 the school for deaf and dumb at Boulder had 21 pupils. On 1st December 1899 there were 51 inmates in the soldiers' home at Columbia Falls. The state orphans' home at Twin Bridges cared for 106 children in 1899. The agricultural college has issued bonds to the amount of \$100,000; the normal school to the amount of \$50,000; the university to the amount of \$100,000; the deaf and dumb asylum to the amount of \$40,000. The principal and interest on these bonds are secured by the several land grants made to the state by the U.S. Government.

Libraries.—The report of the United States Commissioner of Education for 1896 shows that in five years there was an increase of 227 per cent. in the number of volumes in Montana libraries, the total number of volumes being 86,093, exclusive of pamphlets. The largest free libraries are found at Helena, 29,966 volumes; Butte, 26,984; Anaconda, 5562; Bozeman, 8000; Missoula, 4828; Billings, 3500; Great Falls, 5148; and Dillon, 2105.

Minerals.—The principal mineral products are gold, silver, copper, and lead. The following statistics give the value of the mining industry for 1889 and 1899, the figures for the latter year being subject to slight revision:—

	Gold.	Silver.	Copper.	Lead.	Total.	Per cent. Increase over Preceding Year.
1889	\$ 3,500,000	\$ 19,393,939	\$ 13,334,970	\$ 456,975	\$ 36,685,884	3
1899	4,919,896	20,040,404	39,471,000	979,000	65,410,300	21½

Coal-mining is also a valuable industry. The total value of the coal output at the mines for 1898 amounted to \$2,130,094.

Agriculture.—The agricultural products are much the same as those of the middle states, the yield, however, especially in cereals, being more abundant. The following figures show the acreage under cultivation and the yield for 1896:—

Crop.	Acreage.	Yield.
Oats	64,911 acres	3,050,770 bushels
Wheat	45,443 "	1,204,240 "
Barley	5,701 "	142,525 "
Potatoes	4,952 "	841,840 "

All grasses grow luxuriantly, and the harvest of hay from the irrigated lands is exceedingly large. In the southern valleys, on both sides of the main mountain range, both large and small fruits are grown in the greatest abundance. Fruit-growing has become a most important industry in several counties in the western part of the state. On 18th August 1894, as an inducement to the reclamation and settlement of arid lands, Congress passed the Carey Desert Land Act, which gave to the state the title to one million acres of arid lands, the title to be passed when the state should reclaim the lands. The state Legislature, by Act of 18th March 1895, formally accepted the offer, and

passed an Arid Land Act, under which an irrigation commission was appointed, and provision made for securing funds for the reclamation of all the land offered. Surveys have been made for three canals in the eastern part of the state. These canals will render arable about 75,000 acres.

Stock-raising.—During 1898, owing to high prices prevailing for young stock, a smaller number of stock cattle came into the state than formerly, the total hardly exceeding 50,000 head, a falling off of more than 75 per cent. from the preceding year. During 1899, 50,000 head of young stock were shipped into the state, a considerable increase over the previous year, but still not as many as usual. In 1890, 124,035 cattle were shipped out of the state; estimating that 50,000 were consumed within Montana, the total amounted to 174,035. In 1898, 172,225 head of cattle were shipped to various markets. Estimating the home consumption at 60,000, the total was 232,225 head. The average price was estimated at \$39 per head, an increase of about 5 per cent. over any previous year. In 1899, 143,498 head were shipped out of Montana, making a total of 203,498. The total assessed value of cattle in 1899 was \$12,057,087. On the 1st of March 1898 there were 2,967,901 sheep assessed in the state, the valuation per head being placed at \$2.52, making the total valuation \$7,450,848. The number of sheep at this time was 3,146,868. The number of sheep brought in from other states from March to December 1898 was 79,277; the number of lambs, 1,217,057. The number of sheep and lambs slaughtered, sold, and shipped from March to December 1898 was 583,320. The number of pelts sold was 450,296, the price ranging from 6 cents to 9½ cents per pound. The number of pounds of wool for the season's clip was 22,916,603, and the lowest and highest prices received by the producer were 7½ and 20 cents. In 1899 wool went as high as 22 cents. The total assessed value of sheep in 1899 was \$8,302,944. Great numbers of horses—many of the very best type of driving and draught animals—are reared. The number shipped during 1899 was 35,000, and the total assessed value of horses was \$3,289,726.

Railways.—The mileage of the chief lines of railways was as follows:—Northern Pacific railway, 1371 miles; Great Northern railway, 1066 miles; Great Falls and Canada railway, 133 miles; Oregon Short Line, 126 miles; Big Horn Southern, 101 miles; and Butte, Anaconda, and Pacific, 51 miles.

Banks.—There were at the end of 1899, 21 national banks, 13 private banks, and 14 state banks; their total capitalization and surplus was then \$5,849,393; and the total deposits amounted to \$28,732,447.

Finances.—In 1899 the assessed valuation of real property was \$72,514,960; of personal, \$54,610,006; and of railways, \$14,992,689, giving a total of \$142,117,655. On 30th November 1899 the outstanding registered general fund warrants amounted to \$349,360; accrued interest (estimated), \$5300; total debt, \$354,660. The estimated taxes and licences due and unpaid were \$357,000; cash on hand in general fund was \$7957; total, \$364,957; the estimated credit balance was \$10,297. There was no bonded indebtedness. The rate of taxation differs in each county; the average was 24½ mills in 1899 for state and county purposes; the tax for state purposes is limited to 2½ mills. The income is derived from this tax of 2½ mills, from licences, escheated estates, fees paid to state officers, inheritance tax, fines, &c. The income from all these sources (for general purposes, not for schools) for the fiscal year ending 30th November 1899 was \$571,450; the expenses amounted to \$588,727.

Manufactures.—The following table shows the manufacturing and mechanical industries as returned at the censuses of 1890 and 1900, and the percentage of increases:—

	1890.	1900.	Per cent. of Increase.
Number of establishments	289	1,080	273.7
Capital	\$4,293,794	\$40,945,846	\$853.6
Wage-earners, average number	2,386	10,117	324.0
Total wages	\$1,652,413	\$7,969,886	\$ 382.3
Cost of material used	\$2,375,093	\$32,702,650	\$1276.9
Value of products	\$5,507,573	\$57,075,824	\$ 936.3

The chief industry is the smelting and refining of copper; the total value of its products in 1900 was \$36,387,063, or over half of that of the whole state. The smelting and refining of lead and lumber and timber products rank next in importance.

Religion.—The number of members or communicants in the chief denominations was in 1890 as follows:—Roman Catholic, 25,149; Methodist, 2425; Presbyterian, 1232; Protestant Episcopal, 1104; Disciples of Christ, 785; Baptist, 683; Congregational, 345; and Lutheran, 394.

Political Changes.—Politically Montana has been irregular since its admission as a state (8th November 1889). The Republican party was slightly in the lead in 1892, Harrison having secured the electoral vote by a plurality of 1270 votes over Cleveland, out of a total vote of 44,315. In 1896 interest in silver coinage was intense, and Bryan received 42,537 votes out of 53,217 cast. In 1900 Bryan received 37,146 votes and McKinley 25,373 votes out of a total of 63,641. The Populist party polled 15,240 votes in 1894, and 11,607 votes in 1898. The state officials elected in 1896 and 1899 were principally Democratic; in 1900 the entire Fusion (Democrat-Populist) state ticket was elected. The state has not experimented much in novel legislation. There are 24 counties in Montana. The Australian ballot system prevails.

(W. H. H*.)

Montargis, chief town of arrondissement and an important railway junction, department of Loiret, 45 miles east by north of Orleans. A handsome modern building contains the town hall, public library, and museum. In the courtyard is a fine bronze group, "The Dog of Montargis," and in the town is a statue of Mirabeau erected 1888. The total port traffic in 1898 amounted to 162,579 tons. Population (1891), 9789; (1901), 10,517.

Montauban, chief town of department Tarn-et-Garonne, France, 411 miles south-south-west of Paris by rail. A monument to Leon Cladel was erected in 1895. Silk-mills give employment to a large number of work-people, and the final dressing of textiles manufactured elsewhere constitutes a special industry. Population (1891), 16,732; (1901), 30,506 (comm.).

Montauban, Charles Guillaume Marie Appollinaire Antoine Cousin de, COUNT DE PALIKAO (1796–1878), French general and statesman, was born in Paris on 24th June 1796. He entered the army as a cavalry officer, and saw much service in Algeria. His promotion was by no means rapid, and he was still but a colonel of spahis when, in 1847, he effected the long-sought capture of the famous guerilla leader, Abd-el-Kader. After rising to the rank of general of division, commanding the province of Constantine, he was appointed in 1858 to a command at home, and at the close of 1859 was selected to lead the French troops in the joint French and British expedition to China. Montauban's strategy left much to be desired, and more than once—notably at the landing near the Taku forts—the success of the allies was secured only by his yielding to the counsels of his colleague, Sir Hope Grant. After the capture of the forts the allies advanced upon Peking, scattered the huge but ill-trained Chinese army at Changkiawan and Palikao ("the Eight-Mile Bridge"), and dictated terms of peace in the capital. Montauban was made a senator by Napoleon III., and in 1862 received the title of Count de Palikao. But an indelible stain was cast upon the expedition by the plunder of the Summer Palace. Montauban himself was believed—though, as it seems, without foundation—to have acquired a vast fortune from the spoils, and on this ground the French Chamber rejected the Emperor's proposal for bestowing a large grant upon him. He remained unemployed till 1865, when he was appointed to the command of the 4th Army Corps at Lyons, in the training of which he displayed exceptional energy and administrative capacity. On the outbreak of the Franco-German war in 1870 he was not given a command in the

field, but after the opening disasters of the war had shaken the Ollivier ministry he was entrusted by the Empress-Regent with the portfolio of war, and became president of the council in a new Liberal cabinet (10th August). He at once set to work with great success to reorganize the military resources of the nation. He claimed to have raised MacMahon's force at Châlons to 140,000 men, to have created three new army corps with their equipment, 33 new regiments and 100,000 *gardes mobiles*, and to have brought the neglected defences of the capital to a state of efficiency—and all this in twenty-four days. It was he who conceived the idea of sending MacMahon's army to raise the blockade of Metz. The scheme depended for its successful execution on a precision and rapidity of movement of which the army of Châlons was no longer capable. Political reasons caused the rejection of the only sound plan, to concentrate on Paris. Upon the news of the capitulation of Sedan, the majority of the deputies offered the dictatorship to Palikao; but he refused to desert the empire. He laid before the Corps Législatif a proposal to establish a council of national defence, consisting of five members elected by the deputies, with himself as "lieutenant-general of government"; but before a decision was made, the Chamber was invaded by the mob. Palikao fled to Belgium, and subsequently offered his sword to the Government of National Defence, which declined his services. On 20th July 1871 he appeared before the parliamentary commission of inquiry, and later in the same year published a defence of his administration under the title of *Un Ministère de la Guerre de vingt-quatre jours*. He again appeared in public as a witness in the action for libel brought by General Trochu against the *Figaro* in 1872. He died at Versailles on 8th January 1878.

(H. ST.)

Montbéliard, chief town of arrondissement, department of Doubs, 46 miles east-north-east of Besançon by rail. It occupies a strategic position in the Gap of Belfort, and besides its ancient castle, now used for barracks, and a battery, is defended by outlying forts. A statue has been erected in memory of Colonel Denfert-Rochereau (d. 1878), leader of the defence at Belfort. Clocks and watches are made to the annual value of about £40,000. Population (1891), 8417; (1901), 9154.

See TÉNOT, EUGÈNE. *Les nouvelles défenses de la France; La Frontière*, 2nd ed. Bordeaux, 1893.

Montbrison, chief town of arrondissement, department of Loire, France, 22 miles north-west of St Étienne, on the railway from Clermont to St Étienne. It is situated on a volcanic hill overlooking the Vizezy, a right-bank affluent of the Lignon. The principal buildings are the church of Notre Dame (founded about 1220) and the 14th-century edifice known as Diana (Decana), restored in 1886, which serves as the meeting-place of an important archaeological society. The town has also two hospitals and a statue of the poet de Laprade (died 1883), a native of the town. Cretannes and other cotton fabrics and silk ribbons are manufactured, and there is considerable commerce in grain. Population (1881), 5803; (1901), 7520.

Montceau-les-Mines, town and railway station, arrondissement of Chalon-sur-Saône, department of Saône-et-Loire, France, 28 miles in direct line north-west of Macon. Its importance is chiefly due to its position as the centre of the Blanzay coal basin, in which about 10,000 persons are employed. Situated on the Canal du Centre, which is connected with the coalfield by numerous lines of railway, the total traffic in 1900 amounted to 436,487 tons. Various manufacturing establishments are in operation, including weaving and spinning factories, iron

and copper foundries, and engineering workshops. Population (1901), 24,690.

Montclair, a township of Essex county, New Jersey, U.S.A. It is situated in 40° 49' N., 74° 13' W., on the east incline of Watchung Mountain, in the north-eastern part of the state. Owing to its sloping site, the altitude of the town varies from 217 to more than 500 feet. The street plan is irregular. The Delaware, Lackawanna and Western, and the Erie railways give direct and frequent communication with New York, of which it is a residential suburb. Population (1890), 8656; (1900), 13,962, of whom 3071 were foreign-born and 1344 were negroes.

Mont-de-Marsan, chief town of department Landes, France, 428 miles south-west of Paris, on the railway from Bordeaux to Tarbes, and at the confluence of the Midou and the Douze (=the Midouze). The local institutions comprise a lycée, female normal school, library, and hospital. The industries include distillation of resins, forges, and manufactures of druggot and of plaster. There is trade in resin, wine, brandy, oil-seeds, haricots, young pigs, mules, and horses. Population (1881), 8178; (1901), 11,604.

The town dates from the 12th century, when it was founded by Pierre, vicomte de Marsan, as the capital of his territory, though unsubstantial claims for an earlier foundation have been advanced. In the 13th century it passed to the viscounts of Béarn, but the harsh rule of Gaston Phoebus (of whose large prison some remains exist) and some of his successors alienated the loyalty of the people and induced them to favour the English. The territory was united to the French Crown on the accession of Henry IV.

Monte Carlo. See MONACO.

Montecatini, two much-frequented mineral baths of Tuscany, Italy. (1) In the province of Pisa, 5 miles west of Volterra. The water is saline, with a temperature of 78° F. There are also copper mines, which have been worked since the 15th century. Population, about 5000. (2) In the province of Lucca, 7 miles west by south of Pistoja, in the valley of the Nievole (see Ruskin's description in *Fors Clavigera*, vol. ii.). The springs, which number ten in all, are saline, and range in temperature from 82.4° to 86° F. The water is both drunk and used for bathing by some 40,000 visitors annually, and is exported in bottles to a great quantity. There is also a large natural vapour bath (80°-95° F.) in a grotto near by, discovered in 1849. Another attraction of the place is the gardens of Collodi, a model of Italian landscape gardening. Here the Florentines were defeated by Ugucione della Faggiuola of Pisa in 1315. Population, about 7000.

Montefiascone, a town and episcopal see of the province of Rome, Italy, built on a hill (1326 feet) at the south-east of Lake Bolseno, 47 miles by rail north-west of Rome. The cathedral (1519) is one of the earliest structures by Sammicheli. The town has in San Flaviano, built in 1030, rebuilt in the Gothic style in 1262, a curious double church; in its interior some 14th-century frescoes were discovered in 1896. In the crypt is the reputed grave of the German Bishop Fugger of Augsburg, who succumbed to over-copious libations of the local wine, known as Est, est, est. Population, about 6000.

Montefiore, Sir Moses Haim (1784-1885), Jewish philanthropist, eldest son of Joseph Elias Montefiore, a London merchant, and of Rachel, daughter of Abraham Lumbroso de Mattos Mocatta, was born at Leghorn, 24th October 1784. His paternal ancestors were Jewish merchants who settled at Ancona and Leghorn in the 17th century, whilst his grandfather, Moses Haim

Montefiore, emigrated from the latter town to London in 1758. Montefiore was educated privately, and after being articled for some time to a wholesale tea merchant he entered the Stock Exchange, his uncle purchasing for him at a cost of £12,000 the right to practise as one of the twelve Jewish brokers licensed by the City of London. Although belonging to the Sephardic or "Spanish" congregation of Jews, he married in 1812 Judith, a daughter of Levy Barent Cohen, of the "German" Jews, another of whose daughters was the wife of Nathan Mayer Rothschild, the head of the great banking firm; this relationship led to a close connexion in business between Montefiore and that house, whilst, further to cement the bond existing between the two families, his brother Abraham married Henrietta Rothschild, a sister of the financier. In 1824 Montefiore, having amassed a fortune, retired from the Stock Exchange, and during the next few years assisted in founding the Alliance Fire, Life and Marine Insurance Office, the Imperial Continental Gas Association, and the Provincial Bank of Ireland. From his forty-third year to the end of his exceptionally long and active life Montefiore devoted all his energies to ameliorating the lot of his co-religionists both in the United Kingdom and in other countries. His first pilgrimage to Palestine was undertaken in 1827, and resulted in a friendship with Mehemet Ali which was to lead to much practical good, though for the moment the visit was confined to the prosecution of fruitful inquiries and the bestowal of princely alms. Immediately on his return, Montefiore began to take an active part in the struggle which British Jews were then carrying on to obtain full political and civic rights. In 1837 he became the City of London's second Jewish sheriff, and was knighted. In 1838, accompanied by Lady Montefiore, he started on a second voyage to Palestine, in order to submit to Mehemet Ali a scheme for Jewish colonization in Syria. Though political disturbances rendered his efforts again unsuccessful, the year 1840 brought Montefiore once more before Mehemet, this time to plead the cause of some Jews imprisoned at Damascus on a charge of ritual murder. He obtained their release, and on his way back wrung from the Porte a decree giving Jews throughout Turkey the utmost privileges accorded to aliens. In 1846 the threatened reissue in Russia of an Imperial ukase (first promulgated in 1844) ordering the withdrawal of all Jews from within 50 versts of the German and Austrian frontiers, caused Montefiore to proceed to St Petersburg, where in an interview with the Tsar he succeeded in getting the ukase rescinded. On his return, Queen Victoria, on the recommendation of Sir Robert Peel, made him a baronet, to mark her appreciation of his efforts in the cause of humanity and civilization. In 1859 a case of injustice which

attracted the attention of all Europe brought Sir Moses to the gates of the Vatican. A Jewish child named Mortara had been secretly baptized by its nurse and stolen from its mother, who died of grief. Cardinal Antonelli, in the name of the Pope, refused to give up the boy, who became a priest. In 1863 we find Montefiore on a mission in Constantinople to obtain from the Sultan, Abdul Aziz, the confirmation of his predecessor's decrees in favour of the Jews; in 1864 in Morocco to combat an outbreak of anti-Semitism; in 1866 in Syria, relieving the distress resulting from a plague of locusts and an epidemic of cholera; and in 1867 in Rumania, once more pleading the cause of the oppressed Jews with Prince Charles. In 1872 Montefiore was deputed by the British Jews to present to Alexander II. their congratulations on the bicentenary of the birth of Peter the Great, and was received by the Tsar with great honour at the Winter Palace. His seventh and last pilgrimage to the Holy Land was made in 1875, of which he wrote an account in his *Narrative of a Forty Days' Sojourn in the Holy Land*, published in that year. The last decade of his life was passed in comparative quiet upon his estate near Ramsgate in Kent; and there, after having received general congratulations on the completion of his hundredth year, he passed peacefully away on 28th July 1885. Sir Moses Montefiore was a strictly orthodox Jew, scrupulously observant of both the spirit and the letter of the Scriptures; in his grounds he had a synagogue built where services are still held twice a day, a college where ten rabbis live and expound the Jewish law, and a mausoleum that contains the remains of himself and of Lady Montefiore, who died in 1862. (J. A. J. DE V.)

Montefrio, a town of Spain, in the province of Granada, not far from the border of the province of Cordoba. The industries include manufactures of cotton stuffs, alcohol, and soap. The town is irregularly built, and has a modern parish church. It was an important fortress in the days of the Moorish rule, and there is a strong castle which commands the town. The population in 1897 was 10,404.

Montélimar, chief town of arrondissement, department of Drôme, France, 27 miles south of Valence, on the railway from Lyons to Marseilles. It has a communal college, library (12,000 volumes), and consultative chamber of agriculture. The industries include the manufacture of tiles and bricks, and alimentary conserves, and important saw-mills for dressed wood and parquetry. At Bondonneau, 2½ miles south-south-east, is a cold carbonated spring, utilized in a local thermal establishment. Population (1881), 8963; (1901), 13,351.

MONTENEGRO.

MONTENEGRO, or the Black Mountain (Servian *Tzrnágora*; Albanian *Mal Esiya*; the form Montenegro the Venetian variant of Montenero), though practically a free and self-governed state for more than five centuries, was for the first time formally recognized as an independent principality by the Great Powers and Turkey under the Berlin Treaty, 13th July 1878. The considerable increase of territory then accorded to the primitive little community, and the acquisition of two ports on the coast of the Adriatic, seem destined eventually to effect an important change in the character of the Montenegrins, and to modify the patriarchal customs and institutions to which they are still attached. Formerly confined to a barren tract of mountain land, and addicted exclusively to warlike pursuits, they are

*Enlarge-
ment of
bound-
aries.*

now in possession of rich well-watered plains, extensive pastures, and vast forests: the development of these new sources of wealth, as well as increased contact with the world of commerce, must sooner or later alter the conditions of life which have prevailed amongst them for so many centuries. The present frontier, which was not finally delimited till 1881, ascends the Boyana river from its mouth as far as Lake Shas, then follows the river Megured to the summit of Mount Bratovitza, reaching Lake Sentari at a spot opposite the island of Goritza Topal. Crossing the lake north-east to a point a little south-east of Plavnitza, and leaving the territory of the Hot and Klement tribes to the south, and the districts of Kutchka Kraina to the north, it passes north of the districts of Plava and Gusinye and reaches the western end of the Mokra Planina, where it

turns to the north-west. After crossing the Lim at its junction with the Skula, it coincides with the old frontier for some distance; then reaching the Tara at Maikovatz, it follows the course of that river to near its junction with the Piva: turning southwards, it reaches the old frontier once more at Klobuk, and, passing between the district of Grahovo and the Krivoshian mountains, approaches to within a few kilometres of the Bocche di Cattaro: then, following the maritime mountain ridges for a considerable distance, it rejoins the coast a little south of Spizza. The district of Spizza was occupied by Austria subsequently to the Berlin Treaty, and the political and commercial barrier interposed between the Montenegrin hinterland and the sea was thus, unfortunately, extended. The possession of Antivari and Dulcigno will, however, considerably facilitate the future economic development of the principality, notwithstanding the inconvenient situation of these ports and their present commercial insignificance. Another probable consequence of the enlargement of boundaries will be the transference of the seat of government from the mountain village of Tzetinye (usually written Cettigne) to one of the towns in the newly-acquired territory, such as Nikshitch or Podgoritzza, possessing greater advantages as a commercial and administrative centre.

In recent years the less known districts of the newly-acquired territory have been visited by several travellers, especially the finely-wooded tracts extending north of Nikshitch to the Dormitor mountain group; the remote region of the Vasoyevitchi, lying to the extreme east on either side of the upper Lim, has also been explored. The Dormitor district contains rich grassy uplands dotted with numerous small lakes, from which it derives its name of Yezera (the lakes); the rivers Tara and Piva flow through magnificent gorges clothed with rich forests, and unite near the extreme northern point of the frontier. In the district of the Vasoyevitchi, which surrounds the little town of Andriyevitzza, is the fine double peak of Kom, and, a little to the south-west, the summit of Maglitch, commanding a magnificent view over the wooded valley of Gusinye to the great Prokletia range in Albania.¹ The contrast between the rich undulating landscape of the northern regions and the sterile calcined rocks of Montenegro proper is very remarkable. The mountains of the former districts together with those of the Brda are divided into four masses: (1) the group enclosed by the Tara and Piva rivers with Dormitor, one of the highest mountains in the Peninsula (2483 metres), Yablonov Vrkh (2168 metres), and the Vrkhove Pochoratz (2012 metres); (2) the group between the Zeta and the Moratcha with Ostri-Kuk (2300 metres), Vlasulya (2296 metres), Brnik (2091 metres), and Maganik (2018 metres); (3) the ranges between the Moratcha and Tara with Sto (2232 metres), and Gradishte (2181 metres); and (4) those between the upper Tara and the upper Lim with Kom, the second highest mountain in the country (Kom Kutchki (2448 metres), Kom Vasoyevitchki (2422 metres)), separating the districts of the Vasoyevitchi on the north-east from that of the Kutchi on the south-west, and Visitor (2114 metres), on the frontier. In Montenegro proper the only prominent summit is Lovchen (1723 metres), between Cettigne and the western frontier; its dark appearance, partly due to the shadow resting on its northern and eastern declivities during the greater part of the day, and partly to the dusky pine-woods on its upper slopes, has given a name to the whole country. In the maritime districts is the Sutorman range, with the fine pyramidal summit of Rumiya (1569 metres), overhanging

Antivari. Beyond the Lim, at the extremity of the eastern frontier, is the Mokra Planina. The only extensive plains are those of Nikshitch and Podgoritzza and the lowland tract between Dulcigno and the Boyana. Montenegro proper is almost absolutely waterless, the only stream being the Rieka, which probably drains the Cettigne valley by an underground outlet: its lower course is practically an inlet from Lake Scutari, and is navigable up to the town of Rieka. The scarcity of water has largely contributed to the successful defence of the country against Turkish invasion: the few springs are hidden in deep crannies among the rocks, and the inhabitants are accustomed to preserve melted snow for use during the summer. On the other hand, the Brda and north-eastern districts are abundantly watered. Lake Scutari (350 square kilometres) is among the most beautiful in Europe; its scenery may be compared with that of Lake Garda. The water is of a light green colour, and the bed shallow (average depth 2 to 3 fathoms).

The climate generally resembles that of northern Albania; it is severe in the higher regions, and comparatively mild in the valleys, while in the maritime districts of Antivari and Dulcigno it may be compared with that of central Italy. The average temperature is about 15° (Celsius).

*Climate
and
natural
products.*

The high basin of Cettigne (638 metres) is deeply covered with snow during the winter months, and the village capital is sometimes almost inaccessible; in summer the days are hot, but the nights are cool and frequently chilly. The alpine vegetation of the summits gives way to pine forests in the sub-alpine zone (1200 to 1800 metres): below these the beech, and then the oak, the walnut, the wild pear, and wild plum make their appearance; the fig-tree, the mulberry, and the vine grow in the middle Zeta and Moratcha valleys; the myrtle, orange, laurel, and olive in the lower Moratcha region, and more abundantly in the Tzrmnitza and maritime districts. The small patches of potato-culture among the boulders, together with the stone-built huts of the inhabitants, often roofed with shingle or straw, remind the traveller of western Ireland. The vineyards produce excellent grapes, but wine production, which might become an important industry, is at present limited to home consumption. Tobacco is now largely cultivated, especially in the neighbourhood of Podgoritzza; the annual produce amounts to 250,000 kilogrammes. The leaves of the sumach (*Rhus cotinus*), which flourishes in the warmer districts, are exported for use in dye-works; the *Pyrethrum cinerariaefolium* supplies material for the manufacture of insect-powder; the fruit of the *Cornus mascula*, as well as the grape, is employed for the production of *raki*, a favourite beverage with the people. The grassy uplands of the northern and eastern districts afford magnificent pasturage; the native breed of cattle is small, but efforts are being made to improve it, and a stock-farm has been established by Prince Nicholas near Nikshitch. The horses, as elsewhere in the Balkan Peninsula, are diminutive, wiry, and intelligent. The arid rocks of Montenegro proper are infested with numerous reptiles, among them the scorpion and the dangerous *Vipera ammodytes*. Immense flocks of water-fowl haunt the upper reaches of Lake Scutari. The rivers abound with trout, tench, carp, and eels; the trout of the Moratcha are especially fine. More important from an economic point of view is the *scoranzze* (*Leuciscus alburnus*: Servian *oklievi*), a kind of sardine, which supplies an article of food and merchandise to a considerable portion of the population. The fish, which enter the Rieka inlet of Lake Scutari during the winter, are taken with nets during a few weeks in the spring, when the fishing season is inaugurated with a religious service; they are salted and exported in large quantities to Trieste and the Dalmatian coast. The annual

¹ This mountain must be distinguished from the higher Maglitch (2347 metres) on the northern frontier near the junction of the rivers Piva and Tara.

take is valued at 50,000 florins. The mineral resources of the country have not yet been investigated. Traces of iron, copper, and coal are said to exist, and a petroleum spring has been discovered.

The exports, valued at 1,179,960 florins in 1898, include cattle (large and small), smoked and salted meat known as *castradina*, cheese, undressed hides, *scoranze*, sumach, *pyrethrum*, tobacco, and wool. The imports, valued in the same year at 1,405,580 florins, consist mainly of manufactured articles, such as iron utensils and weapons, soap, candles, &c., and colonial products. An 8 per cent. *ad valorem* duty is levied on imports, and a further consumption tax of 2 per cent. The principal occupation of the people is cattle-rearing. The exportation of the animals is greatly hindered by the high tariff imposed on the Austrian frontier, which is productive of much illicit trading. Agriculture is still in its infancy, and the implements employed are of the most primitive kind. Bee-keeping is practised in the Kutchi district. There are practically no manufactures: the men disdain industrial employment, while the women are occupied by household duties or work in the fields. A brewery and a cloth factory, however, have been established at Nikshitch, a soda-water factory at Cettigne, and an olive-oil refinery at Antivari. The coarser cloth worn by the peasants is home-made; the finer kind worn by the wealthier class is imported. The progress of trade and the development of the natural resources of the country must largely depend on improved means of communication. In this direction considerable progress has already been achieved. Montenegro now possesses 180 kilometres of excellent carriage roads, admirably engineered and maintained. The remarkable zig-zag road from Cattaro to Niegush and Cettigne was completed in 1881; it has been prolonged to Rieka, Podgoritza, Danilovgrad (where a fine bridge across the Zeta was erected in 1870), and Nikshitch. Another road connects Podgoritza with its port, Plavnitza, on Lake Scutari; a third runs from Antivari to Vir-Bazar; when completed to Rieka, it will unite the sea-coast with the richest districts of the interior. The ports of Antivari and Dulcigno are insufficiently sheltered, but are capable of considerable improvement; both are places of call for the Austrian Lloyd steamers, and a regular service between the former and Bari on the Italian coast is maintained by the "Puglia" Steamship Company. The Boyana is navigable to sea-going vessels as far as Oboti (20 kilometres from its mouth), where cargoes for Scutari must be transferred to small river craft. The Anglo-Montenegrin Trading Company possesses two steamers on Lake Scutari. Postal and telegraphic communication is being rapidly extended. There are 18 post offices, and 20 telegraph stations, with 678 kilometres of wire. The telegraph, which is much used by the people (68,606 messages in 1898), will greatly facilitate the mobilization of the army. Hitherto the warriors have been summoned by stentorian couriers, who shouted from the tops of the mountains.

The population is usually estimated at about 230,000, or 25 to the square kilometre, the area being approximately 9000 square kilometres. According, however, to information officially furnished to the writer at Cettigne, the total number of inhabitants is 311,564, of whom 293,527 belong to the Orthodox Church, 12,493 are Moslems, and 554 are Roman Catholics; 71,528, or 23 per cent., are literate, and 240,036, or 77 per cent., are illiterate. The official estimate of the area is 8433 square kilometres. The population was estimated as low as 160,000 by Schwartz in 1882. It is densest in the fertile eastern districts; Montenegro proper is sparsely inhabited. The Moslems

Commerce and industries. Communications.

National characteristics.

have greatly decreased owing to emigration. The great majority of the people is of the Serb race; there are about 5000 Albanians, and 1000 gipsies. The principal towns are Podgoritza, the chief commercial centre (population about 5500); Dulcigno (5000); Nikshitch (3500); Cettigne (3200); Antivari (2500); Niegush (1800); Rieka (1500); Danilovgrad, founded by Prince Nicholas (1300); Kolashin, Vir-Bazar, Grahovo, and Andriyevitza. Cettigne, the seat of government, is a capital in miniature, possessing a palace, a theatre, foreign legations, public offices, a park, a hospital, a museum, a library, and a gaol. The little town, which a few years ago numbered only 1000 inhabitants, is rapidly increasing; the streets are regularly laid out and admirably kept. The palace, built in 1863, is an unpretending structure, but a new palace has been erected for the heir-apparent. Close by is the celebrated plane-tree, beneath which the prince gives audiences to his subjects, accepts their petitions, and settles their disputes. The adjacent Government buildings, and the monastery, which contains the tomb of the great *vladika*, Petar I., are fortified with towers. The prince possesses other residences at Niegush, Oriuluka, Rieka, and Antivari.

The Montenegrins present all the characteristics of a primitive race as yet but little affected by modern civilization. Society is still in that early stage of its development at which personal valour is regarded as the highest virtue, and warlike prowess constitutes the principal, if not the only, claim to pre-eminence. The chiefs are distinguished by the splendour of their arms and the richness of their costume; women occupy a subject position; the physically infirm adopt the profession of minstrels, and sing the exploits of their countrymen like the rhapsodists of the Homeric Age. A race of warriors, the Montenegrins are brave, proud, chivalrous, and patriotic; on the other hand, they are vain, lazy, cruel, and revengeful. They possess the domestic virtues of sobriety, chastity, and frugality, and are well-mannered, affable, and hospitable, though somewhat contemptuous of strangers. They are endowed in no small degree with the high-flown poetic temperament of the Serb race, and delight in interminable recitations of their martial deeds, which are sung to the strains of the *gusla*, a rudimentary one-stringed fiddle. Like most imaginative peoples, they are extremely superstitious, and belief in the vampire, demons, and fairies is almost universal. The physical type contrasts with that of the northern Serbs: the features are more pronounced, the hair is darker, and the stature is greater. The men are tall, muscular, and wonderfully active, displaying a cat-like elasticity of movement when scaling their native rocks; their bearing is soldier-like and manly, though somewhat theatrical. The women, on the other hand, are short and stunted, though strong, owing to the drudgery imposed on them from childhood: they work in the fields, carry heavy burdens, and are generally treated as inferior beings. In public, and even in her own house, the wife does not dare to address her husband by his name; the husband begs to be excused should he inadvertently mention his wife in conversation. In time of war the women provide the commissariat, and carry the ammunition for their male relatives. Like the Albanians, the Montenegrins take great pride in personal adornment. The men wear a red embroidered waistcoat, over which a long plaid is sometimes thrown in cold weather; a red girdle, in the folds of which pistols and yataghans are placed; loose dark-blue breeches and white stockings, which are generally covered with gaiters; the *opanka* or *opinka*, a kind of sandal, is worn instead of boots. The head-dress is a small scarlet cap (*kapa*), edged with black, in token of mourning for the disastrous battle of Kossovo, and adorned with semicircular lines of gold braid

Area and population. Towns.

enclosing the prince's monogram. A pale blue or green mantle is sometimes worn in addition by the chiefs. The poorer mountaineers are often dressed in coarse sacking, but all, without exception, carry arms. The women, as befits their servile condition, are generally clothed in black, and wear a black head-dress or veil; unmarried girls, however, are allowed to wear the scarlet *kapa*. The Vasoyevitch tribe retain the Albanian costume. The dwelling-houses are invariably of stone, except in the eastern districts, where wooden huts are found. As a rule, only the mansions of cattle-owners have a second storey: the ground floor, which is dark and unventilated, is occupied by the animals; the upper chambers, in which the family reside, are reached by a ladder or stone staircase. Chimneys are rare, and the smoke of the fireplace escapes through the windows (if any exist) or the open doorway. The principal food of the people is rye or maize cake, cheese, potatoes, and salted *scoranze*; their drink is water or sour milk; meat is seldom tasted, except on festive occasions, when *raki* and red wine are also enjoyed. The Montenegrins are great smokers: the men, whose dignity never permits them to carry burdens, may be seen going to market with the *chibuk*, or long pipe, slung across their backs. Family life presents few attractive features, owing to the degraded condition of the women: the mother possesses little influence over her sons, who are trained from their earliest infancy to cultivate warlike pursuits and to despise the weaker sex. Young men who are attached to each other are accustomed to swear eternal brotherhood (*pobratimstvo*); the bond, which receives the sanction of the Church, is never dissolved. The *zadruga*, or house-community, under the rule of a *stareshina*, or house-father, is found in Montenegro as in other Slavonic lands. The tribal system still exists, but possesses less significance than in Albania, owing to the centralization of authority at Cettigne. The tribe (*pleme*, pl. *plemena*) is subdivided into clans (*bratstva*).

Notwithstanding the creation of an elective Senate in 1831, the grant of a so-called constitution in 1868, and the establishment of a responsible ministry in 1874, the government is practically autocratic, the whole power being centred in the hands of the prince. The Senate, instituted by Petar II. with the object of limiting the power of the tribal chieftains, has now become merged in a Council of State, the members of which are nominated by the prince. The ministry comprises six departments: (1) The Interior, with separate sections for public works, posts and telegraphs, commerce and industry, shipping, sanitary service, and agriculture; (2) Foreign Affairs; (3) War; (4) Finance; (5) Justice; and (6) Education. The ministers have seats in the Council of State, of which the Minister of the Interior is *ex officio* president; they are nominated by the prince, and are responsible to him alone. A *Skupshchina*, or popular assembly, is summoned on rare occasions of national importance. For purposes of local administration the country is divided into ten *nahie* or departments, each governed by a "captain" or prefect (*okrúzhni kapetan*), who exercises judicial as well as administrative authority. The tribes, or *plemena*, eighty in number, are distributed among the *nahie*. Each is under an official, also styled *kapetan*, who holds a court of first instance. The *kapetans* of both categories are nominated by the prince. Rural communes, each under an elected *kmet* or mayor, exist in Montenegro as in all Slavonic countries. The *kmet* acts as justice of the peace, and there is an appeal from his decisions to the court of first instance. The commune comprises one or more of the *bratstva*. There is a High Court of Justice at Cettigne, from which there is an ultimate appeal to the prince. The local gendarmerie is under the control of the

kapetan. The codification of the law, which had hitherto been administered according to unwritten custom, was first undertaken by Petar I. in 1796. An improved code, issued by Danilo II. in 1855, still contained many quaint enactments. The excellent code, drawn up by Professor Bogishitch, a native of Ragusa, in 1888, was revised and enlarged in 1899. It contains elements from various foreign systems scientifically adapted to national usages and requirements. Prince Nicholas and his predecessors have made great efforts to exterminate the vendetta, or blood-feud, and to put down robbery, which, if practised by means of raids across the frontier, is not condemned by public sentiment. The death penalty was first introduced by Petar I. Executions are carried out by a firing party selected from the various tribes, in order to prevent the relatives of the criminal from exacting vengeance.

Financial statistics are not published. The total receipts are stated to amount to 1,500,000 francs—the principal sources of income being the taxes on land, houses, and cattle, the monopolies of salt and alcohol, and the customs dues. The public debt is estimated at 2,500,000 francs. The contribution of Montenegro to the Ottoman Debt has not been fixed. The prince, who under the "constitution" of 1868 relinquished the control of the state revenue, enjoys a civil list of about 200,000 francs. From time to time considerable subventions have been received from Russia and Austria.

The Montenegrin is a born warrior; his weapons, which he never lays aside, are his most precious possession, and distinction in battle is the sole object of his ambition. Brave to a fault, an unerring marksman, hardy, agile, crafty, and enduring, he has few rivals in the practice of guerilla warfare. The traditional method of fighting is by ambuscade: the enemy is enticed into some intricate defile, surrounded, and harassed by rifle-fire; then the mountaineers, throwing aside their firearms, deliver a swift attack with the *hanjar*, or *yataghan*, which they wield with terrific effect. Quarter is neither given nor expected; the wounded and the prisoners taken in battle are decapitated and their heads brought home in triumph; a number of these ghastly trophies adorned the parapet of a small tower near Cettigne as late as 1850. When reduced to extremity the Montenegrins often commit suicide rather than fall into the hands of the enemy, the last cartridge being reserved for this purpose; disabled comrades who cannot be removed are beheaded; in 1876 a Montenegrin offered to perform this friendly service for a Russian officer who was wounded at Klobuk. Savage methods of warfare, however, have been strongly discountenanced by Prince Nicholas and his predecessor. Till the middle of the 19th century the forces of the principality consisted of undisciplined bands of tribesmen under local chiefs, whose rivalries often proved injurious to the national cause. The nucleus of a permanent corps was created by Petar II., who formed a bodyguard of picked men known as *perianitzi*, from the feathers (*pera*) which adorned their caps. In 1853 Danilo II. ordered the enrolment of all persons capable of bearing arms, and instituted a military hierarchy of *voievodes* (generals), *sirdars* (colonels), and *kapetans*; the organization, which was based on the tribal system, was remodelled by Servian officers in 1870, when the chiefs were brought to Cettigne to receive military instruction. In the same year arms of precision were introduced: the cost and complex structure of the new weapons threatened to cause serious difficulty, but Russian aid was soon forthcoming. Since 1870 almost the whole supply of arms and ammunition has been provided by Russia. The military organization has undergone a gradual transformation under Prince Nicholas,

**Adminis-
tration and
justice.**

Defence.

in conformity with the changed circumstances of the country and the requirements of modern warfare. The militia organization on the tribal basis is maintained, but since 1896 a permanent battalion of 500 men has been established at Cettigne, Nikshitch, and Podgoritza, under a *komandir*, or major, 4 captains, and 15 lieutenants. It is composed of young men below the age of twenty-seven, who are drawn by lot and serve for four months; in this way a regular training is annually given to 1500 men. A permanent battery of artillery was formed in 1897, under a major, a captain, 2 lieutenants, and 18 sub-lieutenants. In time of war Montenegro can put into the field 42,000 men—the infantry is composed of 32,000 men of the first ban and 8000 of the second, or reserve; the artillery of 2000. The infantry is divided into 8 brigades, each containing from 6 to 8 battalions; the battalion is composed of a varying number of *tchete*, or companies, each of which belongs to a separate clan and has its own *bariaktar*, or standard-bearer. The younger men of the first ban are exercised in the neighbourhood of their homes on Sundays and holidays. They are armed either with the Berdan or the Moskovska (repeating) rifle. The artillery forms a brigade with 3 siege, 2 field, and 6 mountain batteries; its headquarters are at Spuzh, where the principal arsenal is situated. The *perianitzi*, whose numbers were increased by Prince Danilo, were disbanded in 1898, when a body-guard of 3000 picked men was formed and placed under the command of Prince Mirko, Prince Nicholas's second son.

The Montenegrin Church is an autocephalous branch of the Orthodox Greek communion. The *vladikas*, or prince-bishops, formerly depended on the Patriarchate of Ipek. The theocratic system of government which existed from 1516 to 1851 tended to unite the patriotic and the religious instincts of the people. Since the separation of the spiritual and temporal powers in the latter year, the see of Cettigne has been occupied by a metropolitan, styled *vladika*, who possesses a nominal jurisdiction over Scutari and the Primore, or South Dalmatian coast. There is a Roman Catholic archbishop at Antivari. The churches are small, unpretending structures, almost all exactly alike; a handsome cathedral, however, has been erected at Nikshitch. The monastic order is almost extinct; the parochial clergy, who number about 400, are only distinguishable from the laity by their beards; they wear the national costume, carry weapons, take part in warfare, and follow the ordinary avocations of the peasantry. Even the old *vladikas* discarded the episcopal robe, except when engaged in sacerdotal duties. The clergy are still for the most part extremely ignorant. The *Bogoslavia*, a seminary for the instruction of young priests and schoolmasters, was established at Cettigne in 1869. It is maintained by a subvention from the emperor of Russia, while the empress supports the *Zhenski Tzrnogorski Institut*, an excellently managed school for girls. In 1900 the number of pupils in the former was 45; in the latter, 70. In addition to these institutions there is a gymnasium, or high school, at Cettigne, with 4 classes (150 pupils in 1900). The revenues of the monasteries are now assigned to educational purposes, and primary instruction has been made obligatory for children over seven years of age. In 1900 there were 168 primary schools in the principality, with 180 teachers and 9756 pupils: of these 140 were maintained by the State and 28 by various communities; the Moslems and Roman Catholics have separate schools. The progress of education under Prince Nicholas has been very remarkable. In the time of his predecessor, Danilo II., who taught the sons of his chieftains in the palace, there were only

3 schools in the principality. In 1876, at the beginning of the war, there were 52 schools, with 62 teachers and 3159 pupils. The schools were closed during the war, and at its conclusion only 22 could be reopened, owing to want of funds. Elementary education was reorganized in 1878. An agricultural college has been founded at Podgoritza. Lecturers are appointed to explain to the peasants the advantages of learning. Higher education is still unobtainable, and the youth of the wealthier class complete their studies abroad.

The Montenegrin language is practically identical with the Serbo-Croatian; it exhibits certain dialectical variations, and has borrowed to some extent from the Turkish and Italian. Existing manuscripts and printed books, chiefly psalters and gospels, bear witness to a period of literary culture among the clergy contemporaneous with the activity of the printing-press at Obod (1493–1566). The folk-songs, however, of which the first collection was made in the reign of Petar II., constitute the bulk of the national literature. The poems of that ruler are accounted among the classics of the Servian language, especially his *Gorski Vjenatz*, a drama describing the massacre of the Montenegrin Moslems by their Christian kinsmen in 1702. The reigning family has produced a succession of poets; the songs of Mirko Petrovitch, the father of Prince Nicholas, and the lyrics and dramas of Prince Nicholas himself enjoy great celebrity. The *Grlice*, or "Turtle-doves," a kind of almanac published at Cettigne by Milakovitch between 1835 and 1839, contained poems, tales, statistics, and an abridgment of the Montenegrin annals down to 1830; it was succeeded in the time of Danilo II. by the *Orlitch*, or "Eaglet." The first Montenegrin newspaper, the *Tzrnogoratz*, or "Montenegrin," founded in 1870, was prohibited on the Austrian frontier, and soon disappeared; it was replaced by the *Glas Tzrnogortza*, or "Voice of the Montenegrin," a semi-official publication, and at present the only journal in the principality.

In Montenegro, as in Albania, the monuments of early civilization bear witness to Roman rather than to Greek influence. Roman remains occur in various parts of the country east of the Zeta, and early Latin churches exist at Dulcigno (*Ulcinium*) and other places. "The organization and forms of the churches, the architecture and ornamentation, point to the West and not to the East." It is evident that Latin civilization was firmly planted in Illyria before the barbarian incursions of the 6th century. Latin sepulchral inscriptions and some finely-cut marble blocks have been found at Berane, a little beyond the eastern frontier, and at Budimlje, in its neighbourhood. Especially interesting and important are the extensive ruins of *Doclea*, now known as Duklé, the birthplace of the Emperor Diocletian. The city, which received the franchise under the Flavian emperors, occupied a remarkable site at the junction of the rivers Zeta and Moratcha. The outer walls are standing in many places, and excavations carried out in 1893 by M. Rovinski and Mr J. A. R. Munro, Mr Milne, and Mr Anderson revealed a considerable portion of the ground-plan, including several streets and a forum. Among the buildings are a fine civil basilica, with a great inscription on the architrave, two small temples, an early Christian basilica, and a later church; several inscriptions, columns, richly-worked capitals and tracery, and mosaic pavements have been brought to light. At Medun there are remnants of polygonal masonry. Illyrian forts are found in many parts of the country. The ravages of the Turks have obliterated almost every trace of culture of the Middle Ages. A few ruins mark the site of the fortress of Obod,

Religion and education.

Antiquities.

near Rieka, where the celebrated printing-press, which sent out the Gospel to all Slavonic lands, was founded in 1493: a fragment of one of the first gospels printed here is shown at Cettigne; it bears the date 1494. Other editions are preserved at Moscow and in the monastery of Tzainitza, on the Bosnian side of the frontier.

Shortly after the accession of Nicholas (13th August 1860), an insurrection broke out in Herzegovina, and the sympathy which the mountaineers displayed with their Christian kinsmen led to a rupture with Turkey (1862). Notwithstanding the heroic defence of Ostrog by the prince's father, Mirko Petrovitch, "the Sword of Montenegro," the war proved disastrous, owing to the superior armament and discipline of the Turkish troops, and severe terms were imposed on the principality by the convention of Scutari (31st August). During the fourteen years of peace which followed, the country suffered greatly from pestilence and famine. Within this period a series of reforms were carried out by the prince: the army was rearmed and reorganized, an educational system was initiated, and a constitution under which the prince surrendered various prerogatives to the Senate was granted. In 1869 the Krivoschians, or Serb inhabitants of the northern shores of the Bocche di Cattaro, rose against the Austrian Government: the excitement in Montenegro was intense, but the prince succeeded in checking the warlike ardour of his subjects. The revolt in Bosnia and Herzegovina in 1875 had more important consequences for the principality. On the 2nd July 1876, Prince Nicholas, in alliance with Prince Milan of Servia, declared war against Turkey and invaded Herzegovina. A victory was gained at Vuchidol (28th July) and Medun was captured; but the Servian army suffered reverses, and an armistice was arranged in November. In the following spring the determination of Russia to take the field against Turkey encouraged the Montenegrins to renew the war. The Turks succeeded in occupying Ostrog, but were subsequently repulsed; the greater part of their forces was soon withdrawn to Bulgaria, and Prince Nicholas captured successively Nikshitch, Antivari, and Duleigno. The recovery of the seaboard, which had belonged to Montenegro in the Middle Ages, was perhaps the principal achievement of the war. The enlargement of territory stipulated for by Russia under the treaty of San Stefano (3rd March 1878) would have brought Montenegro into close contiguity with Servia, thus facilitating the eventual union of the Serb race and closing the path of Austria towards the Aegean. The Berlin Treaty (article xxviii.) gave to Montenegro Nikshitch, Spuzh, Podgoritza, Plava, Gusinye, and Antivari, but restored Duleigno to Turkey. The resistance of the Moslem inhabitants of Plava and Gusinye to annexation led to long negotiations, and eventually the "Corti Compromise" was agreed to by a conference of the Powers at Constantinople (18th April 1880). Plava and Gusinye were to be restored to Turkey, while the Montenegrin frontier was extended so as to include the Hot and the greater part of the Klement tribes. This arrangement, which could hardly have proved successful, was not carried out by Turkey, and the Powers subsequently decided to annex Duleigno to Montenegro in exchange for Plava and Gusinye. The Porte interposed delays, though consenting in principle, and the Albanian League (see ALBANIA) assumed a menacing attitude. On the 28th September the fleets of the Powers under Admiral Seymour appeared off Duleigno, and the British Government shortly afterwards proposed to occupy Smyrna. On the 11th November the Porte yielded; on the 22nd the Turkish troops defeated the Albanians, and on the 25th Montenegro obtained possession of Duleigno. The present frontier, as already

described, was shortly afterwards delimited by an international commission. With the exception of some frontier troubles, the years since 1880 have been spent in peace, and the country has advanced in prosperity under the autocratic but enlightened rule of Prince Nicholas. The relations with Turkey, the traditional foe, have improved, while those with Austria have become less friendly. In July 1893 the four-hundredth anniversary of the foundation of the printing-press at Obod was celebrated at Cettigne, several foreign universities and learned bodies being represented at the festivities. In September 1896 the bicentenary of the Petrovitch dynasty was commemorated.

Montepulciano, a town and episcopal see of the province of Siena, Tuscany, Italy, 44 miles south-east of Siena by rail. It crowns the summit of a hill (2074 feet), and is still surrounded by mediæval walls. Amongst its noteworthy buildings are several interesting private mansions of the 16th and later centuries, the church of the Madonna, built by Antonio da Sangallo, senior, in 1518-37, the cathedral (restored in 1888), a fountain (1520), and a 14th-century town hall, with a small picture-gallery. Montepulciano is famous for its wine, and was the birth-place of Cardinal Bellarmino (1542-1621). Population (1881), 5142; (1899), 3000.

Montereau, town and railway station, arrondissement of Fontainebleau, department of Seine-et-Marne, France, 17 miles in direct line south-east of Melun, at the confluence of the Yonne with the Seine. The church is a handsome edifice dating from the 13th century, with later additions, including the façade of the Renaissance period. The Asylum Napoléon is an institution for wounded and infirm soldiers. On the right bank of the river is the Château de Surville. The industries include a large porcelain factory, the manufacture of refractive and decorative bricks, whiting, and biscuits, and carriage-building. Population (1881), 7031; (1901), 7898.

Montereau, partly of monastic and partly of feudal origin, was in the beginning of the 15th century a place of some importance. Here, on the bridge over the Yonne, the duke of Burgundy was assassinated in the presence of the Dauphin, afterwards Charles VII., in 1419. In 1438 the town was captured by Charles VII., and during the wars of religion it was several times taken and retaken. In 1814 Napoleon gained a victory at Montereau over the Würtemberg troops under Schwarzenberg, and in memory of this his statue has been erected between the two bridges.

Monterey, a city and township in Monterey county, California, U.S.A., on the southern end of the Bay of Monterey. It is about 90 miles south-south-east of San Francisco in a direct line, and 125 miles by the railway (on the coast division of the Southern Pacific railway).

The Bay of Monterey was discovered by Vizcaino in 1602, and in 1770 a mission was established here, upon the site of which is built the present Roman Catholic church. It was at Monterey, which was the capital of California prior to the Mexican war, that the commander of a U.S. frigate hoisted the American flag and proclaimed California a part of the United States (7th July 1846). Monterey has become a popular watering-place and winter resort, on account of its mild and agreeable climate and its attractive environs. Population of the town (1890), 4677; (1900), 3420 (Pacific Grove township, with a population of 1439 in 1900, having been organized from a part of Monterey township since 1890). The population of the city in 1890 was 1662, and in 1900 it was 1748.

Monterey, a city of Mexico, and capital of the state of Nuevo Leon, situated 675 miles from the city of Mexico by railway. It is a handsome and progressive city, and the commercial centre of northern Mexico. It has important manufactories, foundries, saw mills and flour mills, and 9 miles of tramways. It possesses fine public buildings and all the conveniences of modern civilization. Population, 45,695.

Montevideo, the principal city and port of Uruguay, South America, on the north side of the La Plata, 120 miles east by south of Buenos Aires. It is the capital of the department of the same name, and had in 1892 a population of 238,080, which at the end of 1899 was estimated to have become about 250,000. The percentage of the port of Montevideo in the general foreign trade of Uruguay between 1894 and 1898 was as follows:—

	1894.	1895.	1896.	1897.	1898.
Imports	90.74	87.40	86.46	87.27	85.28
Exports	63.48	61.68	62.78	68.78	63.66

The value of the imports and exports through the same port during the same period was:—

	1894.	1895.	1896.	1897.	1898.
Imports	\$21,596,208	\$22,187,198	\$22,072,972	\$17,028,733	\$21,185,967
Exports	21,250,896	20,070,577	19,086,956	20,168,047	19,272,554

* \$=1.034 U.S. gold currency.

In 1899, 3974 vessels of 4,105,102 tons entered the port in all—foreign, coasting, and river trade. Of the entrances in 1898, 969 steamers (1,945,884 tons) were from abroad, 35 (54,694 tons) being in ballast. Extensive port improvements in the harbour, calling for an expenditure of not less than £2,100,000, have been sanctioned, including the deepening of the channel into the harbour so as to leave 24½ feet at low water, and the constructing of a careening dock over 600 feet long and of corresponding width, with 25 feet of water on the lowest beams.

Montgomery, a town and district of British India, in the Lahore division of the Punjab. The town has a railway station, about half-way between Lahore and Mooltan. Population (1881), 3178; (1891), 5159; municipal income (1897–98), Rs.15,403. It was founded in 1864, on the opening of the railway, and called after Sir H. Montgomery, then lieutenant-governor. It has a municipal high school, with boarding-house, and two literary institutions.

The district of MONTGOMERY lies in the Bari Doab, or tract between the Sutlej and the Ravi, extending also across the latter river. Area, 5754 square miles; population (1881), 426,529; (1891), 499,521; (1901), 463,585, showing an increase of 17 per cent., due to the extension of irrigation, between 1881 and 1891, but an apparent decrease of 7.2 per cent. between 1891 and 1901; average density, 80 persons per square mile. The land revenue and rates in 1897–98 were Rs.6,35,298, the incidence of assessment being Rs.0:3:8 per acre; cultivated area, 357,029 acres, of which 318,225 were irrigated, including 136,024 from Government canals;

number of police, 465; number of schools (1896–97), 168, attended by 3572 boys, being 6.8 per cent. of the boys of school-going age; death-rate (1897), 23 per thousand. The principal crops are wheat, pulse, cotton, and fodder. Camels are bred for export. The leading manufactures are of cotton and silk, and lacquered woodwork, and there are four factories for ginning and pressing cotton. The district is traversed for 82 miles by the main line of the North-Western railway, from Lahore to Mooltan; and there are 243 miles of navigable rivers. It is irrigated by the Upper Sutlej inundation canal system, and also from the Ravi.

Montgomery, a city of Alabama, U.S.A., capital of Montgomery county and of the state, on the left bank of the Alabama river, which is here navigable, in the south-east of the centre of the state, at an altitude of 162 feet. The city has a regular plan, is supplied with water by pumping by a private corporation, and is divided into six wards. It is entered by six railways, and these, with the river, give it a large commerce, principally in cotton and lumber. Its manufactures, which are of great variety, had in 1900 a total capital of \$2,930,782, and employed an average number of 2359 wage-earners. The total products were valued at \$5,035,190. The assessed valuation of the real and personal property of the city in 1900, on a basis of about three-quarters of the full value, was \$12,555,770; the net debt was \$2,050,551, and the tax-rate \$22.75 per \$1000. Population (1890), 21,883; (1900), 30,346.

Montgomeryshire, an inland county of North Wales, bounded on the N.W. by Merioneth, on the N. by Denbigh, on the E. and S.E. by Shropshire, on the S. by Radnor, and on the S.W. by Cardigan.

Area and Population.—The area of the ancient and administrative county, as given in the census returns, is 510,111 acres, or 797 square miles, with a population in 1881 of 65,710, in 1891 of 58,003 (of whom 28,222 were males and 29,781 females), and in 1901 of 54,892, the number of persons per square mile being 68.8, and of acres to a person 9.3. The area of the registration county is 589,846 acres, with a population in 1891 of 67,297. Between 1881 and 1891 the decrease of population was 11.68 per cent., and between 1891 and 1901, 5.3 per cent. The excess of births over deaths between 1871 and 1881 was 6886, but the decrease in the resident population was 8900. The following table gives the numbers of marriages, births, and deaths, with the number and percentage of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				No.	Per cent.
1880	404	2200	1402	195	8.9
1890	426	1694	1244	137	8.3
1898	425	1677	1121	131	7.8

In 1891 there were in the county 179 natives of Scotland, 130 natives of Ireland, and 42 foreigners, while 31,770 persons could speak English, 16,414 Welsh, and 15,846 English and Welsh.

Constitution and Government.—The county returns one member to Parliament, and it also includes the Montgomery district of parliamentary boroughs (consisting of Llanfyllin, Llanidloes, Machynlleth, Montgomery, Newtown, and Welshpool), which returns one member. There are four municipal boroughs: Llanfyllin (1632), Llanidloes (2769), Montgomery (1034), and Welshpool (6121). The urban districts are Machynlleth (2038) and Newtown and Llanllwchaearn (6500). Montgomeryshire is in the North Wales and Chester circuit, and assizes are held at Welshpool and Newtown alternately. The borough of Welshpool has a separate commission of the peace, but no separate court of quarter sessions. The ancient county, which is in the dioceses of Bangor, Hereford, and St Asaph, contains 59 ecclesiastical parishes or districts, and parts of 11 others.

Education.—The total number of elementary schools on 31st August 1899 was 94, of which 28 were board and 66 voluntary schools, the latter including 59 National Church of England schools, and 7 "British and other." The average attendance at board schools was 2474, and at voluntary schools 4970. The total school board receipts for the year ended 29th September 1899 were over £8412. The income under the Agricultural Rates Act was over £775.

Agriculture.—Considerably more than one-half of the total area is under cultivation, and of this about two-thirds is in permanent

pasture, in addition to which nearly 156,000 acres are in hill pasturage, while about 650 acres are under orchards and 25,000 acres under woods. Of the acreage under corn crops, which since 1880 has decreased by about a sixth, more than half is under oats, about two-sevenths under wheat, and about one-fifth under barley. The acreage under green crops is very inconsiderable, pasturage being mainly depended on for the winter forage of sheep. Nearly seven-ninths of the green crop acreage is under potatoes, and a little more than one-fifth is under turnips. Cattle are largely kept, specially for dairy purposes, and as a sheep-pasturing county it ranks after Brecon and Merioneth. The following table gives the larger main divisions of the cultivated area at intervals of five years from 1880:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1880	252,961	50,743	11,061	24,966	161,866	4322
1885	257,061	49,411	11,187	27,422	166,404	2637
1890	266,363	46,682	11,097	30,280	175,482	2759
1895	270,783	43,100	10,551	29,706	185,787	1507
1900	273,889	40,274	9,518	30,941	192,099	1004

The following table gives particulars regarding the principal livestock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1880	13,835	62,906	21,965	325,980	19,417
1885	14,827	68,902	23,692	339,997	22,575
1890	14,891	67,519	23,673	376,673	25,614
1895	15,793	69,950	22,562	367,856	27,141
1900	15,695	73,273	23,760	433,145	22,521

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 2142, as compared with 2063 in 1896. In 1899, 9371 tons of limestone were raised. Zinc has almost ceased to be raised, but barytes is mined in some quantities. The following table gives particulars of the production of lead and slate in 1895 and 1899:—

Year.	Lead.		Slate.	
	Tons.	Value.	Tons.	Value.
1890	617	£5775	1412	£3222
1899	616	6476	2191	5993

AUTHORITIES.—*Collections, Historical and Archæological, relating to Montgomeryshire* (issued by the Powysland Club). London, 1868.—*Pedigrees of Montgomeryshire Families* (published by the same club). London, 1888.—WILLIAMS. *Montgomeryshire Worthies*. Newtown, 1894.—Guide-books to North Wales. (T. F. H.)

Montignies-sur-Sambre, a town of Belgium, in the province of Hainaut, 25 miles east of Mons, with a station on a branch of the line from Charleroi to Namur. There are coal-mines in its vicinity, and the town has blast-furnaces, rolling-mills, and machine and nail factories. Population (1880), 13,326; (1900), 18,440.

Montluçon, a town of France, capital of an arrondissement of the same name in the department of Allier. It lies on both banks of the Cher, and is an important railway junction of the lines Bourges-Moulins and Mont St Sulpice-Tours-Auzances of the Orleans railway. Its close proximity to the coalfields of Commentry has greatly favoured its industrial development, which in the last few years has made rapid advances. The chief articles of manufacture are cutlery, bronze goods, and linen; in addition there are tanneries and iron forges. Population (1891), 24,911; (1901), 35,062.

Montoro, a town of Spain, in the province of Cordoba, on the river Guadalquivir. The population in 1897 had increased to 12,734. The progressive spirit of the inhabitants is shown by the well-kept streets, electric light, water conveyed by an aqueduct from mountains several miles away, public fountains, schools for both sexes,

an institute, 184 oil mills, and markets and fairs where many agricultural products and much live stock are brought from the fertile country around. Much timber is also brought from the woods in the hills. The churches of St Bartholomew, with a fine spire, San Juan de la Cruz, and San Sebastian are good specimens of Spanish church architecture of the Renaissance.

Montpelier, a city of Vermont, U.S.A., capital of Washington county and of the state, on the Winooski river, and the Central Vermont and the Montpelier and Wells River railways, in the northern half of the state, at an altitude of 484 feet. It is prettily laid out on a hilly picturesque site, and is well built. Its principal industry is the quarrying of granite in the neighbourhood. Its manufacturing establishments in 1900 employed an average number of 1019 wage-earners, and had products valued at \$1,591,958. Population (1890), 4160; (1900), 6266.

Montpellier, chief town of department Hérault, France, 490 miles south-south-east of Paris, on the railway from Bordeaux to Cette. The modern church of St Roch contains a statue of its patron, and a monument has been erected to Planchon, who did much to improve the vineyards of the surrounding district. The Palais des Facultés was opened in 1890, and the theatre rebuilt in 1883. Some 1500 students attend the university. There is a municipal library, containing 120,000 volumes and 10,000 prints and engravings. Population (1881), 45,397; (1891), 58,380; (1901), 75,950.

Montreal, a city of Hochelaga county, Quebec, and the largest city in the Dominion of Canada, situated on an island of the same name at the confluence of the Ottawa and St Lawrence rivers. The observatory in the grounds of M'Gill University stands at a height of 187 feet above the level of the sea in 45° 30' 17" N. and 73° 34' 40.05" W.—the most accurately determined position in America. The city is advantageously situated at the head of ocean navigation—the channel below the city permitting the passage of vessels drawing 27½ feet at low water—and at the eastern terminus of inland navigation, the enlarged St Lawrence canals furnishing a 14-foot waterway to the head of the Great Lakes. It is on the Grand Trunk, Canadian Pacific, Intercolonial, Canada Atlantic, New York Central, Central Vermont, and Delaware and Hudson railways, and during the season of navigation several lines of well-appointed steamers maintain communication with Liverpool, Glasgow, Bristol, Manchester, and the principal ports on the gulf and river St Lawrence and the Great Lakes. The Montreal Street (110 miles), Park and Island (36 miles), and Belt Line (12 miles) electric railways afford rapid and easy communication with all parts of the city, suburbs, and neighbouring towns. The famous Victoria bridge having proved inadequate to the traffic, and having been designed for maximum loads of less than one-half the present requirements, was replaced by the Victoria Jubilee bridge, opened in December 1898. The new structure consists of 24 spans of pin-connected "through" steel trusses, each 254 feet long, and one of 348 feet over the steamboat channel, carrying two tracks for steam railway trains and electric cars, with roadways on each side for vehicular traffic and foot passengers. The Canadian Pacific railway crosses the St Lawrence at the foot of Lake St Louis, about 6 miles above the city. The charities are numerous, and include 8 hospitals—5 Protestant and 3 Roman Catholic— orphanages, houses of refuge, deaf and dumb asylums, &c. There are 65 Protestant churches and chapels, 27 Roman Catholic, 2 synagogues, and 26 convents and monasteries. In 1898 the Roman Catholic committee controlled 17

elementary and 4 model schools, 12 academies and 3 colleges, with 871 teachers and 18,398 pupils; the Protestant committee controlled 12 elementary schools and 3 academies, with 251 teachers and 9103 pupils. McGill University, the foremost educational institution in the province, embraces the faculties of arts, law, medicine, applied science and comparative medicine, and veterinary science. In addition to the four affiliated theological colleges—Presbyterian, Diocesan, Wesleyan, and Congregational—three others, Morrin, Stanstead, and Vancouver, are affiliated in arts. Later additions to the university are the chemistry and mining, the physics and the engineering buildings, and the Royal Victoria College for women, all built and equipped on a scale of great completeness by wealthy citizens. Laval, the Roman Catholic university, includes the faculties of theology, law, medicine, and arts. There are two normal schools, a high school, two affiliated medical colleges—one with Laval and the other with Bishops College, Lennoxville,—the Jesuit college, and the seminary of St Sulpice. The city is the seat of the head offices of the Grand Trunk and Canadian Pacific railways, and of six banks—Montreal, Merchants', British North America (in Canada), Molsons, Jacques Cartier, and Hochelaga—with a total paid-up capital of \$27,000,000. It contains many flourishing industries, including manufactories of steam engines, boilers, printing-presses, musical instruments, boots and shoes, tobacco, rubber, paper, rope, glass, carriages, wooden ware, paints and drugs; also iron and brass foundries, rolling-mills, flour mills, distilleries, and breweries. The harbour is spacious; there are fine stone docks, and extensive enlargements and improvements are in progress, including an elevator with a capacity of 3,000,000 bushels and three high-level piers, each 825 feet long and 300 feet wide. In the year ending 30th June 1890 the exports from the port were \$31,660,216; in 1900-01, \$59,708,154; in 1889-90 the imports were \$45,934,406; in 1900-01, \$64,372,300, and duty collected \$9,018,660. In the year 1901, 742 sea-going vessels of 1,453,048 tons cleared for sea, and 8450 coasting vessels of 1,683,186 tons departed; total tonnage, 3,136,234 tons. In 1899 the exports of wheat totalled 13,588,098 bushels; horned cattle, 71,488; sheep, 48,073; horses, 6462; cheese, 146,285,909 lb; and butter, 28,068,280 lb. The clearances at the clearing-house amounted in 1897 to \$601,185,000, and in 1901 to \$889,479,000. The total assessment in 1885 was \$72,877,834; in 1890, \$123,891,140; and in 1902, \$188,000,000; exemptions increased from \$14,675,316 in 1885 to \$38,000,000 in 1899; total expenditure in 1901, \$3,131,920; and total receipts, \$3,570,880. In 1883 Hochelaga (population, 5000), in 1884 St Jean Baptiste (8700), in 1887 St Gabriel (7800), and in 1893 St Denis ward were annexed. Population (1881), 140,747; (1891), 216,644; (1901), 267,730; or, if the adjoining suburbs of St Henri, St Cunegonde, Westmount, &c., are included, about 335,000. (J. W.H*.)

Montreuil-sous-Bois, town, arrondissement of Sceaux, department of Seine, France, 4 miles east of Paris, on the slope and summit of a hill, about 1 mile north of Vincennes. Montreuil is now specially noted for its extensive peach orchards, covering about 590 acres and yielding annually from 12 to 15 millions of peaches. The manufactures include paint and varnish, oils, glue, soap, patent leather, and chemicals. Gypsum is quarried. Population (1891), 23,891; (1901), 31,773 (comm.).

Montrose, a royal and parliamentary burgh (Montrose group) and seaport of Forfarshire, Scotland, at the mouth of the South Esk, 30¼ miles north-east of Dundee by rail. Ropeworks and chemical works are amongst the

minor industrial features. 551 vessels of 94,462 tons entered in 1888; in 1900, 440 vessels of 51,521 tons. Imports were valued at £220,401 in 1888, and £173,221 in 1900; exports, £102,443 in 1888, and £19,106 in 1900. A new park was laid out in 1890. A museum, the infirmary, and a memorial hall have been enlarged; the new market has been converted into a public hall, and a railway viaduct built over the Esk. A Roman Catholic chapel and an additional public school have been erected. Population (1891), 12,428; (1901), 12,401. (See FORFARSHIRE for fishing statistics.)

Montserrat, one of the presidencies of the Leeward Islands, British West Indies. The population in 1881 was 10,083, in 1891 it was 11,762, and in 1901 it was 12,215. The death-rate is 25·77 per thousand. The mean shade temperature at an elevation of 400 feet is 78° to 79° F. The rainfall varies from 40 to 80 inches per annum according to situation. In 1900 the average rainfall at seven stations was 42·68 inches. Montserrat is considered one of the most healthy islands in the West Indies, being remarkably free from epidemics. The chief products are sugar and molasses, lime-juice and essential oils produced from limes. Arrowroot, coffee, and cocoa are also exported. The island offers special facilities for growing citrus fruits. It is well watered, and possesses good roads. Nearly all the lime-trees, covering about 1000 acres, principally in the northern part of the island, were uprooted by a violent hurricane on 7th August 1899. The value of the imports for the three years ending 1880 averaged £26,390; those of 1899 were valued at £14,265. The exports for the same periods were £32,963 and £12,893. The revenue in 1900 was £6664, and the expenditure £9597, the deficiency being covered by grants from the British exchequer. The public debt was £11,400. The total tonnage of vessels entered and cleared during 1900 was 198,730 (185,350 steam, 13,380 sailing). Education is nominally compulsory. In 1899 there were 7 Anglican schools with 4681 scholars, 3 Wesleyan with 672, 1 Roman Catholic with 113, and 2 undenominational with 511. Montserrat has a legislative council consisting of the governor and 6 nominated members, 3 official and 3 unofficial.

Monza, a town of the province of Milan, Lombardy, Italy, 11 miles north-east of Milan by rail. It has a polytechnic school (1889), and is the seat of a commercial court of arbitration. Population (1881), 17,000; (1899), 12,000.

Moody, Dwight Lyman (1837-1899), American evangelist, was born at East Northfield, Massachusetts, 5th February 1837. In 1855, while a salesman in the shoe trade in Boston, he was "converted," and at once became active in religious work. He continued this religious activity on his removal to Chicago in 1856, and in 1860 gave up business to devote himself to evangelizing. In 1865 he became president of the Chicago Young Men's Christian Association, and wielded a large influence also in other cities. He first became widely famous through a series of evangelistic meetings in Great Britain, held jointly with Ira D. Sankey, in 1873. After that he held similar meetings from time to time in all the important cities of the United States, visiting Great Britain again in 1881, 1883, and 1899. It is estimated that he addressed over 50,000,000 persons during his life. Beginning with a small school for girls in 1879, he developed at his home in Northfield, Mass., the Mount Hermon School for boys, the Northfield Seminary for boys, and the school for Christian workers, while, in addition, great religious conferences were held at Northfield during the summer months. During the twenty

years preceding his death, which took place at Northfield on 22nd December 1899, Moody devoted his summers to this work of religious education. Moody was a man of strong physical constitution and even temperament. He had no academic training, and his theology was that of the orthodox Church of the early middle century; but there was no sectarianism in his work, and he co-operated with men whose theological opinions he could not accept, such as Henry Drummond, George Adam Smith, and Henry Ward Beecher. The elements that constituted his strength were a rugged simplicity and absolute sincerity.

Moon.—Since the publication of the earlier volumes (ninth edition) of this Encyclopædia, a new method of working out the inequalities in the motion of the moon produced by the disturbing action of the sun has been developed and is being prosecuted to a successful conclusion. The establishment of the principle on which the method is based is due to George W. Hill. We recall that when the co-ordinates of the moon are expressed algebraically in terms of the elements of the moon's motion, they appear as an infinite series, proceeding according to the powers of four quantities, namely: e , the moon's eccentricity; i , the inclination of its orbit; ϵ , the eccentricity of the earth's orbit; and m , the ratio of the moon's mean motion to that of the earth. Of these four quantities, the first three belong to the class of elements, while the fourth may be considered as a measure of the disturbing action of the sun, as this would vanish only when the ratio m was zero. In the usual methods of treating the problem of perturbations, the investigator starts from an approximate solution in which the disturbing force vanishes, while the elements have arbitrary values. This method is justified by the general rule that, in all the ordinary cases of perturbations, the disturbing force is very small compared with the elements, and therefore a series developed in powers of that force converges very rapidly. But it happens that, in the case of the motion of the moon disturbed by the sun, the action of the sun is so considerable that the terms of the series depending on powers of m converge less rapidly than those depending on the elements. This fact suggested to Hill the idea of not starting with the elliptic orbit of the moon round the earth, but with an orbit of infinitesimal eccentricity, lying in the plane of the ecliptic, combined with a circular orbit of the earth round the sun. Supposing all the three elements we have mentioned to vanish, the only variable quantity on which the motion would depend would be the difference between the longitudes of the sun and moon. The co-ordinates of the moon relative to the earth can then be developed in a series, proceeding according to the sines and cosines of multiples of this angle. This series converges so rapidly that a few terms will suffice for a solution. Hill then assumes the orbit of the moon to have an infinitesimal eccentricity, and by an extremely ingenious process, involving the computation of a determinant with an infinite number of elements, he determines the motion of the moon's perigee numerically. His celebrated papers on this subject may be found in the *Stockholm Acta Mathematica* and the *American Journal of Mathematics*. A similar method can be applied to the motion of the moon's node, assuming the inclination of the orbit to be infinitesimal. This has been successfully done by P. H. Cowell in a paper in the *American Journal of Mathematics*, vol. xviii.

The further development and application of the method requires the terms depending on the eccentricity of the sun to be taken into account, and the terms depending on the powers and products of the moon's eccentricity and inclination to be determined. This most laborious part

of the work is being carried on by Professor Ernest W. Brown, F.R.S., an Englishman resident at Haverford College, Pennsylvania. The results of Professor Brown's work, so far as yet reached, lead to grave doubts of the numerical precision of the previous theories of the action of the sun on the moon. In the case of Delaunay's theory, this lack of precision was a necessary result of the slowness with which his series in powers of m converge. It has generally been supposed that Hansen's numerical theory—so called because purely numerical values of the four elements in question are introduced from the beginning—was free from the error arising through the slow convergence of the series used by Delaunay. But this may now be doubted. In the important case of the parallactic equation of the moon—an inequality by which the solar parallax can be determined—it seems very probable that Hansen's result is seriously in error, and that the value of the solar parallax to be deduced in this way will be appreciably smaller than that which has been derived from Hansen's numbers. Most remarkable has been Professor Brown's success in determining from pure theory the motion of the moon's perigee and node. The results he has worked out and published in the *Memoirs* of the Royal Astronomical Society accord with observations to a degree that was never before possible. His results are not, however, as yet quite definitive.

In the article in vol. xvi. of this work (p. 801) mention was made of Airy's numerical theory, which unfortunately was not brought to a conclusion by its author. The present writer inclines to the opinion that Airy's method is, so far as its general idea is concerned, a practical one, at least for the inequalities of short period, and that its execution—perhaps in a more rigorous way than its author worked it out—is one of the desiderata of lunar theory.

At the present time the most important problem connected with the moon's motion is that of the possible inequalities produced by the action of the planets, or by other causes than the action of the sun. The most complete works on this subject are those of Hill and Radau. The former published a very exhaustive determination of the inequalities due to the deviation of the earth from a spherical form (*Astronomical Papers of the American Ephemeris*, vol. iii.). Radau has essayed a complete and exhaustive redetermination of the inequalities produced by the action of the planets. It is suggestive and remarkable that neither he nor Hill has discovered any new inequality of such magnitude and period as to account for the observed deviations of the moon from its theoretical place, as they are indicated in the article in vol. xxv. on ASTRONOMY (*q.v.*). Their results accord in the main with those of previous investigators, and up to the year 1902 the cause of the observed changes of long period in the moon's mean motion remains the greatest enigma in gravitational astronomy. (S. N.)

Moon, Sir Richard, 1st Baronet (1814–1899), English railway administrator, was the son of a Liverpool merchant, and was born on 23rd September 1814. The history of his life is practically the history of the London and North-Western railway for the period in which he lived. When he first became a member of the board in 1847, the company had just come into existence by the amalgamation of the London and Birmingham, the Manchester and Birmingham, and the Grand Junction lines, and it was during his long connexion with it—first as director and then (from 1862 to 1891) as chairman—that its system was developed substantially into what it is now. The Chester and Holyhead, the Lancaster and Carlisle, and many smaller lines were gradually added to it, either by

leasing or by complete absorption, and finally in 1877 an Act was obtained consolidating all into one homogeneous whole. Throughout his career, Sir Richard Moon's powers of organization and his genius for what may be called railway diplomacy were of the greatest advantage to the company, and to him it owes in very large measure the commanding position it now enjoys. A striking feature about it is the extent to which its engines and trains are to be seen even in what might be expected to be the most private portions of other companies' lines; it was in great part Moon's prescience that secured for it the numerous running powers which it now exercises (not to mention many that are not exercised at present, though they would be if occasion required), and which contribute so much to the strength of its strategic position. An extremely hard worker himself, he expected equal diligence of his subordinates; but energy and capacity did not go unrewarded, for he made promotions, not by standing or seniority, but by merit. It thus came about that under him the North-Western was looked up to as affording a model of railway management, and the staff he trained has supplied many successful administrators to railways in all parts of the world. Sir Richard Moon, who was created a baronet in 1887, died on 17th November 1899.

(H. M. R.)

Moore, Albert Joseph (1841-1893), English decorative painter, was born at York on 4th September 1841. He was the youngest of the fourteen children of the artist, William Moore, of York, who in the first half of the 19th century enjoyed a considerable reputation in the North of England as a painter of portraits and landscape. In his childhood Albert Moore showed an extraordinary love of art, and as he was encouraged in his tastes by his father and brothers, two of whom afterwards became famous as artists—John Collingham Moore, and Henry Moore, R.A.—he was able to begin the active exercise of his profession at an unusually early age. His first exhibited works were two drawings which he sent to the Royal Academy in 1857. A year later he became a student in the Royal Academy Schools; but after working in them for a few months only, he decided that he would be more profitably occupied in independent practice. During the period that extended from 1858 to 1870, though he produced and exhibited many pictures and drawings, he gave up much of his time to decorative work of various kinds, and painted, in 1863, a series of wall decorations at Coombe Abbey, the seat of the earl of Craven; in 1865 and 1866 some elaborate compositions, "The Last Supper," and "The Feeding of the Five Thousand," on the chancel walls of the church of St Alban's, Rochdale; and in 1868, "A Greek Play," an important panel in tempera for the proscenium of the Queen's Theatre in Long Acre. His first large canvas, "Elijah's Sacrifice," was completed during a stay of some five months in Rome at the beginning of 1863, and appeared at the Academy in 1865. A still larger picture, "The Shunamite relating the Glories of King Solomon to her Maidens," was exhibited in 1866, and with it two smaller works, "Apricots" and "Pomegranates." In these Albert Moore asserted plainly the particular technical conviction which for the rest of his life governed the whole of his practice, and with them he first took his place definitely among the most original of British painters. Of his subsequent works the most notable are "The Quartette" (1869), "Sea Gulls" (1871), "Follow-my-Leader" (1873), "Shells" (1874), "Topaz" (1879), "Rose Leaves" (1880), "Yellow Marguerites" (1881), "Blossoms" (1881), "Dreamers" (1882), "Reading Aloud" (1884), "Silver" (1886), "Midsummer" (1887), "A River Side" (1888), "A Summer Night" (1890),

"Lightning and Light" (1892), "An Idyll" (1893), and "The Loves of the Winds and the Seasons," a large picture which was finished only a few days before his death. He exhibited, as well, many smaller pictures and drawings in pastel and water colours at the Royal Academy, the Grosvenor Gallery, the New Gallery, and in the galleries of the Royal Society of Painters in Water Colours, of which he was elected an associate in 1884. It has been matter for frequent remark and surprise that Albert Moore was never elected into the Royal Academy; there was certainly no lack of ability on the part of the artist to account for the neglect. He died on 25th September 1893, at his studio in Spenser Street, Westminster. Several of his pictures are now in public collections; among the chief are "Blossoms," in the National Gallery of British Art; "A Summer Night" in the Liverpool Corporation Gallery (see Plate); "Dreamers," in the Birmingham Corporation Gallery; and a water-colour, "The Open Book," in the Victoria and Albert Museum, South Kensington.

The main idea that governed Albert Moore's practice was a deliberate and intentional disregard of dramatic subject. In all his pictures, save two or three produced in his later boyhood, he avoided any approach to story-telling, and occupied himself exclusively with decorative arrangements of lines and colour masses. The spirit of his art is essentially classic, and his work shows plainly that he was deeply influenced by study of antique sculpture; but he was not in any sense an archaeological painter, nor did he attempt reconstructions of the life of past centuries. Artistically he lived in a world of his own creation, a place peopled with robust types of humanity of Greek mould, and gay with bright-coloured draperies and brilliant-hued flowers. As an executant he was careful and certain; he drew finely, and his colour-sense was remarkable for its refinement and subtle appreciation. Few men have equalled him as a painter of draperies, and still fewer have approached his ability in the application of decorative principles to pictorial art.

(A. L. B.)

Moore, Henry (1831-1895), English painter, was the ninth son of William Moore, of York, and was born in that city on 7th March 1831. His artistic education was chiefly supervised by his father, but he also attended the York School of Design, and worked for a short time in the Royal Academy Schools. He first exhibited at the Academy in 1853, and was a constant contributor to its exhibitions till his death. At the outset of his career he occupied himself mostly with landscapes and paintings of animals, executed with extraordinary detail in imitation of the prevailing taste of the Pre-Raphaelite Brotherhood; but in 1857, while on a visit to the West of England, he made his first attempts as a sea-painter. His success in this branch of practice was immediate, and it had the effect, as years went on, of diverting him almost entirely from landscapes to marine subjects. Among his most important canvases must be reckoned "The Pilot Cutter" in 1866, "The Salmon Poachers" in 1869, "The Lifeboat" in 1876, "Highland Pastures" in 1878, "The Beached Margent of the Sea" in 1880, "The Newhaven Packet" (bought by the Birmingham Corporation), and "Catspaws off the Land" (bought by the Chantrey Fund Trustees; see Plate) in 1885, "Mount's Bay" (bought by the Manchester Corporation) in 1886, "Nearing the Needles" in 1888, "Machrihanish Bay, Cantyre," in 1892, "Hove-to for a Pilot" in 1893, and "Glen Orchy," a landscape, in 1895. He was elected an associate of the Royal Society of Painters in Water Colours in 1876, and a full member in 1880; an associate of the Royal Academy in 1885.

and an academician in 1893; and at Paris, in 1887, where he exhibited "The Newhaven Packet" and "The Clearness after Rain," he received a *grand prix* and was made a knight of the Legion of Honour. He died at Margate on 22nd June 1895. His works are marked by admirable appreciation of nature, and by a rare understanding of wave-form and colour and of the subtleties of atmospheric effect; and as a sea-painter he may fairly be regarded as almost without a rival. (A. L. B.)

Moquegua, a coast department in the extreme south of Peru, divided into three provinces, Moquegua, Tacna, and Arica, of which the principal towns bear the same names. It has an area of 22,516 square miles, with a population in 1896 of 42,694. The port of Arica is in the hands of the Chilians, in accordance with the terms of the treaty of peace of 1884.

Moradabad, a city and district of British India, in the Rohilkhand division of the North-West Provinces. The city is on the right bank of the river Ramganga (655 feet above the sea), and has a station on the Oudh and Rohilkhand railway. Population (1881), 67,387; (1891), 72,921; (1901), 75,176; municipal income (1897-98), Rs.68,476, mostly derived from octroi; incidence of taxation, nearly 12 annas per head; registered death-rate (1897), 57.2 per thousand. It makes a specialty of inlaid metal-work in brass and tin, and of the weaving of chintz. There is a large trade in country produce. It is a cantonment for a native regiment. The municipality consists of twenty-three members, of whom eighteen are elected, with the magistrate as *ex officio* chairman. There are two high schools, twenty printing-presses, most of which issue vernacular newspapers, and two cotton and hemp-pressing factories.

The district of MORADABAD lies east of the Ganges and west of the native state of Rampur. Area, 2282 square miles; population (1881), 1,155,173; (1891), 1,179,398; and (1901), 1,192,348, showing an increase of 2 per cent. between 1881 and 1891, continuous since 1872, and of 1.1 between 1891 and 1901; average density, 522 persons per square mile. Mahomedans are more numerous than in any other district of the province, forming more than one-third of the total. The land revenue and rates are Rs.17,50,496, the incidence of assessment being R.1 : 2 : 7 per acre; cultivated area (1896-97), 740,735 acres, of which 107,147 were irrigated from wells, &c.; number of police, 3150; number of vernacular schools, 120, with 4820 pupils; registered death-rate (1897), 42.2 per thousand. The principal crops are wheat, rice, millet, pulse, sugar-cane, and cotton. There are no Government canals. The main line of the Oudh and Rohilkhand railway traverses the district from south to north, with branches towards Aligarh and Rampur. A third branch from Moradabad city towards Delhi was commenced in 1898, which will cross the Ganges at Gurmukhteswar by a bridge of eleven spans of 200 feet each.

Morar, town of Central India, in the native state of Gwalior, 3 miles east of Gwalior city. Population (1881), 24,022; (1891), 24,518. It was formerly a British military cantonment and residence of a political agent, but in 1886, when the fortress of Gwalior was restored to Sindhia, the troops at Morar were withdrawn to Jhansi, and the extensive barracks were likewise made over to Sindhia. It has a high school and dispensary.

Moratalla, a town of Spain, in the province of Murcia, in a mountainous district 40 miles north-west of Murcia. The streets are narrow and very irregular, but the town contains a good hospital, a theatre, and a large 17th-century parish church. There are manufactures of rough cloth, alcohol, and soap. Population (1897), 11,848.

Moravia (German *Mähren*; Bohemian or Czech, *Morava*), a margraviate and crownland in the Cisleithan part of the Austro-Hungarian Monarchy. In 1880 the population was 2,153,407, and in 1890 it was 2,276,870,

or 266 per square mile. Of these 70.03 per cent. were Slavs of the various subdivisions of the Czech race, 29.4 per cent. Germans, and the balance Slavs of other races; 95.3 per cent. were Roman Catholics, 2.7 per cent. Protestants, and 2 per cent. Jews. The proportion of females to males was 1094 to 1000. The population in 1900 was 2,435,081. In 1896 the marriage-rate was 7.92, the birth-rate 37.40, or, excluding still-births, 36.32, and the death-rate 25.24 per thousand. Of the births, 10.86 per cent. were illegitimate. Moravia is represented in the Reichsrath by 43 members, of whom 7 are returned by the universal suffrage curia; the Germans have a small majority. In the Diet the Germans are also in the majority with 55 members, the Czechs being represented by 45. The educational institutions are a polytechnic (at Brünn, with about 350 students), two theological seminaries, 48 gymnasia and *real-gymnasia*, 2556 elementary schools, and 146 continuation schools and establishments for technical education, &c. There has been a great reduction in the number of illiterates, who amounted to 54 per cent. of the Moravian recruits of 1870. They had fallen to 10.4 per cent. of the whole population in 1880, and to 6.9 in 1890. In 1898, 221 periodicals and newspapers were published (128 Czech, 88 German, and 5 polyglot). Half of the population is engaged in agriculture and forestry, a third in mining and industry, and 6.84 per cent. in trade and transport. Agriculture is prospering, particularly in those branches connected with the industries of the crownland, such as the cultivation of the beetroot (30 per cent. of the entire Austrian crop) and barley. Large quantities of wheat, rye, oats, potatoes, turnips, clover, legumes, flax and hemp, &c., are also grown. There is a considerable export of vegetables to Vienna. In the period 1880-90 pigs show the largest increase (from 205,970 to 322,239), while the number of sheep (80,706) shows a reduction of nearly half. Horned cattle numbered 677,807 (+32,600), and horses, 126,131 (+3273). The production of coal (15 million metric centals in 1898) has more than trebled, while that of lignite (1½ million metric centals) is over two and a half times as much as in 1881. The only other minerals are iron ore (109,150 metric centals), lead (360), and graphite (72,850). There were in 1898, 136 breweries and 495 distilleries, 54 sugar refineries (199,440 tons of sugar), and 6 state tobacco factories. The manufacture of woollens, silks, cotton goods, and linen is carried on in about 2000 factories, employing over 150,000 hands. According to the census of 1890, Moravia had 18 per cent. of the factories, 17 per cent. of the hands, and 16 per cent. of the motive power in Austria, thus taking the second place, after Bohemia, for industrial enterprises on the largest scale. It possessed in 1898, 1220 miles of railway, 9.9 per cent. of the total length in Austria, 7083 miles of roads, and 164 miles of waterway, of which, however, only 20 miles are navigable by boats. In the same year there were 646 post and 260 telegraph offices, with 2478 miles of line and 8410 miles of wire. Politically, the current history of Moravia is subordinate to that of the adjoining crownland of Bohemia (*q.v.*), inhabited by the same race. The Moravians, whose slight local peculiarities have almost disappeared, are on somewhat better terms with their German neighbours than their compatriots in Bohemia. In the mining districts strikes of exceptional violence have occurred.

Moravian Brethren ("The Church of the United Brethren").—This community progresses steadily, its chief characteristics being well maintained: close attention to education, strict discipline of life, and an extraordinary missionary zeal. Recently there has been a still stronger tendency towards decentralization. The three Home Provinces have now a greater independence, as the "Directing Board of the Unity," which has its seat at Berthelsdorf, near Herrnhut, only interferes in local affairs when principles are at stake. The Home Provinces now elect their own bishops. Statistics for 1899:—

	Communi- cants.	Total.	Congre- gations.
1. British Province	3,371	6,095	42
2. German "	6,294	8,159	25
3. American " (Northern)	11,776	17,857	89
4. " (Southern)	3,041	5,092	15
5. Bohemian Mission	394	627	
6. Foreign Missions	32,446	95,424	131
7. Leper Home at Jerusalem, 48 inmates.			
8. Sunday Schools (half in Mission field), 36,000 scholars, 3200 teachers.			
9. Bishops (Home Provinces)	20	Missions	5
10. Presbyters "	141	"	40
11. Deacons "	104	"	144

Morbihan, a department on the west coast of France, washed by the Atlantic Ocean.

Area, 2739 square miles. The population increased from 521,614 in 1881 to 557,934 in 1901. Births in 1899, 14,974, of which 704 were illegitimate; deaths, 10,791; marriages, 3934. There were in 1896, 754 schools, with 76,000 pupils, and the illiterate constituted 20 per cent. of the population. Out of 1,012,700 acres in 1896 of cultivated land, 671,840 acres were plough-land, and the rest divided between meadow and woodland. The wheat crop of 1899 was valued at £344,000; rye, £437,000; buckwheat, £263,000; oats, £216,000; potatoes, £201,000; natural pastures, £200,000; hemp, in harl and in seed, £32,000; cider-apples, £212,000. The live stock included 37,820 horses, 257,980 cattle, 58,700 sheep, and 51,240 pigs. The industry in metals in 1898 produced 15,200 metric tons of steel, valued at £176,000. Sardine fishing employs many hands, and is one of the sources of wealth to the department. Vannes, the capital, had 23,375 inhabitants in 1901.

Moreau, Custave (1826–1898), French painter, was born in Paris, 6th April 1826. His father was an architect, who, discerning the lad's promise, sent him to study under Picot, a second-rate artist but clever teacher. The only influence which really affected Moreau's development was that of the painter Chassériau (1819–1857), with whom he was intimate when they both lived in the Rue Frochot, and of whom we find reminiscences even in his later works. Moreau's first picture was a "Pietà" (1852), now in the cathedral at Angoulême. In the Salon of 1853 he exhibited a "Scene from the Song of Songs" (now in the Dijon Museum) and the "Death of Darius" (in the Moreau Gallery, Paris), both conspicuously under the influence of Chassériau. To the Great Exhibition of 1855 he sent the "Athenians with the Minotaur" (in the Museum at Bourg-en-Bresse) and "Moses putting off his Sandals within sight of the Promised Land." From October 1857 till September 1859 he travelled in Italy, and has left a record of the journey in a few water-colour sketches. On his return he painted "Tyrtaeus" (1860), and undertook to decorate the church at Decazeville in the Aveyron. "Œdipus and the Sphinx," begun in 1862, and exhibited at the Salon of 1864, marked the beginning of his best period, during which he chose his subjects from history, religion, legend, and fancy. In 1865 he exhibited "Medea and Jason" and "The Young Man and Death"; in 1866, the "Head of Orpheus" (in the Luxembourg Gallery); "Hesiod and the Muse," a drawing; and "The Peri," a drawing; "Prometheus" (in the Moreau Gallery); "Jupiter and Europa," a "Pietà,"

and "The Saint and the Poet," in 1869. After working in obscurity for seven years, he reappeared at the Salon in 1876 with "Hercules and the Hydra," "Saint Sebastian," "Salome Dancing" (presented to the Luxembourg by M. Hayem); and in 1878 with "The Sphinx's Riddle solved," "Jacob," and "Moses on the Nile." Moreau exhibited for the last time at the Salon of 1880, when he contributed "Helen" and "Galatea"; to the Great Exhibition of 1889 he again sent the "Galatea" and "The Young Man and Death." He took prize medals at the Salon in 1864, 1865, 1869, and 1878. He was made knight of the Legion of Honour in 1875, and officer in 1883. He succeeded Delaunay as professor at the École des Beaux Arts, and his teaching was highly popular. When he died, 18th April 1898, he bequeathed to the State his house, containing about 8000 pictures, water-colours, cartoons, and drawings, which form the Moreau Gallery, one of the best organized collections in Paris, arranged by M. Rupp, his executor and, with Delaunay and Fromentin, his closest friend.

(H. FR.)

Morecambe, or **POULTON-LE-SANDS**, a watering-place of Lancashire, England, on Morecambe Bay, 4 miles west-north-west of Lancaster by rail. A new west pier with pavilion has been constructed at a cost of £50,000. A lofty pyramidal tower with summit platform was built in 1890. It is surrounded by ornamental grounds and contains an entertainment hall. Amongst other recent buildings are a Roman Catholic church (1895) and a Wesleyan chapel (1897). The Winter Garden with its connected buildings was reconstructed in 1897 at a cost of £100,000. There is regular steam communication with Dublin and the north of Ireland. Population of urban district (Poulton, Bare, and Torrisholme) (1881), 3931; (1901), 11,798.

Morelia, a city of Mexico and capital of the state of Michoacan de Ocampo. A tramway line connects it with the station of the Central railway; 234 miles west of Mexico city. Population (1895), 33,890.

Morelli, Giovanni [IVAN LERMOLIEFF] (1816–1891), Italian patriot and critic, was born at Verona on 16th February 1816. He was educated first at Bergamo, the home of his mother, who had removed thither on the death of her husband; and then at Aarau in Switzerland. At the age of eighteen he commenced his university career at Munich, being debarred as a Protestant from entering any Italian college, and became the pupil of Ignatius Döllinger, the celebrated professor of anatomy and physiology. Natural philosophy and medicine were the studies to which he specially devoted himself, but he was also keenly interested in all scientific and literary pursuits. At Munich, and later at Erlangen, Berlin, and Paris, his brilliant gifts and independence of thought and judgment attracted the attention of the most distinguished men of the day. In Paris he became intimate with Otto Mündler, and his intercourse with that eminent art critic was not without its effect in determining the direction of his future studies; and, during a summer spent in Switzerland, he formed a friendship with Louis Agassiz, whose teaching made a deep and lasting impression upon him. On his return to Italy in 1840 he became associated in Florence with that band of patriots who were strenuously labouring for the deliverance of their country from the oppressive Austrian rule. He took an active part in the war of 1848, and was subsequently chosen by the provisional Lombard Government to plead the cause of Italian unity before the German Parliament assembled at Frankfort. In 1860, in recognition of the great services rendered to his country by Morelli, Victor Emmanuel named him a citizen of the Sardinian kingdom, and in the

following year he was elected deputy for Bergamo to the first free Italian Parliament. He was a staunch supporter of Cavour, and, though never a leading politician, exercised a considerable influence over the most prominent statesmen of the Right, who valued his sound judgment, integrity, moderation, and foresight. One of his first acts after his election was to draw the attention of Parliament to the urgent need of reform in the administration of matters relating to the fine arts. In consequence of his representations, a commission was appointed with the object of bringing under Government control all works of art which could be considered public property. The commission, of which Morelli was named president, began its work in Umbria and the Marches, and he appointed as his secretary G. B. Cavalcaselle, who was then engaged in collecting materials for a work on Italian art. According to one who knew Morelli well, much that Cavalcaselle then learned from his chief was embodied in the well-known *History of Painting*, which was published in 1864 in conjunction with Sir Joseph Crowe.

The immediate result of Morelli's first labours in the Marches was the passing of the law, which bears his name, strictly prohibiting the sale of works of art from public and religious institutions. He also endeavoured to bring about reforms in the management and organization of public galleries; but though he was repeatedly urged to accept the post of director of all these institutions, he declined any such appointment, confident that in an unofficial capacity he could better serve the cause of art. In 1873 he was named a senator of the kingdom of Italy, having voluntarily resigned his seat in the Lower House owing to the increasingly democratic tendencies of the Chamber. In Rome, the seat of the Government since 1870, he spent several months of each year; but his settled home was Milan, whither he had removed from Bergamo in 1874. Here he published some of his researches into the history of Italian art. In order to be free to speak his mind unreservedly, he determined to adopt a pseudonym and to write in German. His first contributions, a series of articles on the Borghese Gallery, were published in Lützow's *Zeitschrift für bildende Kunst* between the years 1874 and 1876. Posing as an art-loving Russian, who puts forth his opinions with the utmost diffidence, he adopted the pseudonym of Ivan Lermolieff—an anagram of his own name with a Russian termination—and described his essays as *Ein kritischer Versuch*, translated from the Russian by Johannes Schwarze, this time a Germanized form of Morelli. The originality of the method recommended by the author for studying art, the general soundness of his critical opinions, and the many new (and apparently correct) attributions suggested for pictures in the Borghese Gallery and elsewhere, attracted the attention of all students of art; but failure attended every attempt to discover the identity of the Russian critic. In 1880 Morelli published a small book under the same pseudonym, entitled, *Die Werke italienischer Meister in den Galerien von München, Dresden, und Berlin*. The appearance of this volume, which was cast in so original a form that it was altogether unlike anything which had preceded it in the realm of art scholarship, created an extraordinary sensation. The daring opinions expressed by the author struck at the roots of all existing art criticism, and were often diametrically opposed to the views of the most renowned art historians of the day. The importance of the work could not be denied, and in spite of determined opposition and searching and bitter attacks, it gained general recognition as a standard work which no serious student of art could ignore. It inaugurated a new and more scientific method of criticism, and marks an epoch in the art studies of the 19th century. The book was translated into English in 1883, with Morelli's own name

upon the title-page, and a few years later into Italian. In the decade between 1880 and 1890 he contributed three articles to German periodicals: *Perugino oder Raffael, Raffaels Jugendentwicklung, Noch einmal das Venezianische Skizzenbuch*. Being addressed to critics who had challenged his opinions, they are somewhat polemical in character, but contain a mass of information, more especially about drawings. He also wrote a skit on art connoisseurship in Europe, intending to publish it in English as the reflexions of an American on the follies of art critics in the Old World; but he never carried out his intention, though some portion of the MS. was embodied in the first part of his *Critical Studies*. This volume, the first of a series of three which, under the title of *Kunst kritische Studien*, was to contain all Morelli's contributions to art literature, was published in 1890. The first part, cast in dialogue form, contains a detailed exposition of his method. Then follow the *Borghese Gallery*, a reissue of his former articles with many important additions, and *The Doria Gallery*, an entirely new contribution. The second volume deals with the galleries of Munich and Dresden, and is a revised edition of the first two parts of the original book of 1880; but here again copious additions rendered it practically a new book. The third volume was to treat of the Berlin Gallery, and was also to contain an exhaustive account of the drawings of Italian masters, but it was destined never to be carried out. Morelli was taken seriously ill towards the middle of February 1891, and was found to be suffering from heart disease and other complications; a fortnight later he died at Milan, on 28th February. His collection of drawings by the old masters he bequeathed to his pupil, Dr Frizzoni, and his pictures, over one hundred in number, to the city of Bergamo, where they are now exhibited as the Galleria Morelli in two rooms of the Accademia Carrara. A striking half-length portrait by Lenbach, who presented it to his friend in 1886, forms part of the collection. In memory of Morelli a bronze bust of him by a Milanese artist has been placed in the Brera; but his features are more worthily presented in a second portrait by Lenbach and in a lifelike pastel sketch executed by the Empress Frederick in 1884, when he was her guest at Baveno. After the death of Morelli the first two volumes of his *Critical Studies* were published in English, Sir Henry Layard, one of his most intimate friends, contributing to the first a biographical sketch of the author; and the fragmentary MS. of the third volume was published in German by Dr Frizzoni, under whose editorship an Italian translation of the first volume has also been issued.

Morelli found art criticism uninspired, unscientific, and practically worthless. To be of any real value he held that historical, documentary, and traditional knowledge respecting works of art was only of secondary importance as compared with the evidence to be derived from the study of the pictures themselves. He contended that art criticism must be conducted on scientific principles and follow a strict course of inductive reasoning. A painting should be subjected to a searching analysis, and its component parts and minutest details submitted to methodical and exact investigation. Æsthetic considerations had their value, but they had been given an undue weight, to the neglect of other factors of equal or even greater force. Before his day critics had been mainly guided by the subjective impression produced upon them by the work of art as a whole, while the form—that is, the individual and component parts which contribute to the unity of the whole, and through which the spirit of the master finds expression—was entirely ignored.

The study of the individual parts and forms was, in his estimation, of the highest importance, for they were not mere incidents, but the outward and visible seal of an artist's character stamped upon his work, and obvious to all who had eyes to see. By diligent observation of the forms the rudiments of the language of art might be mastered, and the first step taken towards initiating a methodized system of study. The education of a critic consists chiefly in learning to compare, and Morelli soon recognized the value of systematic comparison in the study of art. By the combined methods of critical analysis and comparative observation, he found the clue he had so long been seeking. Studying one day in the Uffizi, it suddenly struck him that in a picture by Botticelli containing several figures the drawing of the hands was remarkably similar in all; that the same characteristic but plebeian type, with bony fingers, broad square nails, and dark outlines, was repeated in every figure. Turning to the ears, he observed that they also were drawn in an individual manner, and that in the numerous figures in which the ear was visible the same typical form recurred. Having noted these fundamental forms, he proceeded to an examination of other works by this painter, and found that the same forms were exactly repeated, together with other individual traits which seemed distinctive of the master; the characteristic type of head and expression, the drawing of the nostrils, the vitality of movement, the disposition of drapery, harmony of colour (where it had not been tampered with by the restorer), and quality of landscape. In all Botticelli's true works the presence of these and other characteristics proclaimed their genuineness. In paintings where the forms and types were those of the painter, but where vitality, movement, and all deeper qualities were absent, Morelli recognized works executed from the master's cartoons; while in pictures where neither types nor forms responded to the test, and where only a general family likeness connected them with Botticelli, he discerned the productions of pupils and imitators. After applying his method to the works of Botticelli, he proceeded to examine those of other Florentine masters, and afterwards of painters of other Italian schools, everywhere meeting with results to him not less convincing. If the drawing of the hand and ear were not always conspicuous, there were other peculiarities of this language of form to aid in the identification of a master: the treatment of the hair, as in Piero dei Franceschi; the indication of the sinews, as in Foppa; the drawing of the eye, as in Liberale da Verona; the modelling of the eyelid and upper lip, as in Ambrogio de Predis; the form of the feet, as in Luini. In short, all apparently insignificant details were of importance in his plan of study, for to him they were like the signature of the master. He held them to be of far greater value for purposes of identification than the general external aspect of a picture and its supposed technical qualities and colouring; for, after having been exposed for centuries to countless processes of cleaning, repainting, and varnishing, pictures, as a rule, retain but little of their original aspect, and it is only in the forms that the master's personality may still be recognized.

This is a brief outline of Morelli's method from its purely practical and mechanical side, but he did not overlook those deeper qualities to which the vague designation of "spirit" in a work of art is given. Only he maintained that side by side with the psychological study of it must ever be practised a close and systematic study of the form; for, to quote his own words, "it is only through unremitting study of the form that we may gradually attain to understanding and recognizing the spirit which gives it life."

(C. J. F*.)

Morelos, a state of Mexico, bounded by the Federal district on the N., by the state of Mexico on the W., N.W., and N.E., by Puebla on the E. and S.E., and by Guerrero on the S. and S.E., with an area of 2774 square miles. The population in 1879 was 159,160, and in 1900 it was 161,697. Though small it is progressive, and one of the richest agricultural states in the Republic. The principal products are sugar-cane, rice, maize, coffee, and wheat. The sugar-cane products in 1897 were valued at \$5,800,000. Its fruit exports are also very large. The Interoceanic railway traverses the state from north-east to south-west. The state is divided into six districts. The capital, Cuernavaca, had 8747 inhabitants in 1895. Amongst other towns are Yauztepec (6756), Morelos (or Cuautla) (5538), Joncatepec de Leandro, Jojutla de Juarez, and Tetecala de la Reforma.

Morgan, John Pierpont (1837—), American banker and capitalist, was born 17th April 1837, at Hartford, Conn. He was the son of Junius Spencer Morgan, a partner of the London banker and philanthropist, George Peabody. He received his education at the English High School, Boston, and the University of Göttingen, engaged in banking in New York, and in 1864 organized the firm of Dabney, Morgan and Co. In 1871 he united with Anthony Drexel of Philadelphia to form the firm of Drexel, Morgan and Co., of which he became in 1893 the senior partner. In 1895 the name of the firm was changed to J. P. Morgan and Co. In 1860 he was made American representative of George Peabody and Co. of London, and ultimately became the head of J. S. Morgan and Co., its successor, as also of Morgan, Harjes and Co. of Paris, and Drexel and Co. of Philadelphia. He has been especially successful in the reorganization of a number of bankrupt American railways, among them the Erie, Philadelphia, and Reading; New York and New England; Southern; Northern Pacific; and Baltimore and Ohio. In 1895 a large part of the \$65,000,000 United States Government bond issue was taken by his firm. Being in command of huge financial resources, Mr Pierpont Morgan became the prime mover in the organization of the principal great Anglo-American and American commercial combinations which came into existence at or about the opening of the 20th century. His enterprise was notably employed in connexion with the formation of the United States Steel Corporation (which took over Mr Andrew Carnegie's business and others), the harmonization of coal and railway interests in Pennsylvania, and the purchase first of the Leyland line of Atlantic steamers, and then (1902) of other British companies (including the "White Star"), and the formation of a huge Atlantic shipping combination; and his name became a household word in connexion with similar schemes of gigantic commercial amalgamation. Among his benefactions were \$1,000,000 to the lying-in hospital of New York, \$500,000 to the New York trade schools, and \$1,000,000 to Harvard University. He also bought works of art on a princely scale, his picture purchases including the famous (recovered) "Duchess of Devonshire" by Gainsborough, and the Colonna Raphael. He married in 1865 Frances Louise Tracy of New York City.

Morier, Sir Robert Burnett David (1826—1893), British diplomatist, was born at Paris on 31st March 1826. He was descended from a family of diplomatists of Huguenot origin, the best known of whom were his father David, consul-general for France and minister at Bern, and his Uncle James, the author of *The Adventures of Hajji Baba*. After a somewhat defective private education, he came up to Balliol College, Oxford. Here he attracted the notice of Jowett, under whose

influence his brilliant but wayward mind obtained the discipline of which it stood in need. The relation of tutor and pupil developed into a friendship of rare warmth. Writing towards the close of his life, Jowett, who inspired more devoted friendships than any other man of his time, spoke of Morier as his kindest and best friend for forty-five years, and his correspondence teems with discussions between the two friends on every topic of the day. On leaving Oxford, Morier at first obtained an appointment in the Education Department, but resigned in 1852, and in the following year became attaché at Vienna. In the succeeding years he was attached in turn to almost every court in Germany. Restless in temperament and unconventional in method, he plunged into the vortex of German politics to a degree that did not always accord with the traditions of diplomacy. The most important years of his career in Germany were from 1866 to 1871, when he was secretary of legation at Darmstadt. Here he became a trusted adviser of the crown princess, and through her acquired an intimate friendship with the crown prince (afterwards the Emperor Frederick III.), whose antagonism to Bismarck's reactionary policy met with cordial support from Morier's sturdy Liberalism. Bismarck, already jealous of British influence at court, honoured Morier with a hatred not lessened by the fact that Morier's knowledge of German politics was unrivalled outside Germany. On leaving Darmstadt, Morier became chargé d'affaires, first at Stuttgart and then at Munich, and in 1876 was appointed minister at Lisbon. From 1881 to 1884 he was minister at Madrid, and distinguished his term of office by the negotiation of an important commercial treaty. In December 1884 he became ambassador at St Petersburg, and almost immediately had to face the alarming situation created by the Russian advance to Penjdeh. Thanks to his efforts, a war that at one moment seemed inevitable was averted. His great popularity at the Russian court contributed towards a marked improvement in the relations between the two countries. Bismarck took alarm at the lessening influence of Germany over Russia, and, always relentless in his hatreds, tried to procure Morier's downfall. The *Kölnische Zeitung* declared in December 1888 that Morier had made use of his position at Darmstadt during the Franco-German war to betray the movements of the German troops to Marshal Bazaine. The authority for this charge was an alleged declaration made by Bazaine to the German military attaché at Madrid. Bazaine had died in September, but Morier had heard rumours in July of the charge brought against him, and had procured from Bazaine a written denial, which he now published in *The Times*. Apart from this, it was clearly shown that Morier could not have transmitted the information by the alleged date, and that Bazaine, according to the testimony of his own books and of other officers, received the information in question by reports from the front. As a matter of fact, Morier was an ardent champion of the German cause. His correspondence with Jowett shows the latter vainly endeavouring to convince his friend that the French were in the right. Public opinion everywhere, except in the German Conservative press, attributed the charge to political motives. This was confirmed by Bismarck's subsequent attempt to implicate Morier in the Geffcken case—a fresh instance of the Chancellor's bitterness against the Emperor Frederick and all his friends. The international importance of the affair was shown in the following February, when a grand ball given by Morier was attended by the Tsar and the whole Imperial family. Morier's failing health caused him, at his own request, to be appointed Lord Dufferin's successor at Rome in 1891; but it was felt that he could not be spared from St Petersburg, and there

he remained till forced to find a milder climate. It was then too late, and he died at Montrenx in Switzerland on 16th November 1893. (H. sv.)

Morison, James Augustus Cotter (1832–1888), British author, was born in London on 20th April 1832. His father, who had made a large fortune as the inventor and proprietor of "Morison's Pills," settled in Paris till his death in 1840, and Cotter Morison thus acquired not only an acquaintance with the French language, but a profound sympathy with France and French institutions. In later life he resided for some years in Paris, where his house was a meeting-place for eminent men of all shades of opinion. He was educated at Highgate Grammar School and Lincoln College, Oxford. Here he fell under the influence of Mark Pattison, to whom his impressionable nature perhaps owed a certain over-fastidiousness that characterized his whole career. He also made the acquaintance of the leading English Positivists, to whose opinions he became an ardent convert. Yet he retained a strong sympathy with the Roman Catholic religion, and at one time spent several weeks in a Catholic monastery. One other great influence appears in the admirable *Life of St Bernard* which he published in 1863—that of his friend Carlyle, to whom the work is dedicated, and with whose style it is strongly coloured. Meanwhile he had been a regular contributor, first to the *Literary Gazette*, edited by his friend John Morley, and then to the *Saturday Review* at its most brilliant epoch. In 1868 he published a pamphlet entitled *Irish Grievances shortly stated*. In 1878 he published a volume on *Gibbon* in the "Men of Letters" series, marked by sound judgment and wide reading. This he followed up in 1882 with his *Macaulay* in the same series. It exhibits, more clearly perhaps than any other of Morison's works, both his merits and his defects. Macaulay's bluff and strenuous character, his rhetorical style, his unphilosophical conception of history, were entirely out of harmony with Morison's prepossessions. Yet in his anxiety to do justice to his subject, he steeped himself in Macaulay till his style often recalls that which he is censuring. Against this power of sympathy, which Mr Frederic Harrison calls the greatest of Morison's gifts, must be put a want of robustness, sometimes amounting to hypercriticism, as in his remarks on Macaulay's poetry. It was this over-refinement, coupled with delicate health, that kept him from committing to paper his researches on the history of French institutions. These researches formed the chief occupation of his life, and would, as his friends believed, have obtained from the world a recognition of powers which his published works did not adequately reveal. His brief sketch, *Mme. de Maintenon: une étude* (1885), and some magazine articles, were the only fruits of his labours in French history. Towards the close of his life he meditated a work showing the application of Positivist principles to conduct. Unfortunately, failing health compelled him to abandon the second or constructive part: the first, which attempts to show the ethical inadequacy of revealed religion, was published in 1887 under the title of *The Service of Man*. Though containing many impressive passages, and animated by a lofty spirit, it can only be regarded as a restatement of familiar arguments, and bears marks, in a certain want of proportion, of the haste with which it was completed; but it was widely read, and made his name known to a larger public. He died in London on 26th February 1888. (H. sv.)

Morlaix, chief town of arrondissement, department of Finistère, France, 52 miles north by east of Quimper, on the railway from Paris to Brest. The tobacco factory employs about 100 men and 700 to 800 women, and the

output of tobacco amounts annually to over 5,000,000 lb. The total port traffic in 1899 amounted to 53,289 tons. Population (1891), 13,259; (1901), 16,086.

Morlanwelz, a town of Belgium, in the province of Hainaut, 15 miles east of Mons by rail. There are foundries, forges, and other iron industries in the town, and coal-mines in the vicinity. Population (1890), 7307; (1900), 7895.

Morley, a municipal borough (1885) in the Morley parliamentary division of Yorkshire, England, 4 miles south-south-west of Leeds, on the Great Northern and London and North-Western railways. The gas works were taken over by the corporation in 1898, and extensive waterworks were completed in 1894. A new town hall was opened in 1895; a park, for which the ground was presented by Lord Dartmouth, has been laid out; public baths have been erected, and other important improvements effected. The chief industries are connected with woollen cloth, machinery for the treatment of wool, coal and stone. The town figures in Domesday Book. Population (1891), 21,068; (1901), 23,636.

Morley, Henry (1822–1894), British man of letters, was born in London on 15th September 1822. After unhappy experiences at English schools, he was sent to the Moravian school at Neuwied, whose system strongly influenced his subsequent theories of education. It was intended that he should follow his father's profession of medicine, and in 1844 he bought a share in a practice at Madeley, Shropshire. Plunged into debt by his partner's dishonesty, he set up a small school for young children at Liscard, near Liverpool. His principle was to abolish all punishment, to make his pupils regard their work as interesting instead of repellent, and to form their character by appealing exclusively to higher motives. This scheme, carried out with much ingenuity, proved a complete success. Meanwhile he had devoted his spare time to writing. He long cherished the ambition of making his mark as a poet, and in 1845 published *The Dream of the Lilybell*, followed in 1848 by *Sunrise in Italy*. His muse was fluent, but wanting in distinction, and it was fortunate for his reputation that necessity compelled him to turn to other pursuits. His contributions to magazines on sanitation and other subjects attracted the notice of Charles Dickens, on whose invitation in 1851 he settled in London as a regular contributor to *Household Words*. He was also on the staff of the *Examiner*, which he edited from 1861 to 1867. Meanwhile he had devoted much research to a life of *Palissy the Potter* (1852), which was at the same time a picture of life in mediæval France. Encouraged by its favourable reception, he followed it up with lives of *Jerome Cardan* (1854) and *Cornelius Agrippa* (1856), and subsequently of *Clement Marot* (1870). His dramatic criticisms were reprinted in 1866 under the title of *The Journal of a London Playgoer, 1851–1866*. In 1857 he was appointed evening lecturer in English literature at King's College, and in 1865 became, in succession to David Masson, professor of English literature at University College, London. Deciding to devote his life-work to this subject, he published in 1864 the first volume of a monumental history of English literature entitled *English Writers*, which he eventually carried in eleven volumes down to the death of Shakespeare. He was indefatigable as a popularizer of good literature. After editing a standard text of Addison's *Spectator*, he brought out a vast number of classics at low prices in Morley's Universal Library, Cassell's National Library, and the Carisbrooke Library. His introductions to these display his characteristic tendency to dwell on the

ethical rather than the literary merits of his authors. His ready speech, retentive memory, earnest purpose, and bright style made him perhaps the most popular lecturer of his day, and the influence exerted by his countless lectures all over the country was second only to that of his cheap reprints. His teaching work at University College was marked by equally extraordinary success. In 1882 he accepted a post that made great calls on his time and energy—the principalship of University Hall. This institution was partly a place of residence for students of University College, and partly the home of Manchester New College. During this time he rendered further services to the cause of education in London not only by his work on the council of University College, but by his advocacy of a teaching university for London. In 1889 he resigned the principalship of University Hall and his professorship at University College, and retired to Carisbrooke, Isle of Wight, intending to devote his leisure to the completion of the great task of his life, *English Writers*. But with his work only half achieved he died on 14th May 1894. (H. S.)

Morley, John (1838—), English statesman and author, was born at Blackburn, 24th December 1838, being the son of Jonathan Morley, surgeon. He matriculated at Lincoln College, Oxford, in 1856, and after taking his degree in 1859 came up to London with the determination of seeking distinction by literature. He almost immediately became editor of the moribund *Literary Gazette*, which not all his ability could preserve from extinction. Gradually, however, he became known as a philosopher and a Radical, and as one of the ablest and most incisive contributors to the literary and political press of the day. His sympathies as a thinker seem to have been at this time chiefly with Positivism, though he never embraced Comte's doctrine in its hierarchical aspects; but he acquired a reputation as an agnostic, which became confirmed in the popular mind when he somewhat aggressively spelt God in one of his essays with a small "g." In 1868 he was editor for a short time of the daily *Morning Star*, which came to an end in 1870. In 1867 he succeeded Lewes in the editorship of the *Fortnightly Review*, which he conducted with brilliant success until 1883, when he was elected to Parliament; he then assumed in exchange, but not for long, the lighter duties of the editorship of *Macmillan's Magazine*. He had been connected with Messrs Macmillan since the commencement under his editorship, in 1878, of the "English Men of Letters" series, a collection of biographies of various merit, in which nothing is better than the editor's own contribution in his *Life of Edmund Burke*. Since 1880 he had been the editor of the *Pall Mall Gazette*, which was then turned into a Liberal paper (see NEWSPAPERS); and he succeeded in ably maintaining the high character with which it had started under Mr Greenwood. In 1883 Mr Morley, who had twice unsuccessfully attempted to enter Parliament, was returned for Newcastle-upon-Tyne at a bye-election. The prestige thus acquired led to his presiding over a great Liberal congress at Leeds in the same year; and, although the platform never seemed his natural element, the literary finish of his style and the transparent honesty of his reasoning rapidly gained him a prominent position in the House of Commons. When, in February 1886, Mr Gladstone returned to office as a Home Ruler, Mr Morley, who had never before held any public appointment, filled one of the most important posts in the Cabinet as Secretary for Ireland. He had always expressed his sympathy with the Irish Nationalist movement. He had no opinions to recant, no pledges to explain away. He is credited with an especial influence over Mr Gladstone in the matter of Home Rule, and in particular with having

kept him steady in the Bill of 1886 to his original purpose of entirely separating the Irish from the British legislature, a provision which pressure from their own party afterwards compelled both Mr Morley and Mr Gladstone to abandon. After the severe defeat of the Gladstonian party at the general election of 1886, Mr Morley led a life divided between politics and letters until Mr Gladstone's return to power in 1892, when he resumed his former office. He had been re-elected for Newcastle in circumstances entirely honourable to himself, a determined attempt having been made to exclude him in consequence of his resistance to an Eight Hours' Labour Bill, of which he disapproved as an undue interference in principle with the rights of adult labour. His constituents showed their appreciation of his integrity by returning him with a majority of 1739; but the resistance to his views on the labour question went on in his constituency, and was assisted by Mr Cowen's persistent cam-

ment policy towards the Boers and towards the war, though not representing the popular side, always elicited a respectful hearing, if only for the eloquence of their language and the undoubted sincerity of the speaker.

As a man of letters Mr Morley's place will be determined by his monographs on *Voltaire* (1872), *Rousseau* (1873), *Diderot and the Encyclopædists* (1878), *Burke* (1879), and *Walpole* (1889). Burke as the champion of sound policy in America and (as Mr Morley deems) of justice in India, Walpole as the pacific minister understanding the true interests of his country, fired Mr Morley's imagination. His *Life of Oliver Cromwell* (1900) revises Gardiner as Gardiner revised Carlyle. The *Life of Cobden* (1881) is an able defence of that statesman's views rather than a critical biography or a real picture of the period. Mr Morley's contributions to political journalism and to literary, ethical, and philosophical criticism are numerous and valuable. They rarely evince any striking originality of thought, but possess great individuality of character. As in letters, so in politics. A philosophical Radical of a somewhat mid-19th-century type, and highly suspicious of the later opportunistic reaction (in all its forms) against Cobdenite principles, he yet retained the respect of the majority whom it was his usual fate to find against him in English politics by the indomitable consistency of his principles and by sheer force of character and honesty of conviction and utterance. After the death of Mr Gladstone Mr Morley was engaged till 1902 upon his biography. Among the Coronation honours of 1902, he was nominated an original member of the new Order of Merit; and in July 1902 he was presented by Mr Carnegie with the late Lord Acton's valuable library.

JOHN MORLEY.

(From a photograph by Elliott and Fry.)

paign in the principal Newcastle newspaper against the general lines of Mr Morley's somewhat doctrinaire and anti-Imperialistic views on politics. The result was that, at the election of 1895, he lost his seat, but soon found another in Scotland, for the Montrose Burghs. He had during the interval taken a leading part in Parliament, but his tenure of the chief secretaryship of Ireland was not a success. The Irish gentry, of course, made things as difficult for him as possible, and the path of an avowed Home Ruler installed in office at Dublin Castle was beset with pitfalls. In the intestine disputes which agitated the Liberal party during Lord Rosebery's administration, and afterwards, Mr Morley sided with Sir William Harcourt, and was the recipient and practically co-signatory of his letter resigning the Liberal leadership in December 1898. Mr Morley's activities were again turned to literature, the political views most characteristic of him, on the Boer war in particular, being practically swamped by the overwhelming predominance of Unionism and Imperialism. His occasional speeches, however, denouncing the Govern-

Morley, Thomas (1557-1603), English musical composer, was born in 1557, as may be gathered from the date of his motet, "Domine non est," composed "aetatis suae 19 anno domini 1576," and preserved in Sadler's Part-Books (Bodleian Library). He was a pupil of William Byrd, but nothing is known as to his origin and very little as to the incidents of his career. In the account of the entertainments given at Elvetham by the earl of Hertford in 1591 in honour of Queen Elizabeth, it is stated that there was "a notable consort of six Musitions," whose music so pleased the queen "that in grace and favour thereof, she gave a newe name unto one of their Pavans, made long since by Master *Thomas Morley*, then Organist of Paules Church." This statement, however, lacks corroboration, and if Morley ever held the post, he must have done so for a very short time. On 5th July 1588 he was admitted Mus. Bac. at Oxford. Four years later (24th July 1592) he entered the Chapel Royal, where he successively filled the offices of epistler and gospeller. From the dedication to his first book of canzonets it seems that in 1595 Morley was married. His wife's Christian name was Margaret, and before her marriage she apparently held some post in the household of Lady Periam, wife of the Lord Chief Baron of the Exchequer. On 11th September 1598 Morley received a licence for twenty-one years to print ruled music-paper and song-books in English, Latin, French, or Italian. His rights under this grant were assigned by him to various publishers. In Burgon's *Life of Gresham* it is stated (ii. 465) that the registers of St Helen's, Bishopsgate, show that Morley lived in that parish. This is inaccurate, and there is no proof that the family of the same name residing in St Helen's between 1594 and 1600 was related to the composer. In the preface to his *Plaine and Easie Introduction to Practicall Musicke* (1597), Morley gives as one of his reasons for undertaking that work that he led a solitary life, "being compelled to keepe at home," presumably

owing to ill-health. On 7th October 1602 his place in the Chapel Royal was filled up, and on 25th October 1603 administration of his goods was granted to his widow. This document (*Act Book*, 1603, fol. 171) describes him as "late parishioner of St Botolph's near Billingsgate," but the registers of that parish contain no entries relating to him. Morley was incontestably one of the greatest of the Elizabethan composers. His madrigals, canzonets, and ballets are as remarkable for their beauty as they are for their admirable workmanship, and his *Introduction to Practicall Musicke*, in spite of its frequent obscurity, is an invaluable source of information as to the state of musical science in England at the end of the 16th century. His works are: (1) *Canzonets to Three Voices* (1593, 2nd edition, 1606; 3rd edition, 1631; German Translations: Cassel, 1612, and Rostock, 1624); (2) *Madrigals to Four Voices* (1594, 2nd edition, 1600); (3) *First Book of Ballets to Five Voices* (1595. An Italian edition appeared in London in the same year, 2nd edition, 1600; German edition, Nuremberg, 1609); (4) *First Book of Canzonets to Two Voices* (1595; 2nd edition, 1619); (5) *Canzonets or Short Little Songs to Four Voices, selected out of Italian Authors* (1597); (6) *Canzonets to Five and Six Voices* (1597); (7) *A Platine and Easie Introduction to Practicall Musicke* (1597; 2nd edition, 1608; 3rd edition, 1771); (7) *Madrigals to Five Voices, selected out of Italian Authors* (1598); (8) *The First Book of Consort Lessons, made by divers authors, &c.* (1599; 2nd edition, 1611); (9) *The First Book of Aires to Sing and Play to the Lute with the Base Viol* (1600); (10) *The Triumphs of Oriana to Five and Six Voices, composed by divers several authors* (1601). Besides the above, services, anthems, motets, and virginal pieces by Morley are to be found in various collections, both printed and manuscript.

(w. B. S*.)

Mormon Church.—The most conspicuous events in the history of the Church of Jesus Christ of Latter-day Saints (*i.e.*, the "Mormon" Church) since 1880 concern polygamy. The Morrill Act of 1862 for the suppression of polygamy in the territories was inoperative owing to certain defects in the law, which made conviction uncertain, and to lack of strong public demand for its enforcement. From time to time other laws of increasing stringency were enacted to the same end. These measures were finally amended and supplemented by the Edmunds-Tucker Act of March 1887, which became a law without the President's signature. By it polygamy and cohabitation with more than one woman as wife were prohibited; persons were disfranchised who could not, or would not, swear that they were guiltless of these offences; woman suffrage, permitted in Utah by Act of Legislature in 1870, was forbidden; the Mormon Church and the Perpetual Emigration Fund Company were disincorporated; the property of these organizations was declared forfeited to the Federal Government, the proceeds to be devoted to the public schools—property actually in use for worship and similar purposes being exempt. Vigorous prosecutions of offenders were at once instituted. The Mormons were at great expense in attacking the validity of the Act, but its constitutionality was sustained by both state and federal supreme courts. Many of the most notable polygamists and eminent authorities of the Church escaped prosecution by hiding—in local slang, by "going on the underground." The property confiscated in the territory of Utah amounted in value to about \$1,000,000. The legislature of the territory of Idaho also struck at polygamy in 1885 by the "Test Oath Act," which disfranchised all persons belonging to any organization that should teach or encourage polygamy or unlawful cohabitation. A similar law was for a short

time in force in Arizona. In July 1887, John Taylor, president of the Mormon Church, died while in concealment in a small town near Salt Lake City, Utah. The apostles administered the affairs of the Church until April 1889, when Wilford Woodruff, the senior apostle, succeeded to the presidency. The rigid enforcement of the law did at last what the Acts designed to accomplish. On 24th September 1890 President Woodruff issued the famous manifesto in which he said: "Inasmuch as laws have been enacted by Congress forbidding plural marriages . . . I hereby declare my intention to submit to those laws, and to use my influence with the members of the Church over which I preside to have them do likewise . . . and I now publicly declare that my advice to Latter-day Saints is to refrain from contracting any marriage forbidden by the law of the land." On the 6th of October following, the general conference of the Church approved the manifesto, and by resolution asserted that "we accept his declaration concerning plural marriage as authoritative and binding." These utterances were accepted as made in good faith, and prosecutions at once ceased. Most of the polygamists desisted from cohabiting with their plural wives, and, excepting a few cases, apparently not sanctioned by the Church authorities, no further polygamous marriages have since then taken place. Between 1852, when the doctrine of polygamy was first openly promulgated, and 1890, about 10 per cent. of the adult male members of the Mormon Church took plural wives, practically every man occupying a position of eminence or authority being a polygamist. In all, about 1200 persons were convicted of polygamy or unlawful cohabitation in the territories of Utah, Idaho, and Arizona. The usual penalty was a fine of \$300 and confinement in the penitentiary for six months. Under the "test oaths" nearly 12,000 were disfranchised. On the 4th of January 1893, in response to a petition from the officials of the Church, pledging the membership thereof to faithful obedience to the laws against polygamy, &c., and begging amnesty, the President of the United States, Benjamin Harrison, issued a general pardon to all liable to the penalties of the Edmunds-Tucker Act, who had abstained from offending since the 1st of November 1890. On the 25th of September 1894 President Cleveland also granted full amnesty to all who were under political disability for violating the anti-polygamy laws, and who had been law-abiding since the 1st of November 1890. One of the conditions on which Utah was admitted to statehood in 1896 was that polygamy should be prohibited by an article in the state constitution, repealable only with the consent of the United States and of the people of the state. Although the practice of polygamy has been suspended by the Mormon Church, the doctrine is still a valid one. That polygamous relations were not entirely abandoned by individual Mormons is shown by a few convictions since 1890, and in the passing of an Act by the first state legislature in 1896 legitimizing all children born of plural wives previous to the 1st of January 1896. In March 1896 the escheated property of the Church still in possession of the United States Government, amounting to \$285,000, was restored. About \$450,000 in the aggregate had been previously restored in instalments. The remainder had been consumed in fees and other expenses of managing. The Emigration Fund Company was never reorganized. The Church as a whole was not again incorporated, its legal business being transacted by its president as "Trustee-in-trust for the body of religious worshippers known as the Church of Jesus Christ of Latter-day Saints." Each "ward," or administrative unit, has been incorporated, its executive head being known as "bishop."

On the 6th of April 1893 the Mormon temple in Salt Lake City was completed and dedicated. Work on this building had been in almost continuous progress for forty

years. The cost was approximately \$3,000,000. There are three other temples in Utah, in Logan, Manti, and St George respectively, which though costly are smaller and less elaborate. These edifices are not used for public assemblies of any kind, but are arranged for the secret performance of the sacred rites of baptism, of marriage, of baptism in behalf of dead ancestors and friends, and of "endowment," or the higher ordinances of the Church.

President Woodruff died in 1898, and was succeeded in office by Lorenzo Snow. President Snow died in October 1901, and was succeeded by Joseph F. Smith, nephew of Joseph Smith, the founder of the Church. Missionary activity has always been one of the most important policies of the Church. Most of the male members are expected to spend a season away from home preaching the tenets of the Mormon faith. Two years is the usual term. Missionaries to foreign countries, who must learn a new language, often remain three years or even longer. Zealous and efficient men frequently serve more than one term. These missionaries are usually young men, who pay their own expenses, even buying the tracts, pamphlets, and books they distribute. In 1901 nearly 2000 Mormons were in the mission field, a few of whom were women. Formerly a person when "called" must go, regardless of financial or family considerations. The system is maintained partly to gain converts and partly as a discipline to the missionaries. At the beginning of the 20th century the growth of the Church through converts did not seem so great, proportionally, as at some previous times. The missionary work is thoroughly systematized. There are fourteen organized "missions," viz., the Eastern States (United States), the Northern States, the Southern States, the South-western States, California, Great Britain, Switzerland, Germany, the Scandinavian countries, Hawaii, Australia, New Zealand, and Samoa. In 1901 Japan was added. Until about 1892 most converts from nearly all parts of the world, the Pacific Islands being the chief exception, emigrated to Utah or adjacent states and territories, where work and an opportunity to make comfortable homes were provided. Since then the policy, in general, has been to encourage converts to remain at home and so form centres for spreading the influence of Mormonism and for lessening the difficulties of missionaries in their travelling work. Emigration has been greatly assisted by the Perpetual Emigration Fund Company. This society, organized in 1849, incorporated in 1851, and dissolved in 1887, provided means, in whole or in part, to indigent converts for transportation to Utah, the aid being regarded as a loan to be repaid whenever the assisted immigrant should become financially able. Over 50,000 persons have received benefits from the company.

The looked-for Zion of the Mormons, where the final "gathering" shall be, is not Utah but western Missouri, the city of Independence being regarded as the centre. The principal administrative divisions of Mormondom, where the Church is fully organized, are known as "Stakes of Zion," the figurative name being suggested by the stakes that hold a tent firm. There are about fifty of these "stakes" in the western part of the United States, in Alberta, Canada, and in Mexico. In 1901 the Church had about 300,000 members, of whom 200,000 lived in Utah, where they constituted about three-fourths of the entire population of the state; 60,000 were found in neighbouring states, and 40,000 were distributed in other parts of America, and in Europe and the Pacific Islands. Public schools, although early established in the Mormon settlements of Utah, were slow of development. In 1888 President Woodruff began active measures to institute Church schools. In a few years a well-organized system

was in operation, under control of the general Church board of education. Many of the "stakes" support academies, which when completely developed will conduct full high school courses. Three institutions, the Brigham Young Academy at Provo, the Brigham Young College at Logan, and the Latter-day Saints' University at Salt Lake City (until 1901 known as the L. D. S. College), attempt college work and offer degrees. These were founded prior to 1888, but were put under the control of the general board. In some communities where the Mormons are in considerable majority these Church academies supply the place of public high schools.

The industrial policy of Mormons is summed up in the word "co-operation." It was the aim of the early leaders in Utah to make their people self-reliant and independent of non-Mormons. The virtue of mutual helpfulness was therefore inculcated. Companies of settlers were sent to the richest valleys of the inter-mountain region wherever the soil could be most easily irrigated. Each company was selected with care to include artisans of all the indispensable crafts, and the people, closely bound by common ties, lived like members of a family. They enclosed great tracts of land for the use of the community, appropriated the water of convenient streams, and exchanged products and labour. President Young tried to provide that each family in towns should own at least an acre, and each family in farming districts fifteen or twenty acres. He believed that a comparatively small estate well cultivated was better than a large farm badly cared for. People were taught to shun debt, and mortgages were almost unknown. The result of this was shown in 1900, when 60 per cent. of the families in towns and cities lived in their own homes, and 91 per cent. of the farmers tilled their own soil. On their arrival, Mormon immigrants were made up into new companies for settlement, or were distributed among the older places according to the needs of the several communities. Men of almost every skilled trade were found among the early inhabitants of Utah. In caring for the poor the Church was a vast labour exchange, and kept in touch with the industrial necessities of every locality, and wherever men needed work or work needed men, the want was supplied. Home production of everything requisite was encouraged by President Young, and under his influence a great variety of industries was fostered. The building of a railway through Utah in 1869 made possible the competition of cheaper and better goods from the East, and many promising enterprises perished. For twenty years after the settlement of Utah, barter was the chief means of exchange, and, as it permitted readier local transactions and compelled the Mormons to be less dependent on Gentiles (*i.e.*, non-Mormons), the system was encouraged long after it might have been supplanted by a more extensive use of money. The existence of precious metals was early discovered in Utah. But fearful that a mining mania would result in utter neglect of farming, with consequent distress, if not famine and starvation, Mormons were practically forbidden to open mines. Mining was therefore developed almost wholly by Gentiles, and for many years was carried on by them.

Until three years after the Mormons reached Utah there were no shops in the territory. The most flourishing stores were first conducted in Salt Lake City by Gentiles, who, possessing capital and credit, had a monopoly and practised extortion. These merchants did nothing for the improvement of the town, and spent their money elsewhere. This eventually led to the establishing of co-operative companies in nearly every settlement, the shares of which were widely distributed in small lots among great numbers of holders in the different communities. The prices of goods were made reasonable, and all profits

beyond a certain percentage were devoted to the erection of new and substantial store buildings and to other enterprises, which gave work to the people and tended to improve the towns. The Church authorities used their utmost power to further these concerns. At one time there existed no fewer than 200 of them, but they gradually grew less popular, and individual firms and merchants, not always Mormon, opened businesses, and by 1880 controlled the bulk of the trade. Some of the co-operative shops closed. Others consolidated, until in 1900 they did not exceed 60. The shares, too, generally gravitated into the hands of comparatively few, and were even sold to Gentiles. The co-operative establishments conducted business on such conservative lines and with such punctilious regard for all obligations that no concerns in the country enjoyed higher credit in the commercial world. The most successful of these establishments is the Zion's Co-operative Mercantile Institution in Salt Lake City, organized in 1868, incorporated in 1870 for twenty-five years, and reincorporated in 1895 for fifty years. The original capital was \$220,000, which has been increased to \$1,077,000, partly by stock dividends representing cash accumulations. From the date of its founding to June 1901 it has paid over \$2,550,000 in dividends. The net transactions amount to \$4,000,000 per year. Besides maintaining mercantile departments in which nearly every commodity is sold, the company engages in the manufacture of shoes and of clothing. It has branches in Provo and Ogden, Utah, and Idaho Falls, Idaho. Its stockholders number 600.

With the opening of many rich mines and the building of railways, isolation has become no longer possible. Population has rapidly increased, and life has grown more complex, and whatever was socially or economically distinctive among Mormons has slowly disappeared.

(G. M. M.)

Morocco (EL MAGHRIB EL AKSA, "The Farthest West," *i. e.*, of the Mahomedan world), bounded on the N. by the Mediterranean, on the E. by Algeria, on the S. (indefinitely) by the Sahara, and on the W. by the Atlantic as far south as Wad Draa. It is the only North African state retaining its independence, and therefore presents peculiarly interesting features. The climate is good, and produces a hardy race. Shielded by the Atlas from the hot winds of the Sahara, the coast of the Atlantic offers great attractions to those suffering from chest complaints. Tangier is already a recognized health-resort, and Mogador and Rabat await development as such. Rain falls only between September and April; on the Atlantic coast it is brought by the south-west wind, and on the Mediterranean sometimes also by the east wind, or *sharki*, otherwise dry and somewhat trying to invalids. The wonderfully temperate climate of Mogador is due in a great measure to trustworthy trade-winds. In Tangier and Mogador the summer heat is rarely oppressive, never injurious, as the thermometer seldom rises over 80° F. or sinks below 40°, although inland the extremes are much greater; and while on the plains or in low-lying cities the heat grows intense, snow gleams on the Atlas all the year round.

Three races inhabit Morocco, and members of two others are continually introduced. The aboriginal Berbers occupy the mountainous districts, where they still maintain a degree of independence. The plains are for the most part occupied by Arabs, introduced in the 11th and 12th centuries, or by the mixed race to which the majority of the dwellers in towns belong, called by foreigners "Moors" from the old Latin "Mauri." The third race is the Jewish, of which the original stock dwells inland, speaking Arabic and Berber, the majority of the more

modern arrivals, expelled from Europe, having remained in the ports, where they still speak Spanish. The slave trade with the western Sudan maintains a small proportion of negroes, intermarriage with whom has produced bronzed types, for both Berbers and Arabs are white-skinned. On the coast there are small colonies of Europeans, chiefly engaged in trade. The largest of these colonies, principally Spanish, is found in Tangier. The most widely spoken language is Berber, varying in dialect, but the language of the Government and creed is Arabic, for the religion of the empire is Islám, the Moors being among the strictest followers of Mahommed. The divisions of the East are unknown, and their tenets include the principal teachings of both Shias and Sunnis, but, as employing the Máleki ritual, they must be classed with the latter. Recognizing their own Sultan as Amir el Mû'minín (Commander of the Faithful) and Khalifa of God on earth, they acknowledge no other claimant, and have few dealings with the Turks, whom they consider corrupt. They have not yet given way extensively to strong drink, and the use of tobacco is also frowned upon and forbidden by law. The Moors are bigoted even when friendly.

Population.—The number of the population has never been known, and while so large a portion of the empire remains unexplored, statistics must be represented by conjecture. Estimates in this case vary from five to ten millions, the majority of whom are pastoral and agricultural. There are only three great inland cities, each of which in turn serves as metropolis—Fez, Mequinez, and Marrákesh. The towns next in importance are the seaports of Tangier, Mogador, Casablanca (Dar el Baida), Azammûr, Mazagan, Saffi, Salli-Rabat, Laraiche, and Tetuan. On the Mediterranean shore, along the coast of Er-Rif, the Spaniards have for centuries possessed Ceuta, Peñon de Velez, Alhucemas, and Melilla; in 1848 they appropriated the Zaffarine Islands. Inland the only other important cities are the sacred towns of Zarhôn, Shesháwan, and Wazzán (the last-named of which alone is open to Europeans), and the minor towns of El Kasar, Sifrû, Taza, Dibdû, and Oojda in northern Morocco (once the kingdom of Fez); Damnát, El Klá, Sidi Rahal, Zettát, and Amzmiz in central Morocco (once the kingdom of Marrákesh); Tarudant, Agadí Ighír, Iligh, Tiznit, and Glímín in southern Morocco (once the kingdom of Sûs), and the districts of Tafilált and other Saharan oases beyond the Atlas.

History.—The history of the Moorish empire commences with the settlement near the Roman ruins of Volubilis in A.D. 788 of Idrees the elder, one of the fugitive descendants of Mahommed, during the struggles between rival claimants of the khalifate. Islám had then been established in these parts for eighty years, but Idrees and his son, Idrees II., the builder of Fez, extended its influence, uniting the Berbers into a kingdom. Their line controlled a limited portion of northern Morocco for nearly two centuries, in part supplanted by the Miknásà in 917, until displaced by the Magháwà in 988. These two dynasties were exterminated in 1067 by Yüsef I. (bin Tashfin), founder of the Murábtí ("Almoravide") dynasty of Berbers, who added the remainder of Morocco, most of Spain and Portugal, and Tlemçen. In 1147 their power was overthrown by a religious leader, 'Abd el Mû'min, at the head of the Muwáhhadi—*i. e.*, Unitarian—horde ("Almohades"), under whom the Moorish empire reached its zenith at the close of the 12th century. It then included, in addition to the Murábtí realm, what now are Algeria, Tunisia, and Tripoli, extending to the frontier of Egypt, which they were prevented from occupying by the rise of Saladin. Before the middle of

the 13th century they had been driven out of Spain, and had lost all but what is now known as Morocco, whence, between 1217 and 1269, they were ousted by the Beni Marin ("Marinides"). These retained nominal power for three hundred years, but during their third century they became so enfeebled that all continuous record is lost. A branch of the same family, known as the Watási, reigned in northern Morocco (kingdom of Fez) from 1471 to 1548, when the whole country passed into the hands of the Sa'adi Shereefs, who had occupied southern Morocco (kingdom of Marrákesh) since 1521. Their rule lasted but a century, for between 1630 and 1668 they were gradually replaced by another family of Shereefs, the Filáli, which is the ninth and reigning dynasty. Of this line the Sultan reigning in 1902—Mulai ("my lord") 'Abdul 'Aziz IV.—was the fourteenth. He succeeded his father, El Hasan III., in 1894, at the age of fourteen, the empire being governed for the first seven years by a regent. His Shereefian Majesty, or The Lofty Portal ("Sublime Porte"), as he is officially styled by Europeans and natives respectively, is married and has sons.

An excellent sketch of the Sultan Mulai 'Abdul 'Aziz and of his court was given in *The Times* of 10th June 1901, by a correspondent who wrote from Tangier on 12th May, *à propos* of the special embassy which was being sent to congratulate King Edward VII. on his accession to the throne. We give the following extract from that article:—

The Sultan and his court.

"Mulai Abdul Aziz succeeded to the throne on the death of his father, the late Sultan Mulai Hasan, in 1894. At the time of his father's death young Abdul Aziz was in Rabat with his mother, a Circassian lady, and it was there that he was proclaimed. Mulai Hasan died during a punitive expedition in the central provinces of his country; but, owing to the extraordinary capability of Si Ahmed Ben Musa, the chamberlain, his Shereefian Majesty's death was concealed from the world, and for two days even the palanquin-bearers imagined that they were carrying a living, though ill, Sultan, and never suspected that their burden was a corpse. Two days were sufficient for the wily chamberlain. It gave him time to proclaim young Abdul Aziz in Rabat, and to lay the foundations of his plans by which he afterwards became Vizier and practically Sultan, while the real holder of the title was kept hidden away in the palace. But Mulai Abdul Aziz had an elder brother, Mulai Mohammed, who had been Viceroy of the South, and who by his generosity—with other people's money—and by his libertine ways was extremely popular with the general public. A rising in his favour occurred, but the iron will of the Vizier Si Ahmed crushed it, and even to-day (1901) the prisons are full of the tribesmen who rose, while Mulai Mohammed himself lives in confinement in Mekinez. The Vizier died in 1900, still in possession of his great influence, and leaving to be confiscated by his royal master a huge fortune, amounting, it is said, to some millions sterling, every penny of which had been squeezed and extorted from the wretched population of the country. His death gave Mulai Abdul Aziz, then some nineteen years of age, an opportunity of emerging from his almost enforced seclusion and of exercising his authority, for up till this period his identity had been entirely overshadowed by that of his powerful and cruel Vizier. Since the death of Si Ahmed he has certainly come forward, and the northern blood inherited from his Circassian mother has rendered him not a little susceptible to European influence, though possibly not to his own advantage. The Moorish Sultanate is so essentially a religious one, depending upon that descent from the Prophet which confers the title of Amir el-Mumenin—Commander of the Faithful—that any change in the régime of the court would at once raise the antagonism of the large and fanatical religious faction. At present these progressive tendencies have done little more than interest his Shereefian Majesty in European inventions. He rides a bicycle, photographs, and enjoys the cinematograph. So lavish has he been in obtaining all the newest inventions and toys of Europe that one trading Jew alone, who brought him a real circus to the capital, has received some £20,000 of the country's revenue, drawn from the custom-house of Mazagan. It is the custom, unfortunately, for Oriental monarchs to hoard their private fortunes and to draw upon the resources of their country for their private amusements. In appearance Mulai Abdul Aziz is tall and well-built. In bearing he is very dignified. On public occasions, in his loose white

robes, he looks, and is, a Sultan. His life is one of great simplicity. He rises at dawn and prays at the regular stated intervals throughout the day. His food is simple, and eaten, according to the custom of his country, without knife and fork.

"The position of a Sultan of Morocco never allows him to come into actual touch with his subjects, and the principal power therefore rests with the Grand Vizier. The present (1901) holder of this important office, though he prefers to call himself the Minister of War, is a young and energetic man, Kaid Mehedi el Menebhi, who was in former days an understudy of Si Ahmed. His influence is all-powerful, and it was through his agency that, in April 1901, the elderly Haj Mukhtar, the nominal Grand Vizier, a refined and honest old man, who had done all in his power not to be appointed, was sent a prisoner to Fez, while all his property was confiscated. He knew a year before, when he received his appointment, what his fate would be. Such falls from power are of everyday occurrence in Morocco. No man knows his fate until the fatal day arrives, and the writer has been the guest of a great local governor, whose stables were full of splendid horses, and who was served by a horde of attendants and servants—and within a month he has given in charity a loaf of bread to the same governor's son, begging in the streets, while the father lay dying in prison. The son of another great official, whose wedding attracted thousands of tribesmen, and whose generosity was unsurpassed, was met by the writer within a year loading the baggage mules of a European envoy amongst the muleteers of the Sultan's army. No complaint, no despondency—merely the recognition that the wheel of fortune had turned!

"It is a picturesque court, that of the Sultan of Morocco. The great palace squares and courtyards, topped with the iridescent green-tiled roofs, the miles of fortified gardens, the high windowless walls, all present an appearance of unfathomable mystery. Seldom, indeed, do men penetrate within, for the precincts are sacred to the rule of women. Even the ministers of the Great Powers, on their periodical embassies to the Moorish court, see little more than the outside walls and the great green gates. At private audiences with the Sultan the visitor is led through tangled vine-clad gardens to some little summer-house, rich in exquisite plaster-work and tiles, half-ruined, perhaps, and yet a gem, where, under a ceiling gorgeous in colours and gilding, sits the almost pathetic figure of the Sultan. The Grand Vizier stands by his master's side, and without the doorway, out of sight of their sovereign, are seated half a dozen soldiers awaiting orders. And all around the tall dark cypresses shoot up their pillar-like forms. Very different is the public reception of the accredited ministers of Europe—very different and more humiliating. The Sultan is mounted, seated on horseback under his umbrella of state, surrounded by his courtiers and preceded by his officers of state. His led horses champ their bits and wave their marvellous manes and tails, and the sun glitters on the lances of the spear-bearers and the gold-embroidered saddles. The empty green-and-gold brougham, part of all processions, creaks and groans as it is brought into position, and in front of it all, bare-headed in the bright sunshine, and on foot, stand the envoys of the emperors and kings of Europe. A blare of trumpets, a banging of salutes, and the Sultan and his procession disappear through the great palace gates, and the reception, as picturesque as it is humiliating, is over.

"The Sultans of Morocco usually divide their time between their southern and northern capitals, Marrakesh and Fez respectively. They are great undertakings, these flittings of Sultans, for, with their army, their court, and their hangers-on, the imperial party often numbers some 30,000 or 40,000 persons. His Shereefian Majesty's progresses through the country leave poverty, destitution, and famine behind them, for, like locusts, they eat up everything. The one hope for Morocco lies in its young Sultan. He has already shown signs of a desire for the improvement of his country."

Government.—The Moorish government is a limited autocracy, the theoretical power of the sultan or emperor being greatly circumscribed by the religious influences which in a measure support him, and by the unpaid official proletariat with which he is surrounded, whose intrigues, in conjunction with those of European Powers, effectually check all progress. There is no regular assessment for taxation, but such organized spoliation as may be required for public or private ends. Centring in a group of wazeers, the administration radiates through despotic local governors to sheikhs and an unpaid police.

Army.—A half-organized army, service in which is partly hereditary, partly forced, is periodically employed in collecting taxes at sword-point, and in "eating up" the provinces; with it the Sultan goes forth to war each summer, spending the winter

in one of his capitals. He has no army adequately trained for effective defence, and the "Armstrongs" at Tangier and "Krupps" at Rabat are useless by themselves. The only approach to a regular army consists of certain hereditary troops, the Bokhára (black), the Udáia (mulatto), the Ashragah and Ashrárdah (white), and the Gaish, who form a body of police, Makhházná (mixed), all of whom are horsemen. The infantry (Askária) are mostly rough, ill-trained levies, summoned each year for military expeditions against recalcitrant tribes; they are of varying numbers, only a small portion being well trained under an English instructor and French and Italian military missions. No accurate estimate can be formed of the total available forces, and the arms are of every pattern. There is no navy.

In these circumstances it is surprising to find that foreigners enjoy protection and liberty wherever the Sultan's writs run, that is to say, on the plains, but it is still more surprising to find that by treaties of long standing they are enabled to secure protection for natives having charge of their interests, without which trade would be impossible. The desire for this protection from rapacity induces the natives to offer premiums for such employment, and this in its turn leads to abuses unavoidable without further regulation, although much has been done towards this end since the Madrid Convention which met in 1881 for the purpose of discussing this question. Foreigners leaving the beaten tracks (there are no roads) are required to employ a policeman (*makházni*) to guard their persons and to prevent their attempting exploration. All their Powers are represented in Tangier by diplomatic and consular officials, who exercise independent jurisdiction over their respective fellow-subjects, to the frequent confusion of justice. The evidence of non-Mahomedans is not accepted in Moorish courts, where venality reigns, and unprotected Jews suffer constant injustice, besides daily indignities, for which they repay themselves by superior astuteness.

Education.—The level of education could hardly be lower, although most males have an opportunity of learning at least to recite or read the Koran, if not to write. Only traders trouble about arithmetic. Youths who desire to pursue their studies attend colleges in Fez or elsewhere to acquire some knowledge of Mahomedan theology, logic, composition, and jurisprudence, beyond which information is considered superfluous. The intellectual accomplishments of the Moors of the Middle Ages have been greatly over-estimated. The stars of their brightest period in Spain were Jews or Spaniards, who were sometimes persecuted for attainments which have, by strange perversion, shed a lustre on their persecutors, to whose creed they only adhered by compulsion. The social condition of Morocco is that of all Mahomedan countries unaffected by the influences of Christendom, such as Upper Egypt, Central Asia, and Arabia, but even in Morocco it is becoming corrupted rather than improved by intercourse with Europeans on the coast.

Produce.—The natural products remain almost entirely undeveloped. Numerous attempts have been made of late years to obtain concessions for mining and other exploitation, but in all the Government sees further complications with Europe: if, by wholesale bribery, any grant is obtained, a nullifying clause is inserted, or the first occasion is seized to raise anew insuperable obstacles. Agriculture, being in native hands, is less restricted, but so many difficulties are placed in the way of exportation, that the most prolific cereals are raised in quantities hardly exceeding the local demand, and falling short of it in years of drought. Periodical famines are the result. The breeding of horses or cattle, and the rearing of birds for European markets, suffer in the same way, but increase in spite of restriction and heavy dues. One of the most promising developments of recent years has been the growing supply of chickens, eggs, and fruit to Europe, even to England. The fisheries also are capable of great expansion, and are at present almost entirely in the hands of Portuguese and Spaniards.

Manufactures.—The manufactures are few, and the most famous—leather—is now either exported undressed to Marseilles or Philadelphia, or is counterfeited by machinery in London or Paris. With the exception of a few slippers and shawls supplied to Moors established in the Levant, its manufactured exports consist principally of carpets, rugs, trays, arms, and "curios" for decorative purposes. For home use the Moors do much spinning, weaving, and dyeing, chiefly of wool; but although it is possible to dress superbly in native-made articles, every year sees an increasing importation of Manchester and Yorkshire goods, rivalled by the cheaper products of Barcelona and Austria, in the last case with great success. Next to "cottons," the import upon which most duty is paid is green tea, transhipped in London; then come sugar of French, Belgian, or English manufacture, and candles from the same sources. Hardware follows, but machinery holds a very low place.

Commerce.—The commerce is almost entirely shared thus: Great Britain, one-half; France, one-quarter; Germany and Austria, one-tenth; and Spain, one-twentieth. The fluctuation in its

volume is so slight that it may almost be regarded as stationary. Everything depends upon the state of the crops, and this in turn depends upon the rainfall, but even a good year is sometimes to a great extent wasted by internal dissensions. The average annual export trade of the empire may be reckoned at rather under £1,000,000 sterling, and the average import trade as rather over that sum, the figures having stood in 1873, with phenomenal crops, at £1,553,446 and £934,478 respectively, and at an average during succeeding years of about £900,000 and £1,000,000 respectively. At the same time, in the absence of adequate banking facilities, the amount of specie exported and imported ranges out of all proportion to the difference between these figures, and the constant variations in exchange and currency are serious impediments. But none of the figures supplied can be regarded as more than approximate, by reason of the meagreness and imperfection of the records available, and the constant evasion of customs dues by bribery and false invoices—not to mention ordinary smuggling—so that the actual bulk of the trade is greater than it here appears. The following are the official returns of exports and imports for the year 1900:—

Ports.	Exports.	Imports.	Totals.
Tangier	£386,274	£481,356	£867,630
Tetuan	4,360	33,586	37,946
Laraiche	47,033	114,693	161,726
Rabat	20,071	95,440	115,511
Dar el Baida	307,730	291,289	689,019
Mazagan	360,577	281,690	642,267
Saffi	143,438	83,073	226,511
Mogador	407,592	246,231	653,823
Total	£1,767,075	£1,627,358	£3,394,433
Share of Great Britain	£534,478	£888,251	£1,422,729

Communication.—The facilities for communication with the outside world have become greatly extended. Regular and more frequent steamship services now link Morocco with London, Antwerp, Hamburg, Lisbon, Cadiz, Gibraltar, Malaga, Barcelona, Marseilles, Genoa, Oran, Malta, Alexandria, the Canaries and Madeira, Rio Janeiro and Montevideo, and, by transhipment at Gibraltar—only three hours from Tangier—with all great ports, East and West. The tourist traffic in particular has grown exceedingly, but shows itself still in its infancy. Great Britain, Spain, France, and Germany have postal agencies, and run competing courier mails along the coast, while Great Britain and Spain have laid telegraphic cables from Gibraltar and Tarifa respectively to Tangier; but the extension of wires inland, save for telephones and electric light, is still prohibited. At the same time the means of internal communication remain unimproved. Travelling in the interior is what it was a thousand years ago. Several courier services have indeed been established to inland towns, but rather as a speculation in postage stamp issues than for public benefit, though some have now been taken over by foreign postal authorities.

Finance.—Banking is rarely resorted to, except in underground hoards, though a few enlightened natives know the value of British Consols, and the local Jews continue to transact financial operations with convenience to their clients and considerable satisfaction to themselves, in the manipulation of the exchange and the calling in or pouring out of debased Spanish coinage. One innovation has been the repeated issue of a Moorish coinage of corresponding denominations, minted in France and Germany, and the introduction on the coast of Spanish copper. Moorish weights and measures continue to vary from town to town, but in the foreign trade the decimal system has almost entirely superseded the native chaos. Credit is allowed by European houses at their peril, and in some lines profits are cut ruinously fine or done away with altogether by dishonest practices, many arising out of the long credit in vogue.

Missions.—The most striking sign of the times in Morocco has been the almost concurrent though independent introduction of the press and evangelical missions. The Franciscans had for six and a half centuries done brave work in the country, since the founder of their order offered himself for that task in 1214, and many of them, including several British and Irish missionaries, had suffered martyrdom, but they have long abandoned attempts to convert the Moors. The London Jewish Society was established in Mogador in 1875, and since 1883 various Protestant agencies have commenced operations, and now support between them some ninety missionaries, male and female, including doctors and nurses.

The Press.—Journalism is entirely foreign, and was introduced in 1883, at the same time as the printing-press, Spanish, French, and English newspapers being established in quick succession. These have done much to make the true state of Morocco known.

Attempts to establish Hebrew and Arabic papers have hitherto failed. The late Sultan even went so far as to set up a lithographic establishment in Fez, from which a valuable series of Arabic theological, legal, and historical works have been issued, but most noteworthy of all is the publication in Cairo in 1895 of an Arabic history of Morocco, in four volumes, by a native of Sallí, Ahmad bin Khalid en-Násiri. Other forward steps have been taken in the production of several important volumes on the country, and in serious attempts to explore the Atlas. The vicomte de Foucauld has attained the first place by his intrepid journeys as a Jew through the forbidden regions, and by his workmanlike geographical records; the late Joseph Thomson did good work in the Great Atlas, though within a limited area; the vicomte de la Martinière has excavated some of the Roman remains; and Mr Walter B. Harris made a bold journey to Tafílat. An equally important service was rendered by the compilation by Sir R. Lambert Playfair and Dr Robert Brown of an invaluable *Bibliography of Morocco* containing over 2000 entries.

AUTHORITIES.—Besides the works named in the ninth edition, the principal contributions to the history are:—**Native:**—IBN 'ABD EL HÁKIM, embracing the period from A. D. 690 to 750 (tr. JONES). Göttingen, 1858.—'ABD EL WÁHID EL MARRÁKESHÍ (1149–1224), tr. E. FAGNAN in the *Revue Africaine*, 202–7. 1891.—*Raôd el Kartás* (788–1326), tr. BAUMIER. Paris, 1860.—EL MAKKÁRI (710–1500), tr. GAYANGOS. London, 1840.—EL UFRÁNI (1631–1812), tr. HOUDAS. Paris, 1889; and EN-NÁSIRI, not yet translated (710–1894). Cairo, 1895.—**Foreign:**—MOUËTTE. *Histoire des Conquestes de Mouley Archy*, &c. Paris, 1683.—DE EL PUERTO. *Mission Historial de Marruecos*. Seville, 1708.—BUSNOT. *Histoire du Regne de Muley Ismaïl*. Rouen, 1714.—MAS LATRIE. *Traité de Paix*, &c., 3 vols. Paris, 1866–72; and *Relations et Commerce de l'Afrique Septentrionale*. Paris, 1886.—MERCIEUR. *Histoire de l'Afrique Septentrionale*, 3 vols. Paris, 1888–91.—MEAKIN, BUDGETT. *The Moorish Empire, a Historical Epitome*, London, 1899, which contains critical notices of all important books on Morocco. **Geography:**—LEO AFRICANUS. *Della Descrizione dell' Africa*. Venice, 1526; tr. JOHN PORY, London, 1600; ed. Dr ROBERT BROWN for the Hakluyt Society, 1896.—MARMOL CARVAJAL. *Descripcion General de Africa*. Granada, 1573.—URRESTAZU, F. DE A. DE. *Viajes por Marruecos*. Madrid, 1877.—BONELLI, Captain E. *El Imperio de Marruecos*. Madrid, 1882.—DE CUEVAS, TH. *Estudio . . . de Laraiçhe*. Madrid, 1884.—ERCKMANN, Captain. *Le Maroc Moderne*. English translation of the former by J. MACIVER MACLEOD. Tangier, 1900.—MEAKIN, BUDGETT. *An Introduction to the Arabic of Morocco* (Vocabulary, &c.). Tangier, 1890.—BALDWIN, Miss C. W. *Morocco-Arabic Dialogues*. Tangier, 1892. (B. M*.)

Morocco City, the name sometimes erroneously applied to MARRÁKESH (*q.v.*).

Moron, a village in the province of Puerto Principe, Cuba, near the north coast, 250 miles east-south-east of Havana. It was noted as the terminus of one of the defensive *trochas* of the Spanish generals. Population (1899), 2084.

Morphy, Paul Charles (1837–1884), American chess champion, was born at New Orleans in 1837, and his skill in chess attracted attention while he was still a boy. In 1857 at the New York Chess Congress he defeated the leading amateurs, and in 1858 gave an exhibition of blindfold playing. He showed his skill in London, Birmingham, and Paris, and defeated the greatest masters of the day, remaining abroad for this purpose till 1859. He then returned to the United States and took up the legal profession; but he had put too great a strain upon himself, and besides having to give up

chess, his mental condition was permanently impaired, and he died without fulfilling his early promise in 1884. Morphy's name, however, became a household word as the first, and perhaps greatest, of the modern feat-performing chess champions.

Morrill, Justin Smith (1810–1898), American financier, was born at Strafford, Vt., on the 14th of April 1810. After a common school education and a business career, he was elected to Congress as an anti-slavery Whig in 1855. Becoming a Republican, he remained in the House of Representatives till 1867, and was then elected to the Senate, where he represented Vermont till his death on 28th December 1898, thus fulfilling the longest continuous service in Congress since the foundation of the government. His career was that of a hard-working and useful, rather than a brilliant member. His special interest lay in the field of industry and finance. The tariff of 1861 was largely his work and took his name, and all subsequent tariff and fiscal legislation was impressed with the influence he exerted as a member, in the House, of the Committee on Ways and Means, and in the Senate, as member and for a time chairman of the Committee on Finance.

Morris, a city of Illinois, U.S.A., capital of Grundy county, on the north bank of the Illinois river, and on the Chicago, Rock Island, and Pacific railway, in the north-eastern part of the state, at an altitude of 518 feet. It is in a coal-mining region, has varied manufactures, and is a shipping point for grain. Population (1890), 3653; (1900), 4273.

Morris, Sir Lewis (1833—), British poet, eldest son of Lewis Edward William Morris and Sophia, daughter of John Hughes of Carmarthen, was born at his father's house, Penbryn, in 1833. He was educated at Sherborne School and Jesus College, Oxford, where he took a first class in Moderations in 1853, and a first in *Literæ Humaniores* in 1855. He won the Chancellor's prize for an English essay in 1858, was called to the bar in 1861, and elected hon. fellow of his old college in 1877. He practised for twenty years as a conveyancing counsel, retiring from active legal work in 1881. He was energetic on behalf of educational movements in Wales, and contested Welsh constituencies in the Liberal interest, but without success. Sir Lewis Morris was knighted in 1896, and became also a Jubilee-medallist and Knight of the Redeemer of Greece. Comparatively late in life, Sir Lewis Morris made his appearance as a writer of verse with three series of miscellaneous poems, called *Songs of Two Worlds*, published respectively in 1872, 1874, and 1875. These little volumes proved him to have a refined taste and a gentle metrical fluidity, which soon won for his work considerable popularity. In 1876 and 1877 he made an important venture with *The Epic of Hades*, an attempt to re-tell the stories of Hellenic mythology with a certain modern and allegorical setting. This work, though it is not without false sentiment and artistic infelicities, contains his best verse and has passages of force and effect. His later work follows much too closely upon the influence of Tennyson, from which he is never altogether free; but his earnest didacticism, genial optimism, and evident sincerity have given his work a thoroughly wholesome influence.

Morris, William (1834–1896), English poet and artist, third child and eldest son of William Morris and Emma Shelton, was born at Elm House, Walthamstow, 24th March 1834. His grandfather was a respected tradesman in Worcester, and his father, who was born in that town in 1797, came up to London in 1820, and

entered the office of a firm of discount brokers, in which he afterwards assumed a partnership, and married Emma Shelton, of a well-reputed Worcester family. They moved to Walthamstow shortly before the birth of the subject of this memoir. As a child William Morris, the poet, was delicate but studious. He learnt to read very early, and by the time he was four years old was familiar with most of the Waverley novels. When he was six the family moved to Woodford Hall, where new opportunities for an out-of-door life brought the boy health and vigour. He rode about Epping Forest, sometimes in a toy suit of armour, became a close observer of animal nature, and was able to recognize any bird upon the wing. At the same time he continued to read whatever came in his way, and was particularly attracted by the stories in the *Arabian Nights* and by the designs in Gerard's *Herbal*. It is not unlikely that the first seeds of later tastes were sown in these associations. He studied with his sisters' governess until he was nine, when he was sent to a school at Walthamstow. In his thirteenth year his father died, leaving the family well-to-do; the home at Woodford was broken up, as being unnecessarily large; and in 1848 William Morris went to Marlborough, where his father had bought him a nomination. Marlborough College was at that time in a state of considerable confusion, following upon an unmethodical start with numbers rapidly outgrowing accommodation. Discipline was relaxed, and games were disorganized. Morris was at the school three years, but got very little good from it, beyond a taste for architecture, fostered by the school library, and an attraction towards the Anglo-Catholic movement. He made but slow progress in school work, and at Christmas 1851 was removed and sent to a private tutor for a year. In June 1852 he matriculated at Exeter College, Oxford, but, owing to the college being full, did not go into residence till January 1853. Morris found Oxford in a state of mental and spiritual lethargy, and never acknowledged much advantage from its educational side. The typical "don" was always an object of dislike with him, and he thought the Oxford curriculum forced and lacking in expansiveness. But he at once made friends who stood him in good stead all his life, foremost among whom were Edward Burne-Jones, who was a freshman of his year, and a little Birmingham group at Pembroke. They read together theology, ecclesiastical history, mediæval poetry, and, among moderns, Tennyson and Ruskin. They studied art, and fostered the study in the long vacations by tours among the English churches and the Continental cathedrals. Moreover, Morris began at this time to write poetry, and many of his first pieces, afterwards destroyed, were held by sound judges to be equal to anything he ever did. Both Morris and Burne-Jones had come to Oxford with the intention of taking holy orders, but as they felt their way they both came to the conclusion that there was more to be done in

the direction of social reform than of ecclesiastical work, and that their energies would be best employed outside the priesthood. So Morris decided to become an architect, and for the better propagation of the views of the new brotherhood a magazine was at the same time projected, which was to make a speciality of social articles, besides poems and short stories. At the beginning of 1856 the two schemes came to a head together. Morris, having passed his finals in the preceding term, was entered as a pupil at the office of George Edmund Street, the well-known architect; and on New Year's Day the first number of *The Oxford and Cambridge Magazine* appeared. The expenses of this very interesting venture were borne entirely by Morris, but after the issue of No. 1 he resigned the formal editorship to his friend Fulford. Many distinguished compositions appeared in its pages, but it gradually languished, and was given up after a year's experiment. The chief immediate result was the friendship between Rossetti and Morris which sprang up from a successful attempt to secure the former as a contributor. In the summer of 1856 Street removed to London, and Morris accompanied him, working very hard both in and out of office hours at architecture and painting. But Rossetti persuaded him that he was better suited for a painter, and after a while he devoted himself exclusively to that branch of art. It was in the summer that the two friends visited Oxford, and finding the new Union debating-hall in course of construction, offered to paint the bays. Seven artists volunteered help, and the work was hastily begun. Morris worked with feverish energy, and, on finishing the portion assigned to him, proceeded to decorate the roof. The work was done too soon and too fast, the colours

WILLIAM MORRIS.

(From a photograph by Elliott and Fry, London.)

began to fade at once, and are now barely decipherable; but the broken designs, so long as any vestige remains, will always be interesting as a relic of an important æsthetic movement, and as the first attempt on Morris's part towards decorative art. Early in 1858 Morris published *The Defence of Guenevere*, which was almost unnoticed by contemporary criticism, but is now recognized as one of the pearls of Victorian poetry. Its mediævalism, picturesque and haunting, its unflinching artistic intuition, and its dim, harmonious colouring, as of some exquisite tapestry, are features peculiar to Morris's best work.

On 26th April 1859 Morris married Jane Burden, a beautiful Oxford girl, who had sat to him as a model, and settled temporarily at 41 Great Ormond Street, London. Meanwhile he set about building for himself at Upton a house which was to be the embodiment of all his principles of decorative art. Furniture, decorations, household utensils, and every article of daily use were specially designed, and in the summer of 1860 the house was ready for occupation. The furnishing of it had suggested a fresh activity; Morris now determined to embark upon decoration as

a career. A small company was formed, consisting of Rossetti, Webb, Burne-Jones, Madox Brown, Faulkner, and Marshall, and in January 1862 started business under the title of Morris, Marshall, Faulkner and Co., with offices at 8 Red Lion Square. The prospectus set forth that the firm would undertake church decoration, carving, stained glass, metal work, paper hangings, chintzes, and carpets. The business, after inevitable vicissitudes, flourished, but the "house beautiful" at Upton proved to be unhealthily situated. Serious illness obliged the family to remove to town, and in November 1865 they resettled at 26 Queen Square, Bloomsbury. Morris was now unceasingly busy, but he found time also for literature. In June 1867 he published *The Life and Death of Jason*, which was at once successful; and in April 1868 the first two parts of *The Earthly Paradise*. The rest of this wonderful storehouse of poetic romance appeared in two volumes in 1869 and 1870. In the following year he was again looking for a country house, and lighted upon Kelmscott manor house, in the Upper Thames valley, which he took at first in joint-tenancy with Rossetti, and used principally as a holiday home. Hither he would retire from the cares of business, and take up the country life which was always his particular delight. In 1872 appeared *Love is Enough*, structurally the most elaborate of his poems for its combination of the epic and dramatic spirits; and in the autumn he began to translate the shorter Icelandic sagas, to which his enthusiasm had been directed by two inspiring journeys to Iceland. Business worries, however, interrupted him; it was found necessary to reconstruct the company owing to its having grown out of proportion with the existing division of profit and labour. Long negotiations ensued, and in March 1875 the old firm was dissolved. Morris now became sole manager and proprietor, although the other members of the old firm continued, in varying degrees, to give him the advantage of their assistance and advice.

Meanwhile the epic mood had possessed Morris very strongly, and, in addition to his work upon the sagas, he had actually finished and (in 1875) published a verse translation of the *Æneid*, which is interesting rather for its individuality than for any fidelity to the spirit of the original. Morris's cast of thought was too essentially mediæval to accord well with classicism. In the following year appeared *Sigurd the Volsung*, a version full of heroic vigour, movement, and vitality, but somewhat too lengthy and incoherent in design to preserve the epic interest intact to the British taste. This splendid burst of poetic activity, however, had raised him to a place among the first poets of his time; and in 1877 an attempt was made to induce him to accept the professorship of poetry at Oxford. But he felt himself lacking in the academic spirit, and wisely declined. Mention should be made at this time of a fresh outlet for his energy, furnished by his foundation in 1877 of the Society for the Protection of Ancient Buildings, which sprang into being as a practical protest against a scheme for restoring and reviving Tewkesbury Abbey. He began, too, to take an active interest in politics over the Eastern Question, but his enthusiasm was at the moment a flash in the pan. Finding that events were going against his judgment, Morris, as was so often the case with him, shrugged his shoulders and broke free from the movement. It was never a part of his character to adapt himself to development; if things went awry, he was always apt to lose interest.

Still, although he found it hard to sit close to a definite party, Morris continued to be spasmodically interested in political movements. During the next few years, indeed, the interest gained ground with him steadily. After the general election of 1880 he finally abandoned the Liberal

party, and drifted farther and farther into Socialism. For ten or twelve years the movement had been gaining ground in England, and the Social Democratic Federation was formed in 1881. In January 1883, within a week of his election to an honorary fellowship at Exeter, Morris was enrolled among its members. Thenceforward for two years the cause of Socialism enjoyed not only the advocacy of his spare time, but the thought and energy of all his working hours. For it he even neglected literature and art. In March 1883 he gave an address at Manchester on "Art, Wealth, and Riches"; in May he was elected upon the executive of the Federation. In September he wrote the first of his *Chants for Socialists*, designed to proclaim that "the lower classes must demand a higher standard of life for themselves, for the good of the whole world, and for the regeneration of the conscience of man." About the same time he shocked the authorities by pleading in University Hall for the wholesale support of Socialism among the undergraduates at Oxford. He was now heart and soul in the movement; he had sold some of the treasures of his library to enrich its funds, and was giving it his brain and heart. Nevertheless, the Federation began to weaken. Internal dissensions harassed it. At the franchise meeting in Hyde Park in 1884 it was unable to get a hearing. Morris, however, had not yet lost heart. At the very end of 1884 the Socialist League was founded, and in February 1885 a new organ, *Commonweal*, began to print Morris's splendid rallying-songs. Still, differences of opinion and degree prevented concerted action; and when after the Trafalgar Square riots in February 1886 Morris remonstrated with the anarchic section, he was denounced by the advanced party, and ever afterwards was regarded with suspicion. In 1889 he was deposed from the management of *Commonweal*, and gradually lost all confidence in the movement as an active force. In November 1890 he left the League. The paper went from bad to worse, grew eventually treasonable, and saw its publisher condemned to eighteen months' imprisonment. This was the end of *Commonweal*, and with it the League also fell to pieces.

Long before that time, however, Morris had returned to the paramount interests of his life—to art and literature. When his business was enlarged in 1881 by the establishment of a tapestry industry at Merton, in Surrey, Morris found yet another means for expressing the mediævalism that inspired all his work, whether on paper or the loom. In 1887 he published his translation of the *Odyssey*, which had many of the qualities and defects of his *Æneid*, and is much more interesting as an experiment than valuable as a "Homeric echo." He then added another to his many activities; he assumed a direct interest in typography. *The House of the Wolfings* in 1889 was the first book in which, aided by the Chiswick Press, he tried to beautify the art of modern printing; and in the same year, in *The Roots of the Mountains*, he carried his theory a step farther towards perfection. Some fifteen months later he added a private printing-press to his multifarious occupations, and started upon the first volume issued from the Kelmscott Press, his own *Glittering Plain*. For the last few years of his life this new interest remained the absorbing one. A series of exquisite books, which gain in value every year, witnesses to the thorough and whole-hearted fashion in which he invariably threw himself into the exigencies of his life-work.

The last years of his life were peacefully occupied. He was sounded as to whether he would accept the Laureateship upon the death of Tennyson, but declined, feeling that his tastes and his record were too remote from the requirements of a Court appointment. His last piece of work, the crowning glory of his printing-press, was the

Kelmscott Chaucer, which had taken nearly two years to print, and fully five to plan and mature (see BOOK-PRINTING for a facsimile of a page). It was finished in June 1896, and before it was in his hands he already knew that his working day was over. His vigour had been slowly declining for some time, and he sank gradually during the autumn, dying on the 3rd October 1896. He was buried in Kelmscott churchyard, followed to the grave by the workmen whom he had inspired, the members of the league which he had supported, the students of the art guild he had founded, and the villagers who had learnt to love him.

Essentially the child of the Gothic revival, he had put an ineffaceable stamp on Victorian ornament and design, his place being that of a follower of Ruskin and Pugin, but with a greater practical influence than either. In house decoration of all kinds—furniture, wall-papers and hangings (which he preferred to paper), carpet-weaving, and the painting of glass and tiles, needlework, tapestry—he formed a school which was dominated by his protest against commercialism and his assertion of the necessity for natural decoration and pure colour, produced by hand work and inspired by a passion for beauty irrespective of cheapness or quickness of manufacture.

The truest criticism of William Morris is that attributed to his friend, Mr Swinburne, who said that he was always more truly inspired by literature than by life. His own modest claim to be "the idle singer of an empty day" is often quoted in criticism of him, but it is entirely inadequate. Morris was never idle, nor was his day, either in literature or in art, in any sense empty. But what he clearly lacked, in life no less than in art, was a direct and sincere sympathy with ordinary humanity. His Socialism, though it made a brave show at times, was at heart a passionate enthusiasm for an inaccessible artistic ideal. Morris, indeed, was not primarily interested in men at all, but in objects. His poetry deals, it is true, with the human passions, but the emotion is always seen as in a picture; he is more concerned with the attitude of the group than with the realization of a character. He had very little adaptability in dealing with his fellows; the crowd, as a crowd, carried his enthusiasm, but he was unable to cope with the individuals that composed it. Many of his colleagues bear witness to his generosity and magnanimity, but as a general principle he certainly lacked the wider humanity. This is the one failing of his art: it is also the shortcoming of his poetry. Granted this, there is left an immense amount that will always make demands upon an undivided admiration. The spirit of beauty breathes in every line; a sense of music and of colour is everywhere abundant; the reader moves, as it were, under a canopy of apple-blossom, over a flower-starred turf, to the faint harmony of virginals. Nor does the poet lack power and vigour when an adventurous story is to be told. The clash of arms breaks upon his pagan paradise with no uncertain sound; he is swift in narrative, breathless in escapade. And over all hangs the faint atmosphere of mediævalism, of an England of green gardens and grey towers, of a London "small and white and clean," of chivalry and adventure in every brake. The critic has also to remember the historical value of Morris's literary influence, following upon the prim domesticities of early Victorian verse, and breaking in upon Tennyson's least happy phase of natural homeliness. The period of *Enoch Arden* was one of the least inspiring in modern literature, and it was due not a little to Morris's fine sense of romantic beauty and glamour that the later years of the Victorian age were rescued from commonplace utilitarianism, and dominated by higher issues of art and higher forms of artistic impulse.

See the *Life and Letters*, in 2 vols. (Longmans), by J. W. MACKAIL.

(A. WA.)

Morristown, a town of New Jersey, U.S.A., capital of Morris county, in the northern part of the state, at an altitude of 328 feet, at the intersection of the Delaware, Lackawanna and Western, the Rockaway Valley, and the Whippany River railways. The American army, under Washington, had its headquarters here in the winters of 1776-77 and 1779-80. Population (1890), 8156; (1900), 11,267.

Mortara, a town of the province of Pavia, Lombardy, Italy, an important railway junction in the angle between the Ticino and the Po, 32 miles by rail southwest of Milan. It has fine churches, with pictures by Gaudenzio Ferrari and other artists, and also a technical school. It stands in the midst of a rice-growing region, and has iron-works and manufacture of hats and cheese. Here the Austrians defeated the Piedmontese in 1849. Population, 5100.

Mortlake, a village in the Kingston parliamentary division of Surrey, England, on the Thames, about 6½ miles west of London by rail. It has been associated with the Oxford and Cambridge yearly boat-race since 1845. Population of parish (which includes East Sheen) (1881), 6330; (1891), 7714; (1901), 7774.

Morton, John Maddison (1811-1891), English playwright, was born at Pangbourne, 3rd January 1811, his father, Thomas Morton (1764-1838), being also a well-known dramatist. His name lives as the author of *Box and Cox* (1847), but he also wrote a number of other farces. In later life, however, he failed to maintain his success, and eventually he became a Charterhouse pensioner, and died 19th December 1891.

Morton, Levi Parsons (1824-——), Vice-President of the United States 1889-93, was born at Shoreham, Vt., on the 16th of May 1824. After an academic education he went into business. He was uniformly successful as a merchant in Hanover, N.H., and at Boston; and in 1863 he founded a banking house in New York, which has become one of the strongest in the country, and of which, till his retirement, he was the head. With little previous activity in politics, he was elected to Congress as a Republican in 1878, and again in 1880. In 1881 he was appointed minister to France, where he served till 1885. Three years later he was nominated for the Vice-Presidency on the ticket with Benjamin Harrison, and was elected. In 1894 he was elected governor of New York by a majority of more than 150,000 over his Democratic competitor, Mr Hill. His two years' service as governor terminated his political activity. Since 1896 he has lived in retirement.

Morton, Oliver Perry (1823-1877), American politician, was born in Wayne county, Indiana, on the 4th of August 1823. He received a college education, and began the practice of law in 1847. In early life a Democrat, he joined the Republican party at its formation, and was elected lieutenant-governor of Indiana in 1860. The governor-elect having resigned, Morton took his place in January 1861, and displayed in connexion with the demands of the Civil War a remarkable degree of vigour and resourcefulness. After a second term as governor, he was sent to the United States Senate, in which he served from 1867 till his death. Prior to the Presidential election of 1876, he laboured strenuously but in vain for the enactment of a law regulating the electoral count. When for lack of such a law the dispute arose as to the method of counting the votes, he took a leading part in the controversy; and though he opposed the Bill creating the Electoral Commission, he served as a member of that body. He died at Indianapolis on 1st November 1877.

Morvi, a native state of India, in Kathiawar, within the Gujarat division of Bombay, situated south of the Gulf of Cutch and the Little Rann. Area, 821 square miles; population (1881), 89,964; (1891), 105,335. The estimated gross revenue is Rs.11,25,390 a year, of which Rs.3,36,530 was expended on public works in 1897-98; tribute, Rs.61,559. The chief, whose title is Thakor Saheb, is a Jareja Rajput, of the same clan as the Rao of Cutch. A steam tramway, constructed at the cost of the state, runs from Rajkot through Morvi town to the seaport of Wawania, and also to Wadhwan (94 miles). Owing to long-standing disputes with the state of Cutch, the collection of customs duties at Wawania is under British management.

The town of Morvi is situated in 22° 49' N. and 70° 53' E., on the river Machhu, 22 miles from the sea and 35 from Rajkot. Population (1881), 15,353; (1891), 16,325. Its high school had 304 pupils in 1896-97. There is a cotton mill, with 36 looms and 1664 spindles. The state printing-press issues a gazette.
